In the esparto store and cleaning department, room is provided for the storing of over 2000 tons of esparto grass; it also contains the machinery for the mechanical cleaning, and for the opening out of the grass preparatory to boiling.

Rag stores and sorting rooms.—The rags are sorted into grades and passed through the revolving chopper and duster for the purpose of removing mechanical impurities. They are afterwards conveyed to the rag boilers.

Boiling and washing.—The department contains one large spherical boiler for the boiling of rags, eight stationary boilers for the boiling of esparto grass, and the washing pans. After the boiling and the preliminary washing, the esparto is conveyed to special washing engines for the final washing. After this it is bleached in the poachers.

Water purification.—Battery of filters, with pumps, &c., for treating 40,000 gallons of water per hour.

Chemical wood pulp breaking and bleaching department.—Mixing of the different kinds of "chemical wood" (wood cellulose), and opening out of the pulp in two breaking engines. Four large bleaching engines, each capable of holding three tons of cellulose at one time, are provided for the bleaching of the chemical wood pulp. To ensure cleanliness these engines are lined with white tiles. The bleached pulp is passed to the draining house, where the excess of water is removed. The rags are also bleached in this department in a separate engine.

Draining of bleached material.—This building contains nine large drainers, lined with white and cream coloured tiles. After draining, the material is filled into wagons and conveyed to the beating engines. The waste water from the paper machines is passed through filter presses for the purpose of removing the fine fibres and solid matter which it contains. In this manner considerable economy is effected, and these substances are prevented from contaminating the mill effluent. *Press pate or half stuff machines.*—The bleached esparto fibres are passed over a series of settling traps and through mechanical strainers

so as to remove sand, particles of roots, and other foreign matter; they are then passed over the "press pate," and formed into sheets, which are afterwards conveyed to the beaters, in which the fibres are drawn out and disintegrated, so as to make them suitable for the manufacture of the various classes of paper.

Waste paper breaker.—In this department waste paper is reduced to the state of pulp, and is then added to the ordinary paper pulp in the beating engines.

The pulp coming from the beaters is passed to the pulp chests, in which it is mixed with the necessary quantity of water. From here it is conducted over the sand tables and through the revolving strainers on to the endless wire band of the paper machine. The water is gradually removed, and the web of paper formed. The moist web after leaving the endless wire band, now passes between a series of press rollers, by means of which a further quantity of water is pressed out, and it is ultimately conducted over the drying cylinders. A passage through calenders gives the paper the required finish. A still higher finish is obtained by passing the paper through the super calenders.

Soda recovery plant. Multiple effect evaporation.—The waste lye from the esparto boiling is concentrated to about 50° Tw., and afterwards incinerated in a revolving furnace. The "black ash" obtained is finally converted into caustic soda by causticising.

THE MANCHESTER SHIP CANAL DOCKS AND THE CORPORATION SEWAGE WORKS, DAVYHULME.

Leader: Dr. G. J. FOWLER.

The Rivers Department of the Manchester Corporation have charge of all the arrangements for treatment and disposal of sewage, a task of enormous difficulty. A vast sum has been spent in the endeavour to deal with the sewage problem, and the Committee believe they have found a satisfactory solution. Including storm water, the average daily flow of sewage for the year 1901, which may be taken as indicative of other years, was 34,071,019 galls., whilst the average daily dry-weather flow was 25,700,000 galls. Until the last few years the treatment was by chemical precipitation, but this is now rapidly giving place to the bacterial system.

SIR W. G. ARMSTRONG, WHITWORTH AND CO.'S WORKS, OPENSHAW.

Leader: Mr. W. H. COLEMAN.

These works were founded by the late Sir Joseph Whitworth, who began business in Manchester in 1833. They were built in 1880, and have been greatly extended since that time. The total area covered is 40 acres, and an additional 12 acres have recently been acquired for the purpose of further extension. In 1897 Whitworth's firm amalgamated with the great Tyneside shipbuilding firm founded by the late Lord Armstrong. Many of the famous tools and machines invented by Whitworth are still manufactured here. These include surface plates, screw threads, measuring machines, and sundry machine tools. Great ingenuity was displayed in his inventions in connection with the manufacture of rifles, large guns, steel guns, and armour plate. The present establishment at Openshaw comprises departments for engineering, machine tools, gauges, guns, gun mountings, and armour plate, steel works, crucible steel department, iron and brass foundries, tinsmiths' shops, pattern makers' department, metal testing department, laboratories, producer gas plants, two complete ammonia recovery plants, general offices and drawing offices. The number of hands employed is 4,163.

THE CORPORATION ELECTRICITY WORKS, STUART STREET.

Leader: Mr. W. H. COLEMAN.

The area of the works is about eight acres. Three-phase alternating currents, with a frequency of 50 cycles per second, are generated at the main power house at an extra high pressure of 6,500 volts, and are transmitted at this pressure to the sub-stations. The supply from the sub-stations is at 500 to 550 volts pressure for supplying to the tramways, and at 410 and 205 volts pressure for lighting and power purposes.

The plant in the engine room consists of six main 1500 kilowatt three-phase alternator sets. Each of the main engine sets consists of a 2500 i.h.p. vertical cross-compound engine running at 94 revolutions per minute, and a 1500 kilowatt three-phase alternator, generating current at a pressure of 6500 volts with a periodicity of 50 cycles per second. The high pressure and low pressure cylinders of the engine are 36 in. diameter and 71 in. diameter respectively, by 3 ft. 6 in. stroke. They are steam jacketted, and are fitted with Dobson's "Corliss" valve gear. Over one hundred miles of cable are required for connecting the sub-stations with the generating station.

The extension plant at Stuart Street Works consists of two 6500 h.p. triple expansion engines, and twelve Babcock and Wilson boilers. The engines are run condensing, and the cooling towers are by Messrs. Klein's, Messrs. Koppel, and the Wheeler Condenser Company. The total horse-power at Stuart Street is 28,000 h.p.

Opportunities were also given to members for visiting the following institutions: The University, Municipal School of Technology, Art Gallery, The John Rylands Library, Chetham Hospital and Library, and the Whitworth Institute.

THE ANNUAL DINNER.

The annual dinner was held at the Grand Hotel, Aytoun Street. Dr. E. Divers, the President, presided, and he was supported by Mr. Eustace Carey (President-elect), Alderman I. Frankenburg (Mayor of Salford), Alderman Sir James Hoy, Alderman Sir Bosdin T. Leech, Sir W. H. Bailey, Mr. Ivan Levinstein, Mr. J. H. Reynolds, Professor Schuster, Dr. D. B. Hewitt, Professor W. R. Lang, Mr. Thomas Tyrer, Alderman Joseph Thompson, Mr. O. Guttmann, Dr. Julius Lewkowitsch, Dr. L. Baekeland, Dr. K. E. Markel, Mr. C. E. Groves, Professor W. J. Pope, Mr. J. Crosfield, and the Hon. Secretary, Mr. Julius Hübner.

The CHAIRMAN said, before proceeding with the toasts set down on the programme, he desired, on behalf of the Society, to express their thanks to Messrs. Joseph Crosfield and Sons, for the privilege of inspecting their works, for the admirable arrangements made for the inspection, and for the hospitality extended throughout the day.

Dr. K. E. MARKEL acknowledged the expression of thanks on behalf of himself, his co-directors, and the staff employed by the firm.

The CHAIRMAN proposed "The Health of the King."

The CHAIRMAN expressed regret at the absence of the Lord Mayor of Manchester, owing to a long-standing engagement, but he was glad to see they had with them His Worship the Mayor of Salford (Alderman Frankenburg), and they had also Sir James Hoy, who had come there partly in consequence of the absence of the Lord Mayor, in order that he might show attention to them on behalf of the City of Manchester. They had also Sir Bosdin T. Leech, an ex-Mayor of Manchester, and they had also that well-known citizen and ex-Mayor of Salford, Sir William Henry Bailey.

After a telegram which had been received from Dr. Ludwig Mond, acknowledging receipt of the Society's medal, had been read,

Dr. DAVID B. HEWITT, in proposing "The City of Manchester and the Borough of Salford," paid a high compliment to the admirable manner in which their affairs were managed. There had been a succession of most able Mayors and Lord Mayors of the two towns that ought, in his opinion, to be one. Both places had exhibited a vast amount of enterprise in various directions, and the only fault he could find with them was that they had not paid sufficient attention to sewage purification. In that respect neither of the towns was what it ought to be, but he hoped there would be a change within the next few years.

Alderman Sir JAMES HOY, in responding, said that in the various phases of municipal life Manchester had done fairly well, and was not behind other places. In the last two or three years much wider demands had been

made on municipalities than had been the case in the past. Alongside these demands was the growing necessity for economy. To his mind the question of making life worth living to a community was one of the greatest problems that any body of men could have entrusted to them.

Alderman FRANKENBURG (Mayor of Salford) admitted that Manchester was a glorious city, and if to that they would add "ancient and royal," they could imagine what Salford was like.

Sir WILLIAM BAILEY also responded.

Sir BOSDIN T. LEECH gave "The Society of Chemical Industry." Alluding to the sewage purification problem, he remarked that if Manchester had not been restricted by the Local Government Board, and had been allowed to fully adopt the advice of its chemical advisers, the city would by now have had a perfect sewage scheme. He coupled the toast with the name of the President, and complimented him on the success of his efforts to impart chemistry to the Japanese.

The CHAIRMAN, in replying, said that Japan, with which Sir Bosdin Leech had associated him in too complimentary terms, largely owed its success to the fact that it had applied science to the business of life—to the army, navy, and education.

Mr. EUSTACE CAREY, President-elect, said it was a great pleasure to him to think the Society had "come of age," but it would be some years before they arrived at maturity, as they had a great future before them, and a great deal of work to do. Their first interest was in applied science and technology; at the same time they were not only chemists so far as their ability would permit them to be so, but they were also business men. In order to manufacture products they must needs come in contact with railways and canals, and they had to consider the question of rates, and he hoped the time was not far distant when they would be in a similar position with regard to carriage as they were in France and Belgium, where the canals were like our high roads, absolutely free from toll. They also came into contact with the Government on the Alkali and other Acts, and, while he did not complain of anything which the Government had done, he wished to point out that their business as chemists had to deal with something more than technology. He thought they must in future give more attention to subjects of general interest, and be alive to what was contemplated by the Government of the day, and do their best to promote the interests of the manufacturer in the United Kingdom and other countries where their Society was so well-known. He was pleased with the efforts which had been made to bring the members together by visiting the various works, which not only gave opportunities for members becoming known to each other, but also removed that feeling of secrecy which had unfortunately too long prevailed in this country. By inspecting various operations, and by the interchange of opinions, they would eventually make their beloved Society of Chemical Industry more important even than it had been in the past.

Dr. K. E. MARKEL, in proposing "The University of Manchester," said he approached this toast with a certain amount of diffidence, but he claimed to have one qualification for the task in his unbounded admiration for the University. Well did he remember, as a boy in Germany at school, purchasing with his first pocket money two English scientific books—Roscoe's "Elementary Chemistry" and Tyndall's "Heat." On the title page of one of the books he read that the writer was Prof. Roscoe, of Owens' College, and boylike, he wondered what sort of a place Owens' College was. Coming to England, he very soon became intimately acquainted with it, and ever since he had taken a very great interest in the institution, and particularly the far-reaching effect of the science taught there on chemical industries. The little book he referred to had created a thirst in him for science which had never been quenched, and which he hoped never would be, as long as he lived. If the University could have such an effect on the humble foreigner far away, what must be the influence on its immediate *alumni*. He need only mention Frankland, Perkin, Schorlemmer, Roscoe, and Dixon, to show the influence which the University had had in the chemical world. It would be futile for him, in the presence of so many who were far more intimately acquainted with the University than he was, to speak further of its influence, but he could say this, that Manchester was the first city that had really recognised the necessity of co-ordinating all the higher educational institutions and grouping them round the University, and, what was more, it had forced other towns to follow its example. He coupled with this toast "The Municipal School of Technology," that splendid Institution with its magnificent laboratories, and its excellent staff, of whom they had the privilege of having two on their Council, Messrs. Hübner and Pope.

Prof. ARTHUR SCHUSTER, responding to the toast of "The University of Manchester," said, from the information they had already received that day, they might have gathered that the University and the Society of Chemical Industry were really sisters, for one of the fathers of the Society was also one of the fathers indirectly of the University. They began their birth from the time that they really became identified with the City and became the University of Manchester, and this enabled them to become more closely associated with the various interests of the City. He had read in the newspaper that morning that the Minister of Education hoped to establish an educational ladder, by means of which every boy or girl might ultimately pass from the elementary school to one of the ancient Universities. He quite agreed that, if education is to end at the University, it must be an ancient one. They claimed that their University was a modern one, and therefore education only began there, and it was carried on after the boy or girl left the University and commenced practical life. We are taught, however, that the education of a man of science practically begins when he enters upon a trade. He thought Manchester could claim that it always kept its eyes open, and one of the conditions of a modern University was, that there was a certain danger of students of any particular profession being kept too much in contact with their own subject. In their own University, they were trying to overcome that difficulty, and bring their students into close contact with each other.

Mr. IVAN LEVINSTEIN, speaking to the toast of "The University," said he was sure there was no Society which took a deeper interest in science and its application than the Society of Chemical Industry. They had seen their great School of Technology built by the ratepayers of Manchester, and, while Prof. Schuster had referred principally to pure science as taught in the University, he might say that the establishment of a Faculty of Technology was largely due to Prof. Schuster. The purely scientific chemist, seeking to solve problems, was quite regardless of time and expense and regardless of the demands of the public, whilst the technologist, who did not care so much for seeking the truth and nothing but the truth, had to consider the requirements of the market, and the saving of time and cost of production. Such investigations could not be successfully carried out in an ordinary laboratory, especially in the textile and allied industries, and for this reason the Municipal School of Technology had been erected and equipped with laboratories and workshops containing complete plant and machinery such as the student would meet on entering bleach-, dye-, print- and paper-works, spinning and weaving mills, &c. Proof of the advantage of such a system was afforded by the success achieved by students of the School of Technology, who had entered for the degree in technical science at the University.

Dr. JULIUS LEWKOWITSCH, in proposing "The Manchester Section," said he was associated with this particular Section some four years ago, and he was proud to say the only friends he had in Manchester at that time were members of the Section, a Section which, in those days, devoted much attention to smoke and sewage. He coupled with the toast the name of the Hon. Secretary, Mr. Hübner, and expressed sympathy with the Chairman (Dr. Bailey) in his absence through illness, and expressed thanks to both of these gentlemen for their efforts, which had resulted in such a successful meeting.

Mr. JULIUS HÜBNER, in responding to the toast, expressed his indebtedness to Dr. Lewkowitsch for the

very complimentary references which he had made as to his association with the Manchester Section, and the satisfactory arrangements which had been made for the entertainment of the visiting members and their friends. He also wished to acknowledge his indebtedness to the Lord Mayor and the Manchester Corporation, and to the various firms who had so freely extended their hospitality, and which had in such a large measure added to the success of the meeting.

Mr. THOMAS TYRER, in submitting "Our Guests," said the toast needed no elaboration by him. He might make a supplementary remark of regret that Dr. Ludwig Mond, the recipient of the Society's medal this year, was not with them, and they could only hope that the causes which led to the recommendation of his medical adviser not to undertake the journey had passed away. He asked their acceptance of the toast committed to his care, *viz.*, "Our Guests." They had heard some of them that night, and while they honoured them, they nevertheless must have felt honoured in being associated with the Society. The guests were many, including Sir James Hoy, the Mayor of Salford, Sir Bosdin T. Leech, and many others, and it was his pleasure, on behalf of the Society, to heartily welcome them. He coupled with the toast the name of Alderman Joseph Thompson, LL.D.

Alderman Thompson having left, the CHAIRMAN called upon Sir William Henry Bailey to reply.

THIRD DAY. FRIDAY, JULY 13TH.

The party travelled by special train to Hope, whence brakes took them to Castleton. Here the Great Peak Cavern was inspected, after which luncheon was served at the Peak Hotel. It had been intended to drive to Hathersage and the Surprise View, but the weather became unfavourable, and rain fell for the rest of the day. A large room belonging to the hotel, nevertheless, enabled a pleasant afternoon to be spent, to which the excellent singing of the Misses Johnston, daughters of the proprietor of the hotel, contributed. A small number, braving the weather, contrived to visit the Blue John and Speedwell mines. After tea the party returned to Manchester.

In the evening a conversazione was held in the Whitworth Hall of the Victoria University, where Vice-Chancellor Hopkinson received the guests. In the Chemical Lecture Theatre Professor Harold B. Dixon gave a lecture on South Africa, illustrated by lantern slides, and in the chemical laboratories were shown exhibits of scientific and industrial interest by the professors, demonstrators, and students of the University, and others.

New England Section.

Meeting held at Boston, Mass., on Friday, April 6th, 1906.

A paper was read on the "De-arsenication of Sulphuric Acid" by Mr. Hervey J. Skinner.

New York Section.

Meeting held at Chemists' Club on Friday, May 25th, 1906.

MR. RUSSELL W. MOORE IN THE CHAIR.

PINACHROMY AND PINATYPE: NEW PROCESSES OF COLOUR PHOTOGRAPHY.

BY M. A. METZ.

Dr. E. Koenig, of the Farbwerke, vorm. Meister, Lucius and Brüning, has developed two new processes in colour photography which are known, respectively, as "pinachromy" and "pinatype." They are not only of interest to the student of chemistry and physics, but are a distinct and important advance towards the reproduction of objects in their natural colours.

In pinachromy, three collodion films are successively superimposed and coloured by the action of light on certain sensitive chemical preparations with which the films are coated, thus making a true coloured photograph. The process has met with considerable success abroad, and is based on the light sensitiveness of the leuco-bases of the organic dyestuffs. While many of these leuco-bases, for instance those of the safranines, are so oxidisable that they cannot be isolated in a free state, there are others, like the leucomalachite green, which can be easily produced, and are comparatively stable. These more permanent leuco-bases, when exposed for some time to light, become strongly coloured.

Dr. Koenig examined all the leuco-bases at his command, but found that when exposed to light, either by themselves, or in gelatin coatings, none of them gave results of the desired strength or brilliancy. Subsequently he selected collodion as the support, and thus obtained the desired increase in sensitiveness, the leuco-bases, in the presence of collodion, becoming strongly oxidised after a comparatively short exposure. This increased reaction he attributed to the presence of the nitric acid groups in the nitrocellulose, and upon further experiment found that, like nitrocellulose, all nitric acid esters would react. The nitrous acid esters, on the contrary, and the isomeric nitro derivatives of the aliphatic and aromatic hydrocarbons proved ineffective. The nitrosamines showed reactions similar to, but weaker than, those of the nitric acid esters. It is of interest that the light sensitiveness of the mixture of nitrocellulose with the leuco-bases is considerably reduced by the presence of urea or of antipyrine. This would seem to point to the fact that the leuco bodies are oxidised by nitrogen oxides, which separate from the collodion. While nitrocellulose is by no means the most effective of such compounds, still greater sensitiveness resulting from the admixture of leuco-bases with the nitric acid esters of glycerol, glucose or mannitol, it is the most suitable compound, as it acts at the same time as the film and as the support for the picture. The light sensitiveness of the mixture of nitrocellulose and the leuco bodies can be considerably increased by the addition of nitromannitol.

Blue pictures are produced with leucosetocyanine, which is *o*-chlorotetraethyldiaminotriphenylmethane; green with leucomalachite green, or with *m*-nitro- or *m*-aminotetraethyldiaminotriphenylmethane; red with *p*-leucoaniline, or leuco-rhodamine; violet with hexamethyl-*p*-leucaniline (the leuco-base of Violet 6 B crystals), and yellow with leucofluorescein or leucoflavaniline. The fixing of the picture is effected with dilute organic acids, of which monochloracetic acid is the best; acetic acid or di- or tri-chloracetic acids cannot be used.

The practical application of this process is as follows:—A sheet of paper is coated with the blue collodion mixture and exposed under its corresponding negative. When the blue picture appears sufficiently strong, it is fixed in a 10 per cent. solution of chloracetic acid, washed, coated with a thin gelatin film, and dried. This gelatin film serves to protect the first collodion coating from dissolving when the second coating is put on. The dry blue picture is then covered with the yellow collodion mixture and exposed under its corresponding negative, care being taken that the pictures register accurately. After exposure, it is fixed, washed and dried, and the yellow picture produced. The final red picture is obtained in a corresponding manner. On account of the complete transparency of these very thin films, and the brilliancy of the colours produced, the prints appear very uniform. The fastness to light of pinachromy pictures is naturally not absolute, but the dyestuffs used are relatively fast. The poorest is the blue, but even this surpasses the "blue prints" (cyanotypes) in fastness. The quantity of the leuco bodies necessary is extremely small; hence pictures composed of the three-colour films cost but a trifle more to produce than ordinary gum or pigment prints.

In pinatype, the second process, on the other hand, a single gelatin film is so treated that a succession of paper prints may be obtained from the coloured plate as often as desired. This makes pinatype especially adapted to three-colour work, and it is now being carefully tested for this purpose. A bichromated gelatin plate is exposed to light under a photographic negative, and the undecomposed bichromate is removed by washing. Pinatype dyes have the property of dyeing the unhardened gelatin very strongly, whereas the hardened portions are either not coloured at all or very slightly. If moist paper, coated with specially prepared gelatin, is now brought into intimate contact with the gelatin layer, coloured by means of a pintapye dye, in a short time a coloured paper picture with all the half tones is obtained, which appears strongly coloured on those parts not affected by light, while the most exposed parts remain white. From this it is evident that in order to obtain a positive picture the bichromated gelatin layer must be exposed under a diapositive. The facility with which enlarged copies can be made is especially important for three-colour photography, as the direct production of large-sized plates in three colours offers many technical difficulties. By this process the negatives can be enlarged directly, whereby all the details are much better preserved than when an enlarged negative has to be prepared from the original negative. The print plates for pinatype, which are not sensitive to light, are steeped with the film side uppermost, for three or four minutes, in a sensitising solution (2 grms. of chromic acid dissolved in 110 c.c. of water) in shaded daylight or lamplight. The solution must not be warmer than 20° C. Any bubbles of air should be removed with the finger or a brush. A great number of plates may be sensitised, one after the other, in the same bath. After the plates have been sensitised, they are well drained and dried in a dark and not too warm place, free from dust. The sensitised plates keep much longer than sensitised pigment paper, and preserve their qualities completely for two or three weeks. The diapositives to be copied are laid in a frame with the film side in contact with the film side of a sensitised print plate. The exposure time for a print plate is about the same as that for collodion paper. Electric arc light is just as good as direct sunlight for copying. After copying, the pictures should be distinctly seen in brown colour on a yellow background. The print plate is now washed in running water until all undecomposed chromic acid has been removed. Usually washing is complete in ten minutes. The plates may now be dried or placed directly in the dye solution. The well-washed print plate, either dry or moist, which corresponds to the red filter negative, is steeped in the blue dye solution composed of 5 grms. of "pinatype blue" dissolved in 250 c.c. of water, and the dish rocked from time to time. The first dyeing takes about 15 minutes. The plate is then washed and rinsed until the water running off from it is no longer coloured. It should have the appearance of the diapositive full of detail, with almost transparent whites and intense shades. When the dyed plate is finished, a piece of transfer paper of the size of the plate is softened in cold water, all air bubbles being removed, until the paper has become completely pliable and fully stretched. The paper is now attached to the plate, preferably under water, with the film side against the film side of the printed plate, and both removed from the bath, at the same time draining off the excess of water by a gentle motion of the hand. The plate is then laid upon a table, paper uppermost, and protected with a piece of oiled silk or the like, and the paper firmly smoothed over with a rubber squeegee, from the middle outward, using moderate pressure. The operation is similar to that in the pigment process. When the paper adheres satisfactorily it is covered with a damp sheet and a glass plate, in order to prevent evaporation, and the whole allowed to stand 10 to 15 minutes, if desired, under a light weight. At the end of this time the picture will be found transferred to the paper with sufficient strength. The paper is now removed and hung up to dry. The print plate is now again placed for about five minutes in the dyebath, rinsed, and the picture again transferred to paper as above directed. These operations may be repeated as often as desired. By repeated immersion in the dyebath the print plate becomes darker. Nevertheless, the prints from the plate are quite uniform, as only the exterior surface of the dyed plate has action on the paper. The dyed plates may be kept for any length of time after use, and can be again employed after a fresh immersion in the dyebath. The dyeing of the print plate corresponding with the green filter negative is done in the same manner. For the dyebath 5 grms. of "pinatype red" are stirred with a little water to a paste, and then 3 to 5 c.c. of concentrated ammonia solution added. Sufficient ammonia must be used to completely dissolve the dye to a clear deep red solution. After about five minutes the solution is diluted with cold water to 250 c.c. After the red plate has been washed free from the excess of dyestuff, the blue picture is softened in water and laid under water upon the red print plate. The operation is carried out in the same way as before described, the blue picture being easily shifted under water, so as to exactly correspond to the red print plate. When the adjustment is complete, the paper is held firmly against the plate with suitable clamps, leaving the film free. The film is then withdrawn, water again run over the plate, and the paper pressed firmly down with the squeegee. It is allowed to stand for 10 to 15 minutes, and the paper then removed from the plate. About 30 minutes should be allowed for the first immersion of the print plate, corresponding to the blue filter negative, in a dyebath composed of 5 grms. of "pinatype yellow" dissolved in 200 c.c. of hot water; for subsequent immersions, five to ten minutes. The yellow transfer upon the blue and red picture takes about 30 minutes. It is advisable to moisten the superimposed damp sheet well in order to prevent the films adhering to each other. To increase the picture's fastness to light, and to harden the gelatin layer, the paper is now immersed for about one to two minutes in a fixing bath of 2 grms. of fixative chromium salt and 100 c.c. of water. After fixing, the picture is washed for about five minutes in clean water and hung up to dry.

The principal advantage of pinatype lies in the use of print plates, which are prepared in a simple manner with the aid of light, allowing the preparation of a large number of paper copies therefrom by a purely mechanical process, without further resource to light. The print plates can be kept and used again at any time, without the aid of light, for the preparation of paper copies. In consequence of the intensity of the pinatype dyestuffs and the immunity from spoiled pictures, pinatypes are very cheap. Pinatypes are extremely fast to light. A three-coloured pinatype is not composed of different films. A single thin film carries all of the colours, which therefore blend harmoniously.

Papers were also read by Maximilian Toch on "Modern Three-colour Processes," and by Hoyt Miller on "Three colour Photography."

Nottingham Section.

Meeting held at Nottingham, on Monday, May 28th, 1906.

MR. J. M. C. PATON IN THE CHAIR.

A NEW BOTTLE FOR CULTURES.

BY J. GOLDING.

At a recent meeting of this section, Mr. Droop Richmond showed me a flat-sided bottle which he was using for cultures instead of Petri dishes. The bottle was very portable and convenient, and had the additional advantage of being much cheaper than the Petri dish. By placing the gelatin uppermost it can be used for anaërobic cultures if alkaline pyrogallic acid is put on the under side. It

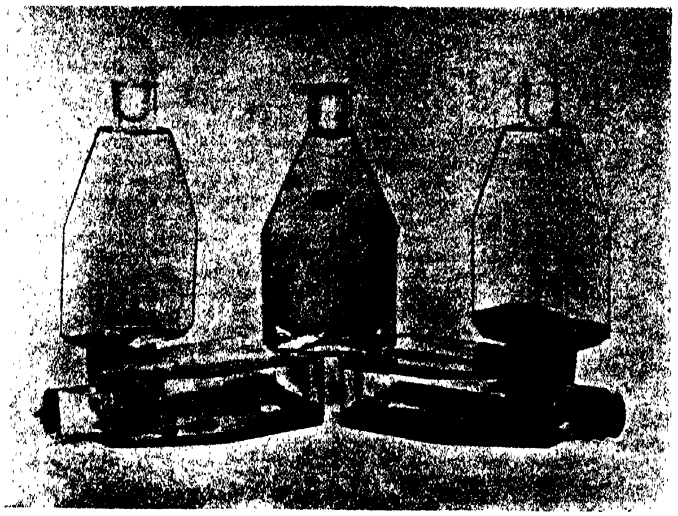

FIG. 1.

was, however, rather too thin to allow of stopping the liquefying growths with silver nitrate, a very convenient practice which I owe to Prof. Hiltner, of Munich. I therefore designed the bottle shown in Fig. 1, which was made for me by Messrs. A. Gallenkamp, of London.

The sides of these bottles are as flat as they could be made. The shoulders taper off so that a straight platinum needle, or a specially-designed silver quill holding a stick of silver nitrate, can reach any colony growing on the gelatin.

Method of using.—The bottle is first cleansed, plugged with cotton wool, and sterilised, 20 c.c. of nutrient gelatin or other medium are then added, and the bottle sterilised again. When required for use the bottles are placed in warm water to melt the gelatin, and kept just warm enough to keep it liquid.

The water, soil, or other substance to be analysed, is so attenuated in sterile distilled water that 1 c.c. contains not more than 100 organisms.

One c.c. of this attenuated liquid is then run into the melted gelatin, well shaken, and the bottle laid on its side to set.

When liquefying colonies grow, sub-cultures may be made from them, and from colonies in their immediate neighbourhood, or if a count only is desired, these colonies are noted and then stopped with silver nitrate. The remaining colonies can then go on growing till large enough to count.

If it is desired to make an anaërobic culture, the bottle is turned over when the gelatin has set, and a solution of pyrogallic acid introduced; the bottle is then slightly raised, and a small stick of potash introduced; the mouth is then tightly corked with a rubber stopper, and the acid allowed to come in contact with the soda.

A NEW FRACTIONAL CONDENSER FOR STEAM.

BY J. GOLDING.

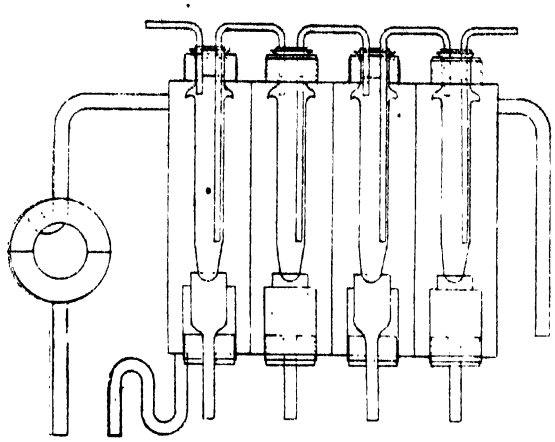
I have for some time been in want of a good supply of pure distilled water for pot and water cultures, and for use in the chemical and bacteriological laboratories at the Midland Agricultural and Dairy College. It was necessary that this water should be quite free from traces of metals which are well known to affect the growth of plants and bacteria, and also that it should be as free as possible from traces of ammonia.

The laboratories at Kingston are supplied with gas (made from gasolene), which for the purpose of making distilled water is too expensive.

Steam from a large boiler some thirty yards from the laboratory, used for heating a drying oven and condensed in a copper condenser, gave impure condensed water. This condensed steam contained much ammonia, not easily driven off by boiling, organic substances which gave it a strong taste and smell, also traces of copper from the condenser.

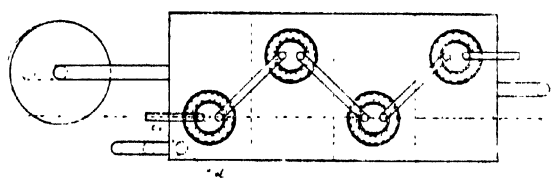
As the water in the well at Kingston which supplies the laboratory and the boiler contains much gypsum in solution (some 220 parts total hardness per 100,000), the pressure steam could not well be used as a source of heat for boiling water to feed a condenser.

I therefore designed the following modification of Bousfield's apparatus (Journal Chem. Soc., 1905, 740).



The condenser consists of a copper box 12 ins. long by 5½ ins. wide by 9½ ins. high. It is divided into four compartments, which communicate with each other by narrow slits on alternate sides of the box. Through the top of each of these compartments passes a tube of Jena glass, which can be cooled by tap water. Under each tube is a cup of Jena glass. The tubes are so designed that condensed water from the top of the box should fall clear of the cups.

The box is tin lined throughout, and the steam enters through a splash trap, also tin lined.



This condenser did not at first give good results, as the steam came out through the cups and brought with it the more volatile impurities. This was got over by jointing them to a longer piece of Jena glass tube bent to form a trap.

The condensed steam, though much more pure, still contained some ammonia and was not quite free from smell and taste. I therefore removed the tube nearest to the steam inlet and substituted for it a dropping funnel containing dilute sulphuric acid (about 10 per cent.) and pure potassium permanganate (about 3 per cent.). This liquid was allowed to stand in the funnel, and was run through and through the separating funnel till nearly decolorised.

This produced the desired effect, and the water from the tubes gave hardly any colour with Nessler solution; the purest in this respect being from the tube nearest the

ELEVATION.

PLAN.

steam inlet; but even the third tube contained less than 0·01 part ammonia per 100,000.

Through the kindness of Dr. Sand, I was enabled to determine the conductivities of the water at the University College, Nottingham, but great difficulty was experienced in bringing the samples into Nottingham. Good results were at last obtained by drawing out the necks of small Jena flasks, filling them with water from the condensers, boiling and emptying this water away, then again filling them and quickly sealing up the necks.

Ordinary good distilled water, according to Bousfield, has a conductivity of some 5 to 10 reciprocal megohms per cubic centimetre. While water prepared by Stas' process of re-distillation only falls just below 1 reciprocal megohm.

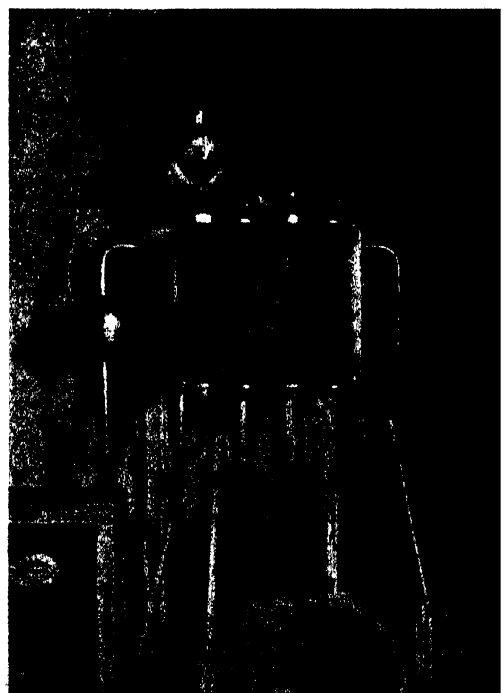
A series of conductivities for water brought in in these flasks worked out at—

Tube	1.	2.	3.	Box.
K 18	1·3	2·3	2·3	4·3 reciprocal megohms.

The quantity of water yielded was also satisfactory, and amounted to 4¼ to 4½ litres per hour from the three tubes.

The yield from the different tubes per hour was as follows:—

Tube 1.	2.	3.	Box.
1520 c.c.	1510 c.c.	1210 c.c.	650 c.c.



In the earlier experiments with the four tubes, 5 litres per hour were obtained.

The condenser was made by Bender and Holbein, Munich.

In conclusion, I wish to express my thanks to the Government Grant Committee of the Royal Society, as this condenser was purchased with a grant made by them for researches on nitrogen assimilation.

Mr. GOLDING, in reply to various questions, said he had not made out the cost of making distilled water by the apparatus. The apparatus cost £5, which was very much under the cost of many other forms of condenser which would not condense the same amount of water. It simply condensed the waste steam, so that the cost was very little beyond the original outlay. Where the supply was short, the water used to condense the steam could be cooled and used over and over again. As to Dr. Caven's question in regard to the use of permanganate, he thought that the idea of using permanganate might be developed so that all organic matter might be got rid of. He must own that he often got in the boiler steam a slight taste, most from the third of the tubes, as the permanganate as now used did not destroy all the taste. There was some volatile organic substance left; but he did not exactly know what it was. The taste, however, did not interfere with the conductivity.

At first, he tried sulphuric acid for absorbing the organic matter and ammonia, but it did not seem to answer so well. Instead of blowing steam through the solution, he thought it would be better to let the acid trickle over a series of funnels placed in the first chamber.

Meeting held at Glasgow, on Tuesday, March 6th, 1906.

MR. DAVID PERRY IN THE CHAIR.

METHODS OF FIRING A POTTER'S KILN: EFFECTS OF HIGH TEMPERATURES ON CLAY.

BY J. ARNOLD FLEMING.

The increased demand which has arisen in recent years for more decorative articles has necessitated the employment of higher temperatures and greater precautions in firing; at the present time, large numbers of articles are worked upon at the same time, using the same clays, which are subjected to the same treatment, and these must be fired so as to obtain the desired results as regards colour, size, and durability.

The general construction of a potter's kiln has remained very much the same for now over 100 years. The fires—of which there may be 10—are situated in the circumference of the base of the oven. The heat enters by "bags" built up inside, and by flues, running more or less horizontally in the bottom or floor of the kiln, entering a well hole in the centre of the bottom; it then enters the firing chamber and ascends through bungs of "seggars" full of the clay articles to be fired to the crown of the kiln, where it is liberated into the air, or controlled by dampers as occasion requires. The air regulator controls the amount of air to be introduced, and by careful manipulation by the fireman, forces the heat through the flues, thus heating the centre of the firing chambers as well as the "ring," or portion immediately above the fires.

The potter's oven, or kiln, is, therefore, really a large reverberatory furnace, in which the volume of the articles to be fired is out of all proportion to the grate area of the fires.

The clay articles absorb a vast amount of heat at the beginning with very little apparent result, but the fuel consumption and the temperature increase as firing progresses.

The fuel required must contain small ash residue, and must be free from sulphur, giving a good flame. As was the case in all historical industries, wood was the fuel in early times. This explains many beautiful results of fire in bygone days. But although free from sulphur and other impurities, and most suitable, it had to be given up owing to its scarcity. Suitable coal has, so far, accomplished the firing process economically and satisfactorily, if only by the virtue of the fact that the stoking is intermittent. Sulphur is often found as sulphide of iron, accompanied by siliceous ash; it runs on the bars, gradually filling up the fire mouths, which, as already pointed out, have a limited grate area. The combustion of fuel is variable, and imperfect at the beginning, having mixtures of oxygen, nitrogen, carbon monoxide, carbon dioxide, and hydrocarbons, contaminated with the sulphur from the coal.

The construction and form of the fire of the kiln is such that it acts practically as a gas producer. Fresh fuel is carefully put on the front and top of the fire, allowing a mass of incandescent fuel to remain at the back to ignite the gases that may enter from the fuel in smoke or unconsumed gases. The fires are long, deep, and narrow. The average dimension is approximately 3 ft. 8 in. long, 1 ft. 8 in. wide, and 2 ft. 8 in. deep. Some of the early types had large and wide hobs, and the fuel was piled on these, so that nothing but the products of combustion could enter the firing chamber of the kiln.

Gas firing was tried in our works very many years ago. It worked very satisfactorily and economically in a confined furnace for glass making, but the firing of clay was not so successfully nor economically attained. In firing clay at certain stages, it is important that the heat, after being brought to a certain degree, should be maintained, neither allowing it to increase or decrease, so that the denser articles shall have absorbed the heat shown in the firing chamber throughout their cubical area. Only very large potteries could adopt gas economically, as often the case may occur that another oven or kiln may not be ready for the firing process, or that several kilns may require firing at the same time. In Staffordshire this is having considerable attention. Mond and other gases are being experimented with, and the results are awaited with deep interest. So far, the gas producer has been attached to each individual kiln, and no doubt as experience is gained in controlling the gas as we do with the coal fuel, similar results should be obtained with economy and cleanliness in working. So far the drawback has been in controlling the consumption of the gas in the firing chamber—a fierce heat obtains in one section, and none in another, so much so, that sometimes one end of a brick could be very hard, and the other not burnt through at all satisfactorily.

To get the full benefit of the gas produced, the producer requires to be in close proximity to the furnace using the gas, as the cooling of the gas from the producer to the furnace involves a loss of heat from the products of combustion. In order to make gas cheaply, production must not be intermittent. Storage would be required for a pipe system, and that would be a serious drawback. Difficulties would arise when the gas is stored through separation of tar, and consequent loss of a valuable heating constituent of the fuel. Leakage of pipes also would arise, and after all volatile sulphur compounds would remain. Nitrogen has no heating power, and in the most modern plants is extracted as sulphate of ammonia and sold as a fertilizer and as a valuable bye-product. In coal the hydrocarbons are at first driven off slowly, and as the temperature rises to redness, the carbonaceous matter begins to ignite, and to be effective in reducing the ferric oxides present in the clay to ferrous oxides; further, as the temperature increases, the oxygen entering with the burning of the fuel gives an oxidising reaction on the ferrous oxide. Iron is the chief colouring factor in clays, existing in several states of combination, and exercises, under certain circumstances, an injurious pyrometrical influence. It is not a mere question of the presence of one of these, but often two or more influence the colour. To demonstrate the effect of iron as a colouring agent, and the complex reactions of materials during firing, we may mention the thin, red Roman bricks, burnt right through, and completely oxidised. We have also the thicker bricks of to-day, varying from brown to orange, according to the firing of the kiln, and the dryness of the clay in the kiln. Then there are the plum-coloured Tudor bricks, fired with wood. The sickly yellow bricks, blanched by added chalk, made from London clay, are a good example of the curious effect of lime upon ferric oxide. But iron often combines with silica and small quantities of lime and alkalies, forming silicates and a vitreous mass apart from any colouring effects.

Therefore, the fired ware will be clean if the kiln atmosphere is light, and the draught so manipulated that it is sufficiently mixed with air—the firing will be of an oxidising nature. On the other hand, let the kiln atmosphere be slow and heavy, with little air, it is in a reducing condition of heat, and the clay, if it contains much iron, will be dark.

The regulation of the heat, and its distribution throughout the kiln from the circumference to the centre, and the bottom to the top, is the duty of the fireman. As already pointed out, the heat would naturally all ascend the "bags," as the fires are practically gas-producers, the fireman controls their action by the air-inlets and the dampers in the crown of the kiln.

Contraction, as a pyrometer, is the method generally adopted of testing the amount of work the heat is doing during the firing process. Contraction in firing is entirely a different matter to contraction in drying; it depends on the rate of heating. When the substances are brought to a given temperature slowly, the cubical contraction is always less than when they are rapidly heated, and the difference increases up to 1000° F.; at higher temperatures the difference generally decreases. Rapid firing has to be carefully guarded against, as the pressure is very great from outside the kiln, owing to the low pressure of

the atmosphere inside the kiln. The strength of the article is increased owing to contraction, as the fire proceeds; on the other hand, there is a marked diminution in measurement, or volume, without any essential alteration in weight, hence contraction can only be explained by the fact that the body possesses hollow spaces which, under the influence of heat, contract; this is fully determined by the actual porosity. Hence, the amount of porosity depends on the contraction of the clay, and is thus used as a test by the potter, who applies his tongue to the fired piece of ware to feel the quality and quantity of suction. Clay contains combined water, and shrinkage only begins after a temperature of 600° C. has been attained; to drive off the combined water, it may be treated as an amorphous body. Therefore, capillary forces must be at work as the temperature rises. This is the force which, in the case of rapid firing, shrinks the surface almost to vitrification, while the interior of the section is porous.

The smaller amount of water in the clay, the smaller is the resulting cubical contraction. Now, many articles are made of dry clay, in the form of dust, to obtain more exactitude.

In practice it has been found that clay with a large percentage of silica shrinks more during drying than firing, whilst with small proportions of silica, the contraction is greater during firing than drying. It has been found that vertical contraction is greater than horizontal contraction. Contraction formed the basis of Wedgwood's pyrometer. This consists of a number of half-baked pieces of clay, put into the kiln with the pottery, and taken out one by one, till the necessary contraction of the clay is produced. This method is still relied on by many potters to control the firing.

This system denotes not so much that the correct temperature has been attained, but rather that the firing had been sufficiently high for a long enough period. These pieces of clay, when fired, are put into a graduated slot, and the further they travel to the smaller end, the greater is the contraction and, consequently, the heat.

These test objects serve to show the potter how the firing is progressing, and enable him to draw his conclusions regarding the condition of the ware in the kiln, which is of greater importance than a knowledge of the temperature prevailing at any particular time.

The chemical composition of clay is represented by the formula $Al_2O_3.2SiO_2.2H_2O$, but little is known regarding the cause of plasticity, notwithstanding the large amount of attention which has been given to the subject.

To-day, the potter, in producing white clay articles with some degree of certainty and regularity, makes a mixture of various substances.

Blue ball clay forms one of the chief constituents. It varies in composition and colour from yellowish-white to black. It is soft and plastic, and infusible when free from alkalis, iron, and other fluxes. It is very refractory, retaining its form at a high temperature of fully 3000° F., and is capable of containing a large percentage of free silica. This not only increases the whiteness of the ware, but also counteracts the tendency, shown by clays with an excess of alumina in their composition, to shrink too much and crack.

Black ball clay is of a similar quality; it owes its distinctive colour to the quantity of carbonaceous matter it contains, sometimes as much as 9 per cent. It burns whiter than blue ball clay, on account of the reduction of its sesquioxide of iron in the kiln by the reaction with its carbonaceous matter.

Cornish stone is another ingredient. It is a potash felspar, or orthoclase, which contains 3 per cent. to 8 per cent. potash. It is mainly from the decomposition of this that china clay is obtained. Stone is rich in potash, but china clay does not retain this, otherwise it would be useless, on account of its non-refractory nature. China clay is fat and plastic in various degrees, according to its richness in alumina; it is dry and chalky when rich in silica. This latter variety does not shrink so much. Alumina is a most valuable constituent of clay, and plays a decisive part in influencing its properties. It is not only in itself difficult to fuse, but it also increases the refractory nature of the silicates.

The free silica employed is flint, a heavy and somewhat impure quartz. It is a crystalline silica, containing minute percentages of Al_2O_3, CaO, and Fe_2O_3. It is calcined to change it into amorphous silica, becoming then easier to grind. Le Chatelier and Cramer investigated this calcining of flint, showing how at about 600° C. it expanded 10 per cent. This gives some reasons for "duntage" and expansion, especially in silica bricks. It is an indispensable ingredient, and endures the highest temperatures without alteration. The co-efficient of expansion of a "body" may be increased by adding flint, as clay has a very low co-efficient, whilst flint has a high one.

The plasticity of a clay is not a measure of its tensile strength. Too much clay is often as bad as too much flint or silica.

We therefore find physical structure and chemical composition for the potter are inseparable, and are not only in themselves important. Such refractory substances as SiO_2, Al_2O_3, Fe_2O_3, and CaO, when mixed intimately, are found to flux under the influence of comparatively very moderate heat. A furnace built with fire-brick and lime mortar will flux into a black glass mass with very moderate heat in a very short time.

To a potter a flux may not necessarily be a fusible body, but one which, when added to the other materials comprising the "body," increases their fusibility.

On account of these complex reactions which take place in firing, practical firing tests must be made, if only to add to the value of the chemical analysis. Seger felt that some systematic range of trials should be adopted, and made cones varying from 600° C. to very high temperatures.

But, after all, the best test has been found is to heat a portion of the clay that is being fired to a certain degree of vitrification. In practical working the form of the articles affects result as the clay may have a different volume in each case.

No law as to firing and quantities can thus be laid down. If two or more kilns be built, so far as one can see alike in every respect, no two of them will fire in the same way. For the potter the pyrometer must be possessed not only of reliability and to give constant records, but the personal factor in manipulating should have no effect on its accuracy.

Sydney Section.

Meeting held at Sydney, on Wednesday, May 9th, 1906.

PROFESSOR A. LIVERSIDGE, F.R.S., IN THE CHAIR.

THE ESTIMATION OF TANTALUM BY MARIGNAC'S METHOD.

BY ARTHUR TIGHE.

In an attempt to estimate tantalum as the pentoxide by Marignac's method, considerable difficulty was experienced in obtaining the crystals of the double fluoride (K_2TaF_7). In all the text books consulted, it is directed, after dissolving the mixed oxides of tantalum and niobium, to add a quantity of acid potassium fluoride equal to one-quarter of the weight of the mixed oxides. But on concentrating to about 7 c.c., and cooling, I found that the crystals of the double fluoride did not appear, or only sparingly so, until a further quantity of acid potassium fluoride had been added, the best results being obtained with an amount equal to twice the weight of the ore taken for the assay. The proportions specified in the text books are evidently erroneous.

I also found that when the mixed oxides were dried in an air-oven, they became almost insoluble in aqueous hydrofluoric acid, although if transferred at once, without drying, they were readily soluble. It is, therefore, necessary to determine their weight by a separate experiment.

Obituary.

THOMAS ROYLE.

Thomas Royle was born in Salford in 1837, and was brought up at Crayford, in Kent. When thirteen years of age, he entered the works of the Swaisland Printing Co., and there worked his way up to the position of manager. He subsequently studied at the Royal School of Mines under Prof. A. W. Hofmann, and took first-class certificates. After a year or two as a calico printer at Foot's Cray, Kent, he entered the colour works at Greenford Green, founded by Dr. W. H. Perkin, and, later on, became manager of Burt, Boulton, and Haywood's colour works at Silvertown, where he remained some thirteen years. He then went to America, and built the works of the Mead Phosphate Co. at Charleston, S.C., but soon returned to this country, and became manager of Hardman and Holden's tar distillery, near Manchester. He also erected cyanide works in Germany, and works at Riga for Agthe, Fey, and Co. He was a chemical engineer of exceptional capacity, ability, and experience. Thos. Royle was an original member of this Society, and served on the Council; he was also a Fellow of the Chemical Society and of the Institute of Chemistry. He died on June 2nd, leaving a widow, four sons, and two daughters.

Journal and Patent Literature.

ENGLISH PATENTS.

Kilns; Impts. in tunnel ——. A. A. Gery, Reading, Pa., U.S.A. Eng. Pat. 12,874, June 21, 1905.

SEE Fr. Pat. 356,838 of 1905; this J., 1906, 21.—T. F. B.

Vacua; New method of producing ——. F. Soddy, Glasgow. Eng. Pat. 17,933, Sept. 5, 1905.

A RECEPTACLE containing metallic calcium is placed in communication with the vessel to be exhausted, and is provided with means for placing it in communication also with a supply of a gas (oxygen, hydrogen, carbon dioxide, &c.) capable of being completely absorbed by heated metallic calcium. The air is first pumped out by a mechanical or other exhauster, and a current of oxygen or other gas passed through to expel the residual air. The pump is then started again, and afterwards the metallic calcium is heated, when it absorbs all remaining gas.—A. S.

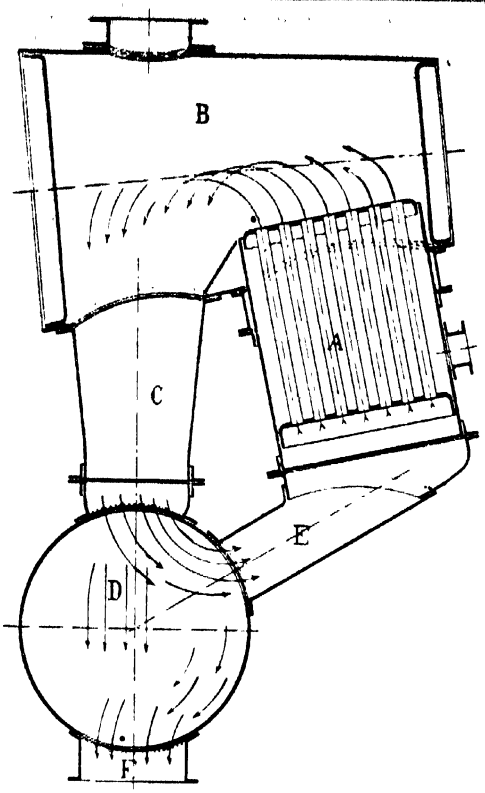
Vacua; Impts. in the production of ——. F. Soddy, Glasgow. Eng. Pat. 5349, March 5, 1906. (See preceding abstract.)

METALLIC barium or strontium may be used in place of calcium for absorbing the residual gases.—C. S.

Filters; Centrifugal ——. L. C. Trent, Van Trent, Cal., U.S.A. Eng. Pat. 20,866, Oct. 14, 1905.

SEE U.S. Pat. 806,213 of 1905; this J., 1906, 7.—T. F. B.

Filters; Impts. in ——. A. J. Boult, London. From E. Goldman & Co., Chicago. Eng. Pat. 2991, Feb. 7, 1906.



THE filter is composed of two or more superposed vertical cylindrical casings, each containing a number of superposed filter cells. The casings rest upon a base between two pillars, connected at the top above the filters by a movable cross-piece, which carries a screw. The latter serves to apply pressure to a cover or top piece, which rests on the upper filter casing; the whole series of filters is consequently pressed between the top piece and the base. The liquid to be filtered enters the casing at the bottom, and passes through the cells to a central pipe, which has an outlet at the bottom of each casing. By an arrangement of flexible connections the filters may be worked in series or in parallel.—W. H. C.

Filters; Impts. in ——. A. J. Boult, London. From E. Goldman & Co., Chicago. Eng. Pat. 2992, Feb. 7, 1906.

THE invention relates to filters, which consist of a number of superposed cells enclosed in a vertical casing, and held together by pressure applied by a screw from a cross-bar above (see preceding abstract). The cross-bar and the upper half of the casing are made to swing out sideways in order to facilitate the removal of the cells. The gasket joint between the upper and lower halves of the casing can be broken by means of a cam worked by a lever.—W. H. C.

Boiling apparatus for liquids containing or depositing solid substances. O. Faller, Basel, Switzerland. Eng. Pat. 24,737, Nov. 29, 1905.

THE claim is for improvements in apparatus described in Eng. Pats. 463 of 1872, 9499 of 1892 (this J., 1893, 510), 8763 of 1900 (this J., 1901, 460), and 20,147 of 1902 (this J., 1903, 202). The improved apparatus consists of a tubular heater, A, a vapour-separating chamber, B, and a solids-depositing chamber, D, connected as shown by the tubes, C and E. The tubes of the heater, A, are slightly inclined, to prevent solid matter from accumulating on the sides, and the heating jacket projects into the chamber, B, so that the liquid in the upper ends of the tubes is not cooled by contact with the body of liquid in B, which would tend to cause the choking up of the tubes by the deposition of solid matter. In consequence of the circulation of the liquid in the direction indicated by the arrows, the separated solids are carried forward, and settle in that part of the vessel, B, which is over the tube, C, and instead of falling back upon the tubes of the heater, A, and choking them, they are carried down the tube, C, into the vessel, D, where they accumulate. From time to time they are removed through the door, F, and the liquid returns to

the heater through the tube, E. Claim is also made for a double construction in which there are two heaters. —W. H. C.

Evaporating liquids; Apparatus for ——. D. Grove, Charlottenburg, Germany. Eng. Pat. 25,552, Dec. 8, 1905.

See Fr. Pat. 360,618 of 1905; this J., 1906, 462.—T. F. B.

United States Patents.

Dryer. A. T. Collins, Swarthmore, Pa. U.S. Pat. 823,262, June 12, 1906.

The material to be treated is made to travel along a jacketed trough by a conveyor formed of disconnected blades mounted on a shaft, which passes axially through the trough. Each of the blades has a scraper attached to it by a bolt at one end, so that the scraper falls by gravity, follows the contour of the trough, and removes and pushes forward any material which escapes the action of the blades themselves.—W. H. C.

Centrifugal machine. F. Kaehl, Berlin. U.S. Pat. 823,948, June 19, 1906.

See Ger. Pat. 155,562 of 1903; this J., 1905, 629.—T. F. B.

French Patents.

Separation of vapours of volatile liquids diffused or contained in air; Dynamo-thermal process of ——. A. Barbezat. Fr. Pat. 361,389, April 17, 1905.

The principle of the process consists in compressing the air containing the vapour to be separated, in a rotary compressor, and then, after passing it through a pressure-equalising vessel, allowing it to expand in a turbine, where it performs work. The air is cooled by the expansion, and the vapour is condensed, and collects in a peripheral chamber surrounding the turbine, the collection being assisted by the centrifugal force developed.—W. H. C.

Drying pulverulent and other materials; Process and apparatus for ——. J. Savary. Fr. Pat. 362,315, Jan. 10, 1906.

The material is first passed through a jacketed preheater and then through the dryer proper, the inlet and outlet openings of which are provided with double slides or doors to prevent the entrance of air. The dryer has hollow heating shelves provided on the inside with gills or blades, and over which the material is moved by rakes; the shelves are heated by injecting into them the steam or vapour given off from the material on them, after it has been superheated. For this purpose the steam is withdrawn from the dryer, and passed through a compressor to increase its temperature before returning it to the hollow shelves. The condensed liquid from the hollow shelves is passed through the jacket of the preheater in order to utilise the heat in raising the temperature of the material before it reaches the dryer proper.—W. H. C.

Dryer for animal or vegetable materials. E. Stauber. Fr. Pat. 362,477, Jan. 17, 1906.

The invention relates to a drying drum, which is rotated between a furnace and a chimney, the material to be dried being fed in at the chimney end, and carried forward to the outlet, near the furnace end, by an Archimedian screw. The furnace gases travel in the opposite direction, and dry the material, which leaves the drum by a number of holes pierced in the side of the drum just before it enters the furnace casing. The invention claimed consists in turning inwards the edges of the outlet end of the drum, and carrying them backwards into the interior in the shape of an open-ended funnel, which extends so far that it covers the outlets, and protects the dried material from the fire. It further serves the purpose of imparting a whirling motion to the furnace gases.—W. H. C.

German Patents.

Evaporation of liquids in a vacuum; Apparatus for the ——. E. Passburg. Ger. Pat. 166,045, Dec. 10, 1903. Addition to Ger. Pat. 162,237, Aug. 28, 1903.

The patent relates to apparatus of the type in which a heating drum rotates in the chamber containing the liquid to be evaporated, whereby a thin film of the liquid is produced on the surface of the drum. In order to prevent the liquid coming in contact with the ends of the drum, these are furnished with protective outer walls; and to prevent oil from the stuffing-boxes on the central shaft being drawn into the evaporating chamber, special oil-collectors are provided.—A. S.

Filtering drum with endless filter cloth. W. Guenther. Ger. Pat. 166,354, Sept. 13, 1904.

In ordinary drum-filters with endless filtering cloths, either the drum must be removed from the containing box, or the end of the box must be removed, in order to put the filter-cloth in place. According to the present invention, the filter-cloth is introduced through an annular slit in the end of the containing-box, and a "closing-ring" is provided for closing the slit.—A. S.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 634.)

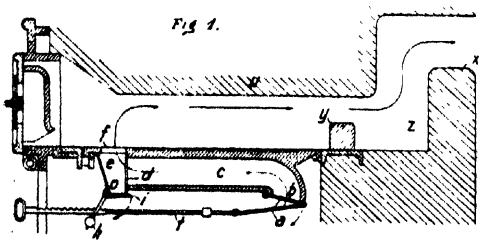
Suction gas producers for bituminous and small-sized fuel. C. Diegel. Stahl u. Eisen, 1906, **26**, 796—799.

The body of the producer for bituminous fuels consists of a circular brickwork casing, which at the top and at a point about one-fifth of the way down is built inwards so as to form circular ledges to support iron tubes. The upper and narrower of these tubes forms the feed, and can be closed at the top by a lid; its open lower end projects

a little way into the top of the wider tube, which is open at both ends, and the bottom of which reaches about half-way down the producer. It will thus be seen that when the producer is filled, the fuel in the bottom portion reaches the walls, but is surrounded, in the middle and upper portions, by two annular spaces which do not communicate with one another. The hot gases from the bottom bed of fuel rise into the lower annular space, and are thence taken off by a pipe to the engine. Their heat carbonises the fuel in the iron tube, and the gases and tarry vapours produced, rise into the upper annular space, whence they are taken off by a pipe to the bottom of the producer, and by means of a steam jet are driven with the air into the bed of fuel at the bottom. The fuel in the bottom section of the producer is thus always coke, and the gases taken to the engine are quite free from tarry and other condensable products. The gases pass, on their way to the engine, through a cooler, a scrubber, and a purifier, and the steam for the steam-jet is derived from the evaporation of water in the pipes of the cooler.

The producer for small fuel is rectangular, and has "stair-grates" along the bottom of two opposite sides, with hoppers for fuel above each. An inverted V of brickwork, parallel with the hearths, and a little above the middle height of the producer, shelters the exit pipe, which starts from the angle of the V, and ensures an open space free from fuel below it. The air passes from the grates (which from their form cannot be choked by the fuel) through the fuel to this central space, and the gases are thence drawn off as usual.—J. T. D.

Gas analysis; Sodium hyposulphite [hydrosulphite] in ——. H. Franzen. XXIII., page 715.



ENGLISH PATENTS.

Power and heat from highly explosive substances; Impts. in developing ——, *and in apparatus therefor.* J. de Dios, Tejada, New York. Eng. Pat. 22,125, Oct. 30, 1905.

THE explosive is exploded in a series of small charges in a detonating chamber. A portion of the resulting gases is used to operate the charging and detonating mechanism, and the remainder is either utilised directly for producing power and heat in separate apparatus, or it may be stored in reservoirs for future use.—W. H. C.

Smoke-consuming furnaces; Impts. in ——. J. O Schmidt, Mönchswalde, Saxony. Eng. Pat. 25,454 Dec. 7, 1905.

Fig 1.

THE air enters the hollow bars, *c*, through the opening, *b*, provided with the regulating door, *a*, common to all the bars, and operated by the rod, *t*. The air, warmed by its passage through the hollow bar, *c*, passes through the opening, *d*, into the ash-pit, *e*, which has an opening, *o*, closed by the door, *i*, kept in position by the counter-weight, *h*, and through which the ashes are removed. From the ash-pit, *e*, the air passes through the opening, *f*, into the furnace, where it is caused to pass close to the bed of fuel by the low furnace crown, *u*. A further thorough mixing and combustion of the gases takes place in the combustion chamber, *z*, formed by the two bridges, *x* and *y*, at the rear of the furnace.—W. H. C.

Gas producers; Apparatus for feeding and smoothing the fuel in ——. L. Weaselsky, Dresden, Saxony. Eng. Pat. 20,445, Oct. 10, 1905.

SEE Addition of July 11, 1905, to Fr. Pat. 335,291 of 1903; this J., 1906, 116.—T. F. B.

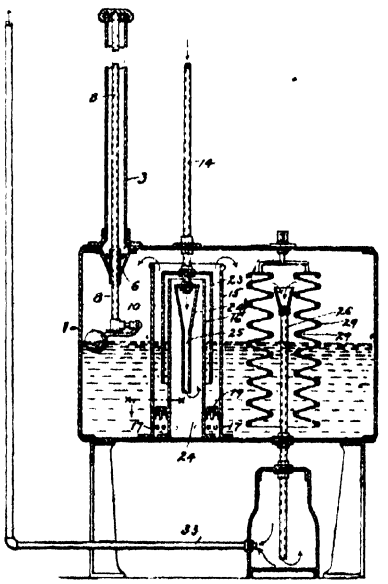
Gaseous mixture; Method of and apparatus for producing a combustible ——. C. K. Harding, Chicago. Eng. Pat. 21,369, Oct. 20, 1905.

SEE U.S. Pat. 803,534 of 1905; this J., 1906, 170.—T. F. B.

Acetylene gas; Purification of ——. G. F. Jaubert, Paris. Eng. Pat. 24,418, Nov. 25, 1905. Under Int. Conv., Nov. 28, 1904.

SEE Fr. Pat. 350,356 of 1904; this J., 1906, 116.—T. F. B.

Gases; Impts. in the cleansing of ——. H. N. Potter, New York. Eng. Pat. 12,210, May 25, 1906. Under Int. Conv., June 10, 1905.



THE gases are freed from dust and suspended particles by passing them through a porous screen coated with silicon monoxide powder. (See Eng. Pat. 26,788 of 1905; this J., 1906, 434.)—C. S.

UNITED STATES PATENTS.

Coke briquettes; Process for the manufacture of ——. L. L. D. Zuiderhoek, Amsterdam. U.S. Pat. 824,680, June 26, 1906.

SEE Eng. Pat. 17,906 of 1904; this J., 1905, 836.—T. F. B.

Carburetter. A. Akeson, Assignor to Standard Gas and Heating Co., Worcester, Mass. U.S. Pat. 823,382, June 12, 1906.

THE apparatus consists of a containing vessel, 1, supplied with the carburetting liquid through the pipe, 8, which passes through the vent pipe, 3, and is provided with a float-valve, 10, to maintain a constant level of liquid in the container, 1. The air to be carburetted enters by the pipe, 14, and travels in the direction indicated by the arrows through the carburetter, which is formed of a number of concentric cylinders, 15, 16, 23, and a conical pipe, 24, 25. The liquid enters the carburetter from the container through the perforations, 17, and the valves, 19, and the carburetted air leaves the vessel, 1, by the pipe, 26, surrounded by the collapsible bag, 29, and by way of the pipe, 33.—W. H. C.

Gas-generating furnace. C. A. Buzzell, Newburyport, Mass. U.S. Pat. 824,337, June 26, 1906.

THE gas-generating furnace comprises a furnace body provided with a steam-generating chamber, and enclosed in a gas-jacket. The fire-chamber is interior, and provided with a bottom fuel-grate, below which is a combined ash-pit and gas mixing-chamber with gas-tight closures. Between the fire-chamber and the enveloping gas-jacket is a space forming a water-jacket, which opens at the top into the steam-chamber. Steam is delivered, under pressure, into the fire-chamber above the fire-line, and passes through the fuel-bed and grate into the gas mixing-chamber. An oil-feed pipe extends through the fire-chamber, and is provided with a delivery port beneath the grate, where oil in gaseous form is delivered. The gas mixing-chamber is provided with gas-ports in communication with the gas-circulating jacket.—W. C. H.

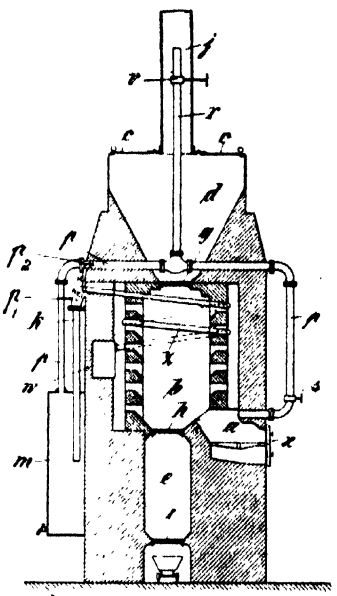
Gas-producer. H. Gerdes, Berlin, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 824,353, June 26, 1906.

THE fuel-chamber is formed by a casing, and a hearth extends beneath the chamber. Standards are arranged on the hearth on opposite sides of the casing, and guide-flanges on the standards. The ends of series of horizontal plates, arranged in different planes above the hearth, and on opposite sides of the centre of it, rest upon the guide-flanges. These plates form a stepped support for the fuel within the chamber, from the centre to the walls of the casing, with laterally-extending air-passages between the steps.—W. C. H.

Gas-producer; Suction ——. E. Higgins, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 824,358, June 26, 1906.

THE producer described consists of a casing having a "fire-lining" enclosing a combustion chamber, a grate of basket form in the lower portion of the chamber, and an ash-pit chamber beneath the grate, extending diametrically across the producer, through the lining to the walls of the casing. There is a horizontal air inlet passage into the casing, which opens into a horizontal semi-annular air passage, this passage being formed by a segmental baffle-plate, forming a portion of the supporting wall for the lining. The air enters by the central horizontal inlet, and passes both ways, through the semi-annular passage into the opposite ends of the ash-pit.—W. C. H.

Gas-producer. R. Hilprecht, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 824,359, June 26, 1906.



THE suction gas-producer described consists of an outer casing, and an inner casing tapered downwards, and open at its lower end, the space between the two forming an annular fuel chamber. The grate is arranged below the opening of the inner casing. The gas generated is withdrawn from the gas chamber within the inner casing through a suitable outlet pipe. A vaporiser is arranged in the upper portion of the inner casing, the conical or tapered hood of which forms a shoot down which fuel passes to the fuel chamber, from a hopper above the hood. Gases from the vaporiser and from the fuel chamber can be mixed, and conducted by a pipe to the ash-pit chamber below the grate.—W. C. H.

Gas-producer. E. Sandner, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 824,384, June 26, 1906.

A HOLLOW member passes transversely across the fuel chamber of the producer, the outer walls of this member being of inverted V-shaped cross-section, and the inner wall of cylindrical cross-section, and opening centrally downwards into the mass of fuel, thus forming an eduction conduit through which the generated gases are drawn. The space between the walls of this hollow member forms a water chamber, in which vapour is generated and commingled with the air drawn through the casing. The top of the vaporiser is provided with a detachable cap.—W. C. H.

FRENCH PATENTS.

Retort-oven for the carbonisation of peat, wood, &c., with return of the gas given off into the furnace. E. Stauber. Fr. Pat. 362,497, Jan. 18, 1906.

THE apparatus consists of a furnace, *a*, with a door, *x*, by which the supply of air is regulated, a carbonising chamber, *b*, above which is a chamber, *d*, where the peat undergoes a preliminary drying, and a cooling chamber, *c*, for the carbonised residue. The peat is charged into the drier, *d*, through the hinged doors, *c*, and its passage into the chambers, *b*, and *c*, is regulated by the slides, *g*, and *h*. From the cooler, *c*, the residue falls into trucks through the opening closed by the slide, *i*. The products of distillation pass by the pipe, *k*, to the condenser, *m*, and the uncondensed vapours and gases pass on by the pipe, *p*, into the furnace, any excess going directly to the chimney, *j*, by the branch, *r*. The quantity passing in either direction is regulated by the valves, *s*, and *v*. A tank, *w*, fed with water from without, is built into the brickwork, and communicates with the coil, *z*, in which steam is generated and superheated by the heat of the carbonising chamber, and then delivered by the valved pipes, p_1, and p_2, into the gas-pipes, *k*, and *p*, to cause an increased circulation of the gases.—W. H. C.

Gas-producer. P. M. V. Guignard, Fr. Pat. 361,331, April 6, 1905.

THE claim is for a producer with an open, easily detachable, water-jacketed bottom piece, from which the clinker can be easily removed. The water-jacket serves to cool the bottom piece, and to produce steam for use in the producer. The bottom piece has an inner ring, on which the fuel rests, screwed into it by a square-threaded screw, which presents a large contact surface between the ring and the bottom piece so that the heat is readily conducted away from the ring. The gas leaves the producer near the top, and passes first through a dust-separating chamber, and then through a water seal into a coke scrubber down which water is caused to flow. The producer proper is supported on one side by the washer, and on the other by a leg bolted on to it, leaving the space below free, so that access can be easily had to the bottom for clinkering. —W. H. C.

Gas generator. Kynoch, Ltd. Fr. Pat. 362,436, Jan. 16, 1906.

SEE Eng. Pat. 13,517 of 1904; this J., 1905, 666.—T. F. B.

Oxygen; Production of ——, for use in combustion motors. P. Winand. Fr. Pat. 362,524, Jan. 19, 1906. Under Int. Conv., Feb. 9 and 16, 1905.

See Eng. Pat. 3121 of 1906; this J., 1906, 632.—T. F. B.

Incandescence by gas, obtained by the application of artificial threads in the form of hydrated refractory oxides to moist atmospheres; New process of ——. A. M. Plaissetty. Second Addition, dated Jan. 9, 1906, to Fr. Pat. 321,803, May 2, 1902. (See this J., 1903, 291 and 547.)

This addition to the original patent covers the use for incandescence mantles of threads of cellulose or its direct derivatives in the form of homogeneous filaments that have lost their natural cellular structure, obtained by solution of cellulose or of its substituted derivatives in an appropriate solvent.—W. C. H.

German Patent.

Gases; Process of and apparatus for filtering ——. H. Apel. Ger. Pat. 166,614, May 4, 1905. Addition to Ger. Pat. 166,613, Nov. 22, 1904.

The gas before being passed through the series of filtering layers described in Ger. Pat. 166,613 (this J., 1906, 633), is conducted through a water-separator of the ordinary kind, provided with baffle-plates to form a zig-zag path for the gas. The spaces between the baffle-plates may be filled with "wood-wool."—A. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 634.)

Ammonia as a by-product in coke-making; Use of gypsum for the recovery of ——. H. Warth. Chem. News, 1906, **93**, 259—260.

In places where large quantities of sulphuric acid are not available, the author recommends the use of calcium sulphate for the recovery of ammonia from gas-liquor. A sample of gas-liquor containing 2·6 grms. of ammonia per 100 c.c. was well shaken with plaster of Paris, allowed to settle, and the clear liquid drawn off. From the clear solution it was found possible to recover 97 per cent. of the ammonia present in the original gas-liquor, *viz.*, 17 per cent. by boiling the solution, and absorbing the evolved ammonia in sulphuric acid, and 80 per cent. by concentrating the residual solution to obtain crystallised ammonium sulphate. If it were desired to dispense altogether with the use of sulphuric acid, the gas-liquor might be first treated with calcium sulphate, the solution drawn off and treated with ferrous sulphate, the precipitated ferrous sulphide removed, and the clear solution evaporated to obtain crystallised ammonium sulphate. It was found possible in this way to recover 95·4 per cent. of the total ammonia.—A. S.

Wood distillation in the United States; Census of ——. Oil, Paint, and Drug Rep., July 2, 1906. [T.R.]

The Director of the Census has announced the result of the tabulation of the statistics for wood distillation for the calendar year 1904, forming a part of the census of manufactures of 1905. Following is a summary of the report:—

The statistics for the 141 establishments engaged in this industry are summarised in the following statement:—

Capital	$10,506,979
Materials used—	
Total cost	$4,847,770
Wood—	
Cords	586,144
Cost	$1,783,004
Lime—	
Bushels	523,334
Cost	$101,068
Soda—	
Pounds	371,780
Cost	$5,484
Crude wood alcohol—	
Gallons	5,723,001
Cost	$1,976,156
Smoke, cost	$22,998
All other materials, cost	$959,070
*Products, total value	$7,813,483
Wood alcohol, crude—	
Gallons	6,684,871
Value	$2,161,813
Refined—	
Gallons	4,316,346
Value	$2,618,886
Acetate of lime—	
Pounds	105,141,361
Value	$1,474,982
Charcoal—	
Bushels	25,869,055
Value	$1,197,973
All other products, value	$364,829

*Exclusive of wood distillation products valued at $1,208,335, made in establishments engaged primarily in the manufacture of other products. The principal items included in this amount are:—Crude alcohol, 129,387 galls., valued at $40,148; refined alcohol, 1,585,807 galls., valued at $824,239, and charcoal, 6,045,157 bushels, valued at $290,192.

Petroleum of good quality; Attempts to obtain ——, without chemical refining. K. Charitschkow. Westnik shirow. promysl., 1906, **7**, 61. Chem.-Zeit., 1906, **30**, Rep., 205.

On repeating the treatment recommended by Deichler (Ger. Pat. 160,717 of 1904; this J., 1905, 1295), namely, warming the crude oil for some time in presence of 1 per cent. of metallic sodium, and then distilling under a reflux condenser, the author collected two fractions, one coming over below 150° C., the other (lamp oil) between 150° and 270° C. In colour they were equal to the ordinary refined products, but the light fraction had a more pungent smell. In point of acidity, the use of sodium made little difference to the light fraction, but considerably reduced that of the lamp oil. It is concluded that, though the method is capable of economising caustic soda in refining, the acid process is still necessary, and the advantages are diminished by the higher consumption of fuel required in the preliminary heating process.—C. S.

French Patents.

Decomposition of the products of distillation during carbonisation, Process for avoiding ——. H. Koppers. Fr. Pat. 362,505, Jan. 18, 1906.

A current of inert gas, that is, a gas which has no chemical influence on the reactions taking place in the coking chamber, is introduced above the charge for the purpose of hastening the removal from the chamber of those products which may become modified by prolonged contact with the heated interior. It is preferred to use for this purpose a portion of the coke-oven gases themselves after they have been cooled and purified. In addition to the above action, the introduction of cool gases into the oven keeps down the temperature of the space above the charge. If desired, a gas or vapour which acts chemically on the charge may be introduced along with the inert gas.—W. H. C.

Coal and other substances; Distillation of ——, and apparatus therefor. J. Bowing. Fr. Pat. 362,506, Jan. 18, 1906.

See Eng. Pat. 580 of 1905; this J., 1906, 171.—T. F. B.

Acetone; Industrial manufacture of ——. Soc. Pagès, Camus, et Cie. Fr. Pat. 361,379, April 14, 1905.

See Eng. Pat. 8757 of 1906; this J., 1906, 634.—T. F. B.

Mineral oils and similar substances; Process for preparing emulsions of heavy ——. J. P. Van der Ploeg. Fr. Pat. 361,395, April 19, 1905.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 635.)

Nitrophenolsulphonic acids; Study of the ——. R. Gnehm and O. Knecht. J. prakt. Chem., 1906, **73**, 519—537.

Experiments were made to prepare sulphonic acids from *o*-, *m*-, and *p*-nitrophenols with the following results:—*o*-Nitrophenol with concentrated sulphuric acid or chlorosulphonic acid gives one sulphonic acid, $C_6H_3OH(NO_2).SO_3H$,1:2:4. If mercury be added to the reacting mixture, several sulphonic acids are produced, but only one of these, an *o*-nitrophenoltrisulphonic acid, was isolated in the form of its barium salt. *m*-Nitrophenol gives a sulphonic acid when acted on by sulphuric acid, but not by chlorosulphonic acid, and mercury accelerates the reaction. The position of the groups in this acid is not known. *p*-Nitrophenol gives with sulphuric acid, but not with chlorosulphonic acid, one sulphonic acid, $OH:SO_3H:NO_2$,1:2:4. The reaction is accelerated but not otherwise changed by addition of mercury or boric acid.

The greater readiness of *o*-nitrophenol to react with chlorosulphonic acid than *m*- and *p*-nitrophenol is explained by the directive influence of the two groups already attached to the benzene nucleus.—C. E. F.

Dyestuffs; New ——, *fixed by metallic oxide mordants.* Poirrier and Ehrmann. Bull. Soc. Ind. Mulhouse, 1906, **76**, 69—71.

On heating for an hour on the water-bath, dinitrosoresorcinol (8 parts) with resorcinol (30 parts) and hydrochloric acid (6 parts), a dyestuff is formed which dyes tissues mordanted with iron oxide, alumina, and chromic oxide, in yellowish-brown shades. Mononitrosoresorcinol (7 parts), similarly heated with aniline (10 parts) and hydrochloric acid (100 parts), yields a compound which dyes iron-mordanted tissues in greyish-blue, and alumina-mordanted tissues in blue shades. Mono- and dinitrosoresorcinol, when heated alone with hydrochloric acid, also give dyestuffs, of the same class, but deficient in dyeing power.

C. Vaucher, who has examined the above dyestuffs, along with one prepared by heating together nitroso-2.7-dihydroxynaphthalene, pyrogallol, and hydrochloric acid, finds that they possess a general similarity in character. They are insoluble in water, and easily soluble in alkalis. They all give yellowish-brown shades upon iron oxide, chromic oxide, and aluminium hydroxide mordants. When printed in ammoniacal solution, and steamed, they give brown colours which are inferior in intensity to that yielded by an ammoniacal solution of dinitroresorcinol (this J., 1899, 270).—E. B.

Colouring matters from molasses, vinasse, &c. Wichardt. Z. Ver. deutsch. Zuckerind., 1906, 595—596.

The author describes the manufacture of a dyestuff from ammonium molybdate and molasses, vinasse, &c. Ground ammonium molybdate, $(NH_4)_2MoO_4$, is dissolved in hot water, and molasses or vinasse is added to the solution in the proportion of 1 part of molasses to 10 parts of molybdate. After warming for a considerable time the solution becomes green. Addition of some dilute sulphuric acid causes the solution to become bluish-green, and with more acid, deep blue. The dyestuff may be precipitated by addition of spirit, and if excess of molybdate has not been used, the supernatant liquor may be poured off, and the residual dyestuff freed from sugar by washing with water. The purified substance is slowly dried on the filter, ground, and sifted. The product thus obtained is exactly similar to "mineral indigo," Mo_8O_7, and behaves towards acids and alkalis just like the latter. If the filtrate is treated with milk of lime, and again neutralised, the sugar may be recovered. The dyestuff may be used for dyeing linen, cotton, wool, and silk, as well as for the preparation of pigments, since it possesses great covering power, and is very stable.—L. E.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 636.)

"*Ecru*" *silk; Chemical characteristics of* ——. G. Gianoli. Report of the Milan Commission on Silk. Rev. Gén. des Mat. Col. 1906, **10**, 199—201.

Until recently, practical men attributed great importance to the colour, smell, and "handle," in order to judge if silk were pure, and in case of doubt they boiled off the silk in order to determine the percentage of fibroin present. However, the differences which are always met with in silks of the *Bombyx mori* of the same race or of the same cross even when cultivated in the same district, and the inequalities which depend on the culture, food, &c., do not permit an accurate judgment of the silk on the determination of the fibroïn alone, as this has been shown to vary from 73 to 84 per cent. Since the proportion of matter soluble in a soap solution may vary from 16 to 27 per cent., it is possible to increase artificially the proportion of "impurities" which is usually found

in the fibre, and this makes it necessary to establish limits between which this proportion can vary owing to natural causes. To show whether silks of known purity had chemical properties sufficiently characteristic, ten well-known samples were examined, with the following result:—

	Minimum.	Maximum	Mean.
Matter soluble in:	per cent.	per cent.	per cent.
3 per cent. soap solution ..	21·449	25·913	22·865
Distilled water at 50 —55° C.	0·447	1·053	0·617
Ether.....	0·104	0·451	0·275
Ash	0·726	1·903	0·853

The silks examined being from different Provinces, these limits were taken as standards of purity, and similar determinations with more than a hundred samples have confirmed the results. In order to show the effect of the extractive matter in the water used for unwinding the cocoons, experiments were made in winding Chinese cocoons in water which contained from 16—27·9 grms. of extractive matter (from the chrysalides, &c.), the variation being due to the condensation of steam.

The silk obtained, gave the following results, compared with the same silk wound with ordinary water:—

	Water containing extractives.	Ordinary water.
Loss on boiling off	22·63	18·85
Loss with water 50°—55° C	3·83	0·18
Ether extract	0·56	0·29
Ash	1·14	0·82

These figures show remarkable differences, due to the presence of extractive matter in the water used for unwinding. The following figures show the results obtained with various species of silk:—

Species.	Loss on washing.	Boiling off	Ether.	Ash.
White Kutais	0·57	22·16	0·55	0·83
White Turkestan	0·32	21·44	0·31	0·91
Yellow Adrianople	0·54	24·88	0·35	0·88
Yellow Greek	0·69	24·64	0·26	0·91
White Chinese crossed with yellow Italian	0 59	22·48	0·39	0·81

The slight variation in the figures, even with silks from very different places, is explained by the fact that the cocoons, during winding, &c., are treated with a relatively large quantity of warm water, which causes the differences due to the nature of the cocoons to disappear. The determination of the matter soluble in water at 50°—55° C. has become of great importance, indicating indirectly whether extractive matter, soap, glycerin, dextrin, glucose, borax, or other matters soluble in water have been added to the silk to increase its weight. In order to allow for differences in the water employed for winding, it has been decided by the International Congress that the amount soluble in water must not exceed 1·5 per cent. Owing to the difficulty in drying silk at 110°—120° C., the temperature employed in conditioning has been raised to 140° C. If the silk contain substances such as glycerin, some of these are vaporised with the water, and thus cause too high results to be obtained for the amount of water.

Another difficulty in the testing of silk is the "sampling." Cocoons from the same lot have given differences of 9 per cent. in the amount of fibroin present, and portions of the same silk have shown differences of 2·63 per cent.

In the Milan Laboratory the samples are placed in tubes of nickeled copper or aluminium, and heated air under pressure is passed through them. The tubes are closed, and allowed to cool in a desiccator before weighing. The silk is then plunged into ten times its weight of distilled water, heated to 50°—55° C. on a water-bath, and left for half an hour; the water is then changed, and the silk left for another half-hour at the same temperature. The fact that the loss may not exceed 1·5 does not show that the silk is pure, as the water only removes soluble substances. The silk should also be treated with ether, as the proportion of natural silk soluble in this solvent varies between well-defined limits.

The presence of inorganic adulterants can usually be found by an ash estimation, as the amount in a pure silk very seldom exceeds 1·0 per cent.—A. B. S.

Silk weighted with tin, and of good resistance to light Sealed Note No. 1377, Feb. 3, 1903. O. Meister. Also Report on same by E. Grandmougin. Bull. Soc. Ind. Mulhouse, 1906, 128—133.

SILK heavily weighted with phosphate and silicate of tin is liable to become tender on storing, especially if exposed to sunlight. The spontaneous formation of red spots, where both dyestuff and silk are destroyed, has also been frequently observed, and has occasioned very heavy losses to silk dyers. It has been established, in particular by the work of Sisley and of Gnehm respectively, that the spots are caused by the presence of sodium chloride, perhaps also by the presence of traces of copper (see O. Meister, Chem.-Zeit., 1905, 39). Precautions have consequently been taken, which have considerably diminished the frequency of this complaint. In his communication, O. Meister states that silk heavily weighted by the tin-silicate-phosphate process may be rendered completely immune from the formation of spots, and also from the liability to become tender on exposure to light, by treatment with a preparation of ammonium thiocyanate, glycerin, boric acid, and tannin. Thus, silk weft yarn weighted 100 per cent., and then after-treated was, it is stated, unaffected by exposure to bright sunlight for several months. The same silk not after-treated had considerably diminished in strength and elasticity after an exposure of only a few days. The process has been successfully employed since 1902 in a large silk dyehouse. Grandmougin points out the great importance of this work to the silk trade, especially in view of the approaching expiration of the agreement between the Zürich and Crefeld manufacturers. This agreement, by which the weighting of silk warp was limited to 20—30 per cent., and that of silk weft to 60—80 per cent., was not renewed at the Turin International Conference in 1905, the settlement of the question being referred to a special committee.—H. L.

Wool; Effect of chlorine on ——. L. Vignon and J. Mollard. Comptes rend., 1906, **142**, 1343—1345.

THE authors have examined the effect of chlorine, as gas, as chlorine water, and as bleaching powder, on wool when used to bleach it. They find that it modifies the wool, and may under certain conditions entirely destroy it. The wool loses up to 10 per cent. of its weight; the treated wool dyes more readily than the untreated, giving deeper and more brilliant shades. The elasticity and tenacity of the wool are usually diminished by the treatment, but the fibres still readily felt together, and the tendency to shrinkage is greatly lessened.—J. T. D.

"*Lappings*," *composed of woollen and cotton tissues, employed in tissue printing; Note on the manufacture of* ——. C. Rollin. Bull. Soc. Ind. Mulhouse, 1906, **76**, 59—62.

CERTAIN tissues employed in lapping the impression cylinders of printing machines for the purpose of giving the necessary elastic pressure to the tissues to be printed, as these pass between the cylinders and the printing rollers in the operation of printing, and made by fastening together by means of a solution of india-rubber a web of woollen tissue and one or more, usually two, webs of cotton ("cretonne") tissue, frequently, after being in use for a short time only, become unfit for further use owing to the cotton tissue on one or both sides of the woollen tissue becoming in parts detached from the latter. This occurrence is sometimes caused by the chemical action on the india-rubber of compounds present in the printing

mixtures employed. Sometimes it is due to mechanical causes. Of these, it is commonly assumed that bubbles of air left between the several layers of tissues in the process of preparing the "lapping," constitute a frequent source of the damage. The author, however, attributes it primarily to the different elasticities of wool and cotton, the tissues stretching to different extents under the pressure to which they are subjected in the printing operation. To prevent it from taking place, it is recommended that the woollen tissue should be stretched to some extent before attaching it to the cotton tissue or tissues, and that the "lapping" thus made should not be stretched more than is necessary when the impression cylinder is being wrapped with it.—E. B.

Nitrosamine Red [Paranitraniline Red]; Method of printing ——, in association with sulphur dyestuffs and indigo. C. Favre. Bull. Soc. Ind. Mulhouse, 1906, **76**, 67—68.

Sulphur dyestuffs and indigo may be printed in conjunction with Paranitraniline Red on tissues prepared in sodium β-naphtholate, but the latter cannot be kept long before printing. The necessity for preparing in β-naphthol is avoided by using for the red a mixture composed of "Nitrosamine Red" (this J., 1894, 2189), "β-Naphthol R," dissolved in the requisite quantity of caustic soda-lye, and sodium sulphoricinoleate (Turkey-red oil) with the addition of a small quantity of an easily decomposable salt, such as ammonium oxalate, the whole being thickened with gum tragacanth. The following are suitable proportions:—1·2 litres of a paste made from 360 grms. of "β-Naphthol R," 360 grms. of "caustic soda-lye," 0·4 litre of sodium sulphoricinoleate, and 2·4 litres of gum tragacanth paste (75 grms. per litre), are mixed with 2·4 litres of gum tragacanth paste, 60 grms. of ammonium oxalate, and 2·4 litres of a paste prepared by mixing 1 kilo. of "Nitrosamine Red" paste with 2 litres of gum tragacanth thickening. The ammonium oxalate may be omitted from the printing mixture, and applied to the tissue in the form of a preparation-solution (10 grms. per litre), double the proportion of caustic soda employed in the above mixture being in this case taken. After printing, the tissues are steamed for two minutes, soured, washed, and soaped.—E. B.

Wool; Printing —— with printing-mixtures containing phenol. E. Justin-Mueller. Bull. Soc. Ind. Mulhouse, 1906, **76**, 72—74.

Based on the observation that wool prepared for printing by treatment with chlorine, is more readily moistened by water than wool not so treated, endeavours were made to find a compound possessing the property of instantaneously moistening this fibre, with the object of enabling it to be printed in the unchlorinated condition, and thus to dispense with the operation of chlorinating. Phenol, ethyl alcohol, and Turkey-red oil were found to have, in different degrees, the desired property, the first acting the best. An addition of 30 grms. of phenol per litre of the printing-mixture suffices in most cases to give, upon unprepared woollen tissues, colours almost as intense as those produced upon prepared tissues with similar mixtures from which the phenol is absent. The effect is greater when the tissues, before printing, are treated with acid, *e.g.*, by boiling for half an hour in a bath containing 10 per cent. of their weight of sulphuric acid. In the printing of chlorinated tissues, the addition of phenol to the black and dark blue printing-mixtures serves to give well defined and regular impressions. The use of phenol is, moreover, very advantageous in the printing, by the Vigoureux method, of woollen slubbing, which it is impracticable to prepare with chlorine.

H. Grosheintz, who has been asked by the Mulhouse Industrial Society to report on the above paper, states that the printing-mixtures containing phenol, give on unchlorinated wool, shades only slightly deeper than those obtained with the mixtures in ordinary use, and much paler than those produced with the latter mixtures on chlorinated wool. Still there is no doubt that the moistening of the wool is greatly aided by the presence of the phenol. In regard to the treatment with sulphuric acid, Grosheintz's results do not entirely accord with the author's, but this matter is considered of little importance. Grosheintz adds that, without detracting in any way from the merit of the author's note (dated Aug. 13, 1903), which appears to be the first to be published relating to the subject, the firm of Scheurer, Lauth, and Co. in 1897 and for some time afterwards made use of phenol in some of their printing-mixtures for wool. The addition was not made to all the mixtures, as it was found that the phenol had a harmful influence on certain shades. The use of the compound was ultimately abandoned, as, owing to the presence of impurities in the product at first employed, an objectionable smell, which it was impossible to remove, was left in the tissues. The use of pure phenol, it is stated, is unattended by this drawback.—E. B.

α-Naphthylamine Claret; Discharging of ——, by means of [hydrosulphite-][sulphoxylate-]formaldehyde in the absence of iron salts. L. Baumann and G. Thesmar. Z. Farben-Ind., 1906, **5**, 221—223.

In a sealed communication to the Soc. Ind. de Mulhouse, No. 1559, dated August 25, 1905, the authors, together with Hug, described a method of producing coloured discharges on α-Napthylamine Claret with hydrosulphite-[sulphoxylate-]formaldehyde without the addition of iron salts. The principle consists in increasing the acidity of the sulphoxylate-formaldehyde preparation at the moment of reaction, viz., during steaming. Acids cannot be directly added to the printing-mixture, as they decompose sulphoxylate-formaldehyde, and the object is attained by adding a volatile organic base in conjunction with an organic acid or organic acid ester. Of all the organic bases tried, o-anisidine yields the best results. Mono-methylaniline and o-toluidine are also good; aniline and ordinary toluidine have a weaker action. Xylidine and cumidine being less volatile, are also unsatisfactory, unless the goods are subjected to repeated steaming. The best organic acids or derivatives thereof are, in the order of efficiency, levulinic acid, methyl and ethyl tartrate, oxalic, citric, benzoic, salicylic, lactic, succinic, phthalic, and gallic acids. Examples of printing-mixtures which yield a good white discharge are given in the following table:—

400	400	400	400	350	400	Starch-tragacanth thickening solution.
400	400	400	400	350	400	Rongalite C.
30	30	30	30	30	30	Sodium ricinoleate.
–	160	–	–	–	–	o-Anisidine.
80	–	–	–	–	–	Mono-methylaniline.
–	–	160	125	150	125	o-Toluidine.
–	–	–	30	–	30	Dimethylaniline.
120	–	–	–	–	–	Levulinic acid, 25 per cent.
–	10	10	15	–	–	Methyl tartrate, 22° B.
–	–	–	–	120	–	Benzoic acid.
–	–	–	–	–	15	Citric acid.
1000						

After printing, the goods are thoroughly dried, steamed—if necessary repeatedly—for four minutes in the small Mather-Platt, rinsed, soaped, and dried. Most ingrain dyeings can be discharged white in this way.

Printing-mixtures for coloured discharges are readily prepared by dissolving basic dyestuffs in the aromatic base, and tannin in the thickening solution. Gallocyanine dyestuffs may also be used with or without the addition of a mordant. The goods are passed through a weak bichromate solution, rinsed, soaped in the presence of tartar emetic, again rinsed, and dried.

With regard to the comparative advantages of the old ferric-citrate-nitrite process (see this J., 1906, 371) and the above, the authors state that the former is still exclusively employed by them in practice, although the iron salt affects the shade of certain basic, particularly yellow basic, dyestuffs. The new process is free from this disadvantage, and yields satisfactory results for coloured discharges. On the other hand, the printing-mixtures are liable to run, owing to the large quantity of aromatic base that is required; and consequently the white produced on light printing cloths is liable to be

blurred and indistinct. Thus, a satisfactory white can only be produced by the new process on heavier cloths, such as sateens. This difficulty in obtaining a good white in conjunction with coloured discharges renders the new process practically inferior to the older one.

—H. L.

α-Naphthylamine Claret; Improved methods of producing white and coloured discharges upon —— [*with the aid of Setopaline and Alizarin Orange*]. P. Wilhelm. Bull. Soc. Ind. Mulhouse, **76**, 1906, 84—93.

With "dry hydrosulphite" (*hyposulphite*).—"Dry hydrosulphite" (B.A.S.F.), employed in a neutral medium, *e.g.*, in the presence of dextrin and glycerin, gives an imperfect discharge on tissues dyed in α-Naphthylamine Claret. Discharges are, however, readily obtained when certain basic dyestuffs are added to the mixture. Thus, a *blue discharge* is produced with a mixture of "dry hydrosulphite" (300 parts), ground to a smooth paste with glycerin (150 parts), the paste being poured into a solution of dextrin (125 parts) in glycerin (125 parts) and water (50 parts), to which, are added, first, a solution of Thionine Blue (30 parts) or Discharge Navy Blue S (M.L.B.) in phenol (75 parts), and then a solution of tannic acid (75 parts) in glycerin (75 parts). *Yellow, pink, and green discharges* are produced by substituting for the blue dyestuff in this mixture, Auramine, Rhodamine 6G, and a mixture of Auramine and Thionine Blue, respectively. For *a white discharge*, "dry hydrosulphite" made into a paste with glycerin (550 parts of a 66 per cent. paste) and thickened with dextrin (200 parts) and caustic soda-lye (250 parts at 40° B.) may be used. The tissues printed with these mixtures are steamed for four minutes, passed through a bath of tartar emetic, and soaped at full width. This method of discharging does not, however, give regular results. The coloured discharges lose their purity of shade as the printing proceeds. Further, the undissolved hydrosulphite present in the printing-mixtures scratches and damages the printing rollers.

Discharges with sodium hydrosulphite-(sulphoxylate-) formaldehyde.—When this is printed upon tissues dyed in α-Naphthylamine Claret, which are afterwards treated in the same manner as tissues dyed in Paranitraniline Red, a half discharge is produced upon the Claret with a mixture which is sufficiently concentrated to yield a complete discharge upon the Red. In the presence, however, of certain dyestuffs which appear to have a "catalytic" action, a perfect discharge of the Claret results. The dyestuffs which have been found to act most powerfully in this connection are Setopaline (Geigy and Co.) and nitro-alizarin. With each of these white discharges are readily obtained. While, however, to give good results, the nitro-alizarin requires an addition of caustic soda or caustic potash to be made to the printing-mixture, and the steam employed in the steaming operation to be as dry as possible, the Setopaline acts best in a slightly acid mixture and in the presence of glycerin, *i.e.*, a hygroscopic agent. Again, the best thickening for the nitro-alizarin mixture is gum, whilst that for the Setopaline mixture is gum tragacanth. The printing-mixtures are composed as follows:—("White A") Gum tragacanth paste (300 parts), Setopaline (10 parts) dissolved in phenol (40 parts), and glycerin (150 parts), which are mixed together, and heated to 56° C., at which temperature the "Hydrosulphite NF" (450 parts) is added, and dissolved. The function of the phenol in this mixture, it is explained, is probably that of a weak acid. "White B" consists of "Hydrosulphite NF" (500 parts) dissolved at 50° C. in gum solution (200 parts of a 33 per cent. solution) and water (60 parts). The solution is cooled to 31° C. before nitro-alizarin (70 parts of a 20 per cent. paste) is added, and completely cooled before a final addition of caustic potash-lye (200 parts at 50° B.) is made to it. "White B" is not adapted for printing in association with Aniline Black, the acid vapours disengaged from the printing-mixtures employed in producing the latter, neutralising the alkali in it, and preventing it from acting properly. For printing in conjunction with this colour, "White A," which is free from this defect, is used. "White B" may be prepared with "Hydrosulphite NF concentrated," half as much of this as of ordinary "Hydrosulphite NF" being taken. On the other hand, "White A" does not discharge so well with the "concentrated" as it does with the ordinary "Hydrosulphite NF." This is probably owing to the Setopaline becoming transformed by the former product into a compound devoid of "catalytic" action. The addition of an excess of tannic acid, however, keeps the dyestuff in an active condition. Advantage is taken of this in the preparation of coloured discharges. The "concentrated" preparation, moreover, gives better results than the ordinary preparation with certain dyestuffs; thus, with nitro-alizarin, in a neutral mixture, it gives a much better discharge than does the latter. Although the action is too incomplete for a white discharge to be produced in this manner, it may be utilised in effecting a yellow discharge by means of a mixture containing nitro-alizarin, Auramine, tannic acid, and glycerin, in addition to the "Hydrosulphite NF concentrated." Again, Rhodamine 6G, with the latter preparation, in the proportion of 4 grms. per litre of the printing-mixture, completely discharges the Claret. With proper proportions of this dyestuff, dark and pale pink discharges are readily produced. Acridine Yellow also exhibits a similar action, but in lesser degree. By extending the duration of steaming to six minutes, this dyestuff gives a yellow discharge with a greenish tone, which may be "corrected" by the addition to the printing-mixture of a minute proportion of Rhodamine 6G. With these two dyestuffs, the presence of glycerin in the mixtures is necessary. *Dark blue discharges* are obtained with Discharge Navy Blue S along with Setopaline, tannic acid, glycerin, and "Hydrosulphite NF concentrated." *Pale blue discharges* are effected with Thionine Blue and the same reagents. *Olives* and *greens* are produced from mixtures of these dyestuffs and Auramine. The tissues, after printing, are steamed for four to five minutes, then passed through a bath of tartar emetic, rinsed, and soaped for two minutes at 56° C. The pinks, after steaming, have a slightly purplish tint, which disappears on clearing with bleaching powder solution. All the discharge-mixtures keep well and print easily. It is essential for success that sodium ricinoleate ("soluble oil") should be added to the sodium β-naphtholate solution with which the tissues are prepared in the production of the Claret. If this be omitted, the discharge-mixtures, with the exception of "White B," yield unsatisfactory results. The printing-mixtures described, may also be employed in discharging the Puce from benzidine and β-naphthol.

F. Binder and C. Eckert, at the request of the Mulhouse Society, have repeated Wilhelm's experiments, and confirm his results. They state that a printing-mixture containing per kilo., 400 grms. of "Hydrosulphite NF" discharges Paranitraniline Red perfectly, but scarcely attacks Naphthylamine Claret and Benzidine Puce. The same mixture, with the addition of Setopaline, glycerin, and phenol, discharges both of the latter colours. Nitro-alizarin acts similarly to Setopaline, but the printing-mixtures containing it keep badly. They gradually disengage formaldehyde, and become useless for printing. Setopaline gives its full effect only in the presence of glycerin. Rhodamine 6G and Acridine Yellow act like Setopaline, but less powerfully, Acridine Yellow being the weakest in this respect. Binder and Eckert consider that Wilhelm's discovery possesses technical interest of the highest importance, and opens up a new method of producing discharges in tissue-printing by means of hydrosulphite compounds.—E. B.

Modern Violet and Blue 1900; New method of fixing ——. C. Favre. Sealed communication 1406, dated July 27, 1903. Bull. Soc. Ind. Mulhouse, 1906, 133—134.

BLUE 1900 yields an Alizarin Blue shade, whilst Modern Violet gives a much more violet tone of blue, of great fastness to light and soaping, when printed on cotton with the addition of tannin if the goods, after steaming, be passed through a bath containing sodium bichromate, *e.g.*, 2½ grms. per litre at 25° R. The depth and brightness of the shades obtained can be varied considerably by altering the temperature and concentration of the chroming bath. The following are the printing-mixtures

commended:—(1) 40 grms. of Blue 1900 in powder,, litre of acetic acid, ¼ litre of water, ¾ litre of starch, id tragacanth thickening, $\frac{2}{10}$ litre of tannin solution (1:1).) 120 grms. of Modern Violet, 40 per cent. paste, $\frac{1}{10}$—$\frac{1}{10}$ tre of acetic acid, $\frac{1}{10}$—$\frac{1}{10}$ litre of water, $\frac{1}{10}$—$\frac{3}{10}$ litre of starch id tragacanth thickening, $\frac{2}{10}$ litre of tannin solution. hese printing-mixtures, if printed with the addition of tric acid on cloth prepared with aluminium acetate, can rve to produce a fast blue on a Turkey-red ground. —H. L.

eport on the sealed communications 1406, *dated July* 27, 1903, *and* 1442, *dated January* 15, 1904, *of C. Favre, referring to a new method of fixing Modern Violet, Blue* 1900, *and derivatives of Gallocyanine.* O. Alliston. Bull. Soc. Ind. Mulhouse, 1906, 134—135.

HE author in general confirms the results obtained by . Favre in his communication 1406 (see preceding ostract), and states that the latter now adds 3—4 grms. oxalic acid per litre of printing colour, thereby in- reasing the solubility of the dyestuffs, and improving ie shades obtained.—H. L.

English Patents.

hreads, films, and laminæ from viscose; Preparation of ——. S. Peessarer, St. Petersburg. Eng. Pat. 16,583, Aug. 15, 1905.

HE method consists in treating viscose in aqueous olution with salts of aniline, naphthylamine, pyridine, and ther organic bases, whereby an insoluble preparation of ellulose is obtained, the dyeing of which may be effected t the same time by the addition of reagents capable of orming colour effects.—D. B.

olychromatic printing; Process of ——. J. J. Hart, Sydenham. Eng. Pat. 12,128, June 10, 1905.

EE Fr. Pat. 356,153 of 1905; this J., 1906, 17.—T. F. B.

alicoes and other woven fabrics; Apparatus for printing ——. I. V. Hulme, Didsbury. Eng. Pat. 18,168, Sept. 8, 1905.

OR printing scarfs and also continuous patterns on woven abrics, the articles are made to pass under a cylinder, eneath which a roller is mounted, receiving its motion om the cylinder. An endless perforated metal sheet stencil band passes between the cylinder and roller, id under the latter a wooden trough is fixed, containing ie colour or other solution, in which the roller revolves, ereby imparting the coloured design to the fabric. —D. B.

aper, textile fabrics, or the like; Apparatus for spraying fluid upon the surface of ——. C. A. Hanitzsch, Manchester. Eng. Pat. 20,220, Oct. 6, 1905.

PRAYING nozzles, communicating with the colour or other uid container, are mounted at any suitable part in the ngth of the fabric to be decorated. They are worked by eans of compressed air, and are fitted with a screwed ead, which enables the distance between the fluid and air utlets to be adjusted, so as to regulate the fineness of the pray. The container may be divided into compart- ents for the simultaneous employment of various colours. is provided with means for stirring and agitating the uid during the spraying operation, or it may be caused oscillate or otherwise move so as to bring about suf- icient agitation.—D. B.

rinting fabrics and wall papers; Machines for ——. H. H. Lake, London. From Companhia Manufactora Flumineuse, Rio de Janeiro, Brazil. Eng. Pat. 25,054, Dec. 2, 1905.

Collodion for artificial silk; Compression of ——, *by special solvents.* Soc. Anon. des Plaques et Papiers Phot. A. Lumière et ses Fils. Fr. Pat. 361,323, April 4, 1905.

THE use of water for operating the hydraulic piston in apparatus in which the collodion is supplied to the spinning device under a pressure produced on the hydraulic principle, suffers from the disadvantage that the collodion becomes clotted when traces of the water leak between the piston and the cylinder wall. According to the present invention the hydraulic medium employed is a solvent of nitrocellulose, preferably amyl acetate, which is pumped into the cylinder and pressure accumulator in the same way as water in an ordinary press. —J. F. B.

Collodion for artificial silk; Preparation of a concentrated ——. Soc. Anon. des Plaques et Papiers Phot. A. Lumière et ses Fils. Fr. Pat. 361,324, April 4, 1905.

A FLUID collodion is prepared by dissolving 300 parts of nitrocellulose in 200 parts of methyl alcohol, 200 parts of ethyl alcohol, and 1600 parts of ether. Owing to the excess of ether this collodion is very fluid, and can be easily filtered under a slight pressure. The collodion is then distilled in a vessel provided with stirrers, until 1000 parts of ether have been driven off and condensed for future use. The concentrated collodion is cooled, and, having already been filtered and freed from air whilst in the dilute condition, it can be directly stored in closed vessels ready for spinning.—J. F. B.

Collodion [for artificial silk]; Filter-press for ——. Soc. Anon. des Plaques et Papiers Phot. A. Lumière et ses Fils. Fr. Pat. 361,329, April 5, 1905.

FOR the filtration of collodion for the preparation of artificial silk, a continuous roll of filtering medium is provided outside the press. A portion of the fabric is clamped tightly over the perforated support by means of a screw-head, and the collodion is admitted under pressure from below through a pipe provided with a stop-cock. When the filtering surface has become clogged, the stop-cock is closed, the conduit for filtered collodion is also closed, the screw-head is raised slightly, and a new filtering surface is pulled through from the roll, and is clamped down ready for use.—J. F. B.

Silk; Process for the manufacture of artificial ——. E. Crumière. Fr. Pat. 361,048, Nov. 27, 1905.

OZONE or ozonised air is employed in treating cellulose in the manufacture of artificial silk. To this end the cellulose, in the form of cotton, ramie, &c., is exposed, "in contact with a solution of caustic soda or potash," for about half an hour to the action of the gas. The cellulose thus treated, it is stated, rapidly dissolves when it is immersed in a cupro-ammoniacal solution, giving a solution of a consistency suitable for the manufacture of threads. It is recommended to add metallic copper to the ammoniacal solvent, for the purpose of reacting

with the ammonia liberated, and of replacing in it the "copper" absorbed by the cellulose during the first stages of its action upon the cellulose.—E. B.

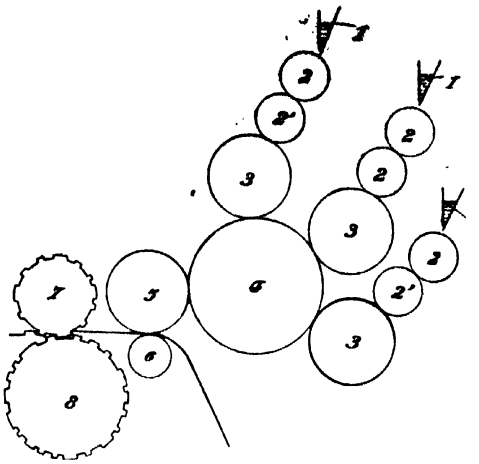
Silk; Process for the manufacture of brilliant threads of artificial ——, by precipitating cellulose in alkaline solutions. Soc. Gén. de la Soie Artificielle Linkmeyer. Fr. Pat. 361,061, Dec. 4, 1905.

In manufacturing artificial silk from cupro-ammoniacal solutions of cellulose, the threads produced, after passing into fixing or forming baths of "salts," or caustic soda or potash, are, according to this invention, freed from most of the ammonia present in them, before the rest of this is removed by treatment with dilute acid. This may be effected, as described in Fr. Pat. 347,960 (this J., 1905, 438), by simple evaporation in the air, but it is preferably accomplished by forcing or aspirating air or other suitable gases through the threads, wound, for example, in the moist state upon a perforated cylinder, or, still better, by using solutions of salts, such as sodium carbonate, potassium carbonate, "chromates, phosphates, oxalates, borates, iodides, &c.," which have the property of "absorbing" the ammonia, and of yielding with the cupric hydroxide in the threads, compounds which are insoluble in water, but easily soluble in acids. The solutions may, conveniently, be applied to the threads wound upon perforated reels.—E. B.

Scouring, &c., of wool and other textile fibres; Machine for ——. R. Kleinjung. Fr. Pat. 362,448, Jan. 11, 1906.

The material to be treated is fed in between two endless bands which pass in a zigzag direction through a series of compartments containing the various liquids employed. The liquid passes from one compartment to the next in the opposite direction to the movement of the material. The travelling bands can move relatively to one another, and can exercise a pressure on the material, and also a rubbing effect.—A. B. S.

Dyeing preparations containing, as fixing agents, proteids, especially maizine, of vegetable origin, and dyestuffs; New ——. E. Donard and H. Labbé. Fr. Pat. 361, 121, Dec. 27, 1905.



Maizine, the proteid substance derived from maize (this J., 1902, 1464 and 1548; 1905, 853), and the glutens of wheat and other cereals, are introduced in a powdered condition into hot aqueous solutions of basic and acid dyestuffs. The "zéo-" and "glutino-colorines" thus produced are collected and dried. Textile tissues and other materials are coloured with them either by fixing them upon the latter as pigments by means of suitable "agglutinants," or by dissolving them in volatile solvents, such as alcohol, acetic acid, "formaldehyde," aniline, &c., and thus applying them, the colour-lakes becoming fixed upon the tissues, &c., when the solvents are volatilised. They resist, it is stated, washing and soaping. Maizine may be chemically modified by dissolving it in a dilute solution of caustic soda, and precipitating it from this solution with a mineral acid. The product, "maizine S," is employed in the same manner as ordinary maizine, but it gives colour-lakes which are soluble in alkalis and alkaline salts, such as borax.—E. B.

Dyeing threads or fabrics containing acetylated cellulose; Process for ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 362,721, Jan. 26, 1906.

Although acetylcelluloses can only be dyed very feeble shades by aqueous solutions of dyestuffs, it is found that, by addition of another solvent, such as acetone or an alcohol, to the dye-bath, any depth of shade can be produced. For example, 1 part of Naphthol Yellow S is dissolved in 50 parts of water and 50 parts of alcohol, and the threads containing acetylcellulose are dyed by immersion for one hour at 70° C.—T. F. B.

Paper, tissues, &c.; Machine for printing and embossing ——. C. H. Jeanson. Fr. Pat. 360,975, Dec. 27, 1905.

Paper, tissues, &c., are printed in designs in several colours, and embossed by means of a combined printing

and embossing machine. The printing "colours," inks, are conveyed from receptacles, 1 (see figure), t trains of rollers, 2, 2', to rollers, 3, bearing portions the designs to be printed. Each of the latter rolle transfers its colour to a smooth roller, 4, which in tu supplies the printing roller, 5, bearing the comple design, with colour. The tissue, &c., to be printed passed between this roller and a supporting roller, After being printed, it is embossed by the cylinde 7 and 8. Modifications of the apparatus are described b means of which the tissues, &c., may be simultaneous printed and embossed, or may be printed, embossed, a again printed. The tissues, &c., may be coloured b means of an embossing cylinder, a train of three cylinde being in this case employed, and "colour" being supplie to one of them.—E. B.

Tapestry, &c.; Colour distributor for the manufactu of ——. G. F. Steiner. Fr. Pat. 362,397, Jan. 1 1906.

The distributor consists of a vessel divided into a numb of compartments to hold the various colours. Each these compartments communicates with all the delive tubes which lead the colour to the orifices, where it com in contact with the material to be printed. The colo holders are separated from the delivery tubes by mea of a perforated plate, the perforations in which are arranged that the desired colours are allowed to r into special tubes according to the design to be printed. —A. B. S.

Formaldehyde-hydrosulphites; Production of —— Badische Anilin und Soda Fabrik. Fr. Pat. 362,44 Jan. 10, 1906. Under Int. Conv., Dec. 4, 1905.

See Eng. Pat. 81 of 1906; this J., 1906, 260.—T. F. B.

Formaldehyde-sulphoxylates and formaldehyde-hydr sulphites [Discharging agents]; Production of alka ——. J. Rohner. Fr. Pat. 362,405, Jan. 13, 1906.

This process depends on the reduction of formaldehyd sodium bisulphite by means of zinc dust or other fine divided metal in presence of oxalic acid. The reactio takes place thus:—

$$CH_2O.NaHSO_3 + Zn + (COOH)_2 = (COO)_2Zn + H_2O + CH_2O.NaHSO_2.$$

The insoluble oxalate of zinc is filtered off from the solutio of formaldehyde-sodium sulphoxylate, and the latter evaporated *in vacuo*. 250 parts of sodium bisulphit (25 per cent. of sulphur dioxide) are mixed with 110 part of formaldehyde (29 per cent.); a considerable rise temperature occurs, and combination takes place betwee the two substances. 110 parts of zinc powder are adde to this solution, and the whole heated to boiling; 12 parts of crystallised oxalic acid are then added, wit

constant stirring, a little at a time. The boiling is continued until the solution is neutral, when the zinc oxalate is filtered off, and the solution evaporated *in vacuo* to a syrup which crystallises on cooling. A similar process can be employed to obtain a solution of pure hydrosulphite:—

$$2.NaHSO_2 + Zn + (COOH)_2 = (COO)_2Zn + 2H_2O + Na_2S_2O_4.$$

Sodium bisulphite is mixed with zinc dust and oxalic acid in aqueous solution; on cooling and stirring until the oxalic acid has disappeared, one obtains, after separation of the zinc oxalate, a solution of pure hydrosulphite. By adding the necessary amount of formaldehyde and evaporating, the "formaldehyde-hydrosulphite compound" is obtained.—A. B S.

Textiles; Rendering —— impermeable. J. Cottin and D. Four. Fr. Pat. 360,946, March 20, 1905.

TEXTILE materials, composed of wool and silk, are rendered impermeable to water, by treatment, after dyeing, with aluminium salts, rosin, paraffin wax, and india-rubber. In dyeing, *e.g.*, with Naphthylamine Black, alum and sodium sulphate are employed as "assistants," the dyed materials, after wringing or squeezing, and "hydro-extracting," being immersed in a bath of sodium sulphoricinoleate (Turkey-red oil, 1 per cent.), acidulated with acetic acid (0·25 per cent.), and being thereupon dried. After being steeped for an hour, at a temperature of 5° C., in a bath of aluminium sulphate (3 per cent.) and "alumina" (3 per cent.), and again dried, they are immersed in succession in solutions (in solvent naphtha) of rosin (0·05 per cent.), paraffin wax (1 per cent.), and india-rubber (1 per cent.) respectively, being dried after each immersion.—E. B.

(*Continued from page* 638.)

Selenium; Behaviour of —— in the sulphuric acid manufacture. S. Littmann. Z. angew. Chem., 1906, 19, 1039—1044; 1081—1089.

THE mode of occurrence of selenium in the chamber process is not what would be expected from our present knowledge of its behaviour, which may be summed up as follows:—Selenium exists as red selenium, the form in which it is precipitated from acid which contains it; as grey or metallic selenium, into which the red form is converted by rise of temperature, and which is more stable and less chemically active than the red form; and as collodial selenium. It is not oxidised by nitric acid to a higher state of oxidation than the dioxide (selenious acid), and this is reducible by sulphur dioxide or sulphurous acid to selenium again. Selenium dissolves in strong sulphuric acid to a green solution.

No selenium is deposited in the dust-chambers between the burner-flues and the Glover towers; the gases in the dust-chambers contain no selenium dioxide, nor do those in the Glover towers, though the Glover acid shows both selenium and the dioxide. The amount contained as dioxide, and that deposited as selenium from the red acid, do not together make up, however, more than about 2—4 per cent. of the total selenium contained in the pyrites. If the Glover acid contain any remaining nitrogen compounds, its selenium is entirely present as dioxide; but when it is completely denitrated, some, if not all, of the selenium exists in a form which the author provisionally terms "combined" selenium, and this is readily reduced to red selenium or oxidised to dioxide. In the Gay-Lussac acid, any selenium present is there as dioxide.

In the chambers, selenium exists in the immediate vicinity of the entrance, but at a little distance from it and throughout the rest of the chambers the gases contain only the dioxide, as does the acid formed. With a divided entry-pipe which delivered gases to the chambers at various points along their whole length, the author found selenium at every point of entry, and the acid contained "combined" selenium, which was afterwards partly precipitated, partly converted into dioxide.

In the concentration of the chamber acid, selenium is difficult to get rid of. Reducing substances, like charcoal, convert it into the red form, but it does not readily subside, and as concentration proceeds, it dissolves again in the acid as the green compound, $SeSO_3$. This, as the temperature rises, becomes oxidised to dioxide at the expense of some of the acid. The concentrated acid thus contains practically as much selenium as the chamber acid from which it was made. The concentrated acid begins to dissolve selenium, forming the green solution at 65° C., and complete solution occurs below 140° C., at which temperature there is already considerable evolution of sulphur dioxide, and hence formation of selenium dioxide. This evolution is very rapid at 210° C., and at 260°—280° C. the oxidation of the selenium is complete. Where the distillates are collected during concentration, the middle portions only contain selenium; neither at a low temperature, when the acid has not dissolved the selenium, nor at a high temperature, when the selenium is completely oxidised, does any pass over, but at intermediate temperatures, while the green solution exists, some volatile selenium compound is formed, and distils over.

The author considers that these phenomena all point to the existence of a selenium compound intermediate between the element and the dioxide—possibly SeO or a derivative of it, which is readily reduced to selenium, or further oxidised. The green solution he looks on as possibly a compound of this with sulphur dioxide (SeO,SO_2) or of both with sulphur trioxide ($SeO,SO_2.SO_3$), or at least as convertible into such a compound by intramolecular change. The solution of selenium in concentrated sulphuric acid, the precipitation of selenium from the solution by dilution, and the formation of selenium dioxide at a high temperature, are represented by the equations:—

$$Se + 2SO_3 = SeSO_3.SO_3.$$
$$SeSO_3 + H_2SO_4.H_2O = 2H_2SO_4 + Se.$$
$$SeSO_3.SO_3 = SeO_2 + 2SO_2.$$

The compound, $SeSO_3$, may act as $SeO.SO_2$. Either SeO itself or possibly this compound of it is volatile, and it is in this form that selenium is carried with the flue-gases right through into the chambers.

The ready oxidation of this compound, and its easy reduction to selenium, suggest as a means of reducing the amount of selenium in the chamber acid when working with seleniferous pyrites, to carry on the process with as little excess of nitrogen-compounds as possible. The author has found that by his method of dividing the gases for entry into the chambers, this condition is fulfilled, and he has succeeded in lessening considerably the content of selenium dioxide in the acid, and increasing correspondingly the amount of selenium precipitated in the mud; where it is possible to filter the acid from suspended selenium, an acid containing still less selenium is obtained. From chamber acid or stronger acids it is not practicable to remove dissolved selenium completely; but, from weaker acids it can be removed, most readily by precipitation by means of hydrogen sulphide or barium sulphide.

For the production of selenium from the Glover- or chamber-mud, the mud is treated with concentrated sulphuric acid and a quantity of sodium nitrate corre-

sponding to the amount of selenium. The mixture, diluted not below 85 per cent. of monohydrate, is well stirred, and then steam is blown in till the sp. gr becomes 1·25, any oxides of nitrogen still remaining being expelled by a stream of air. The solution is filtered, and in the filtrate and washings, after addition of hydrochloric acid or common salt, the selenium is precipitated by a stream of purified sulphur dioxide as a gelatinous mass, which, by warming and proper treatment, can be clotted together into a ball. This, after washing with water, and drying at 105° C., gives a 99 per cent. selenium.

For the analytical detection of selenium, its reduction, and precipitation as such must be relied on; stannous chloride is the most efficient agent. A red colour in the acid, due to nitroso sulphur compounds of iron, may sometimes suggest selenium, but this is destroyed on reduction, and gives, of course, no red precipitate of selenium. The quantitative determination of selenium in sulphuric acids is carried out by the author as follows. The substance is repeatedly treated in the water-bath with strong nitric acid, and evaporated down. Nitrogen oxides are removed by a stream of air passed first through the strong and then through the diluted solution; the solution is then treated with N/10 permanganate, and the excess of this titrated by oxalic acid. The amount of permanganate used is a measure of the selenium which has been oxidised from selenious acid to selenic acid.

—J. T. D.

Chamber process; Practical details of the ——. S. Littmann. Z. angew. Chem., 1906, **19**, 1177–1188.

In a set of three chambers, one 36 m., and the others each 30 m. long, the usual method of working was to send the gases from the Glover tower into the large and one of the small chambers, the united gases from the farther ends of these chambers passing through the third chamber. The large chamber having to be thrown out for repairs, the author used the opportunity to carry out some large-scale experiments. In the first small chamber were arranged, in vertical lines along a vertical plane parallel to the length of the chamber, and 2 m. from its centre, a number of cups, and over a period of some weeks' working the acid condensed in these was examined at intervals (quantity, concentration, nitrous contents, selenium, iron, &c.). Three cups were placed above one another (1 m. from floor, mid-height, 1 m. from roof) at each of four points in the chamber's length (4 m. from front wall, mid-length, 4 m. from back wall, 1 m. from back wall). Each cup was protected by a leaden lid above it from any drip of acid from above. Three sets of observations were made. In the first, the three chambers were working as usual. In the second, the large chamber was thrown out, and the smaller chamber was therefore working under forced conditions. In the third, the same conditions held, but the Glover gases, instead of entering the chamber by a single pipe in the end wall, were introduced at the top of the chamber by six openings distributed along its whole length. The detailed results are shown in a diagram in the paper, but the most important conclusions may be summarised as follows:—

Productivity of the chamber.—In expt. 1, 4·52; expt. 2, 6·56; expt. 3, 7·48 kilos. of 50 per cent. acid per cb. m. per 24 hours. *Nitre-consumption*, 1, 0·58; 2, 0·59; 3, 0·48 per cent.

It thus appears (comparing 2 and 3) that the alteration in the method of introducing the gases increased the rate of working of the chamber by 14 per cent., and at the same time reduced the nitre-consumption. Moreover, the floor-acid in expt. 3 was much less seleniferous (see preceding abstract), and the gases leaving the final chamber were colourless, while in both of the other experiments they were red. The examination of the acid in the cups showed that while in expts. 1 and 2, the production of acid was more considerable in the lower than the upper part of the chamber, in expt. 3 it was almost uniform throughout the height. The acid in expts. 1 and 2 contained in all parts more nitrous compounds than that in expt. 3; but while their proportion rose steadily and considerably in expts. 1 and 2 from front to back of the chamber, it varied very much less in expt. 3. The superior working of the chamber in the third experiment is attributed by the author to the greater uniformity of the conditions which arises from the much more thorough and complete mixture of the gases. The tendency of the nitrous gases is to rise, and in the ordinary method a certain amount of separation does occur, so that the acid is made chiefly in regions where there is a relative excess of nitrous gases, and consequently removes in solution an undue proportion of these, while there are other regions in which the reaction cannot proceed because of the insufficiency of nitrous compounds. In his opinion nitrosulphuric acid represents a stable and highly oxidised form of combination of nitrogen, which in a properly working chamber should not be formed at all; the work of oxygen transference should, he thinks, be effected by the formation and hydrolytic transformation of "nitrosisulphonic acid":—

$$NO + SO_2 + O + H_2O = OH.NO.HSO_3$$
$$OH.NO.HSO_3 + xH_2O = H_2SO_4.xH_2O + NO.$$

—J. T. D.

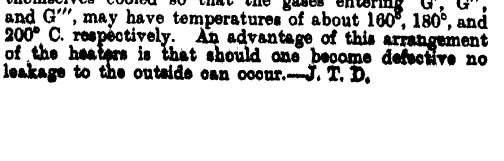
Glover tower process; Theory of the ——, and possibility of producing sulphuric acid in towers. M. Neumann. Chem.-Zeit., 1906, **30**, 598.

The reaction in the Glover tower and that in the chamber are identical as far as the formation of nitrosylsulphuric acid is concerned—

(1) $2SO_2 + 2NO + 3O + H_2O = 2SO_5NH$;

but whereas in the chamber this reacts with water alone—

(2) $2SO_5NH + H_2O = 2H_2SO_4 + N_2O_3$;



in the Glover tower it reacts with water and sulphur dioxide—

(3) $2SO_5NH + SO_2 + 2H_2O = 3H_2SO_4 + 2NO$;

and thus three molecules of sulphuric acid are formed through the action of the same quantity of nitric oxide which in the chamber forms only two. The author regards each of the reactions (1) and (3) as consisting of two stages—

α. $2NO + O = N_2O_3 + n$ cal.
β. $2SO_2 + N_2O_3 + O_2 + H_2O = 2SO_5NH + 2x$ cal.
γ. $2SO_5NH + H_2O = 2H_2SO_4 + N_2O_3 + 2y$ cal.
δ. $N_2O_3 + SO_2 + H_2O = H_2SO_4 + 2NO + x + y - n$ cal.

Thus $\alpha+\beta$, or (1), evolve $2x+n$, and $\gamma+\delta$, or (3), evolve $x+3y-n$ calories; where $x+y=54$ is the heat of combination SO_2, O, H_2O, and $n=20·1$ is that of 2NO, O. As the denitration in the lower parts of the tower implies the endothermic reduction of 1 mol. of nitrogen trioxide to 2 mols. of nitric oxide, with absorption of n calories, which are evolved again in the upper parts, the author suggests a series of towers, the upper parts of which are cooled, and the lower parts heated, the apparatus being so arranged that as the ratio of oxygen to sulphur dioxide increases, and consequently the tendency against the reduction of nitrogen trioxide to nitric oxide, the gases shall be heated to a correspondingly higher temperature to favour the endothermic reaction. The figure shows diagrammatically his proposal.

G′, G″, G‴, are three towers; the gases from G′, enter G″, only after passage through the heater, V′, and those from G″, reach G‴, after passage through V″. These heaters are contained in the flue from the pyrites burners, and are heated by the burner gases, which are themselves cooled so that the gases entering G′, G″, and G‴, may have temperatures of about 160°, 180°, and 200° C. respectively. An advantage of this arrangement of the heaters is that should one become defective no leakage to the outside can occur.—J. T. D.

Platinum; Corrosion of —— by sulphuric acid. L. Quennessen. Comptes rend., 1906, **142**, 1341—1343. (See also this J., 1906, 24 and 314.)

COMMERCIAL platinum is more readily attacked than the pure metal. Pure platinum, in absence of oxygen, is hardly affected by strong sulphuric acid even at 450° C., but the presence of oxygen causes the attack to be very sensible, some absorption of oxygen at the same time occurring. If the acid should contain anhydride, it will attack platinum even in the absence of oxygen, the anhydride becoming reduced, and thus furnishing oxygen. The author refers to the work of Dittmar (J. Chem. Soc., 1869, **7**, 446) on a similar subject.—J. T. D.

Nitric acid and nitrates; Direct synthesis of ——, from their elements, at the ordinary temperature. M. Berthelot. Comptes rend., 1906, **142**, 1367—1379.

THE author has examined the effect of the silent discharge of the induction coil on mixtures of nitrogen and oxygen in presence of water or of alkali hydroxide, using both a stream of gas passing through the apparatus, and also a fixed contained volume. The primary current was 12 ampères at 6 volts, and the poles of the coil were 20 mm. apart. The coil was used both with and without a condenser. It was found that the high tension of the coil was necessary (no effect was produced by connecting the apparatus directly with the public alternating supply at 100 volts), but that the condenser was practically without influence. In the circulation experiments, 0·0192 grm. of nitric acid per hour was produced from half a litre of air, or about 14 per cent. of the total amount possible. No effect was produced by substituting alkali hydroxide for water in the apparatus. Neither ammonia nor nitrous acid was produced. In the constant volume experiments, whether the gases were mixed in the proportions $N_2 : O_5$, or there was excess of nitrogen, reaction occurred to the (practically) complete disappearance of oxygen; and here, also, no other reaction than the direct formation of nitric acid took place. In these experiments, measurements of pressure and time showed an acceleration of the reaction after the beginning, followed by a gradual retardation as the pressure (and hence the concentrations of the reacting gases) diminished, so that the theoretical completion of the reaction would occur only after infinite time. It is to be remembered that the reactions here concerned—

$$N_2 + O_5 + H_2O + Aq = 2HNO_3 \text{ dilute};$$

or,

$$N_2 + O_5 + H_2O \text{ gas} = 2HNO_3 \text{ gas};$$

are exothermic, and differ in this from the formation in the arc of nitric oxide or nitrogen peroxide from their elements.—J. T. D.

Barium sulphate and barium chromate: Equilibrium in the reactions between potassium chromate and ——. M. Scholtz and R. Abegg. Z. Elektrochem., 1906, **12**, 425—428.

AT ordinary temperatures the reaction between barium sulphate and potassium chromate is only complete after a number of days, but if the solutions are maintained near 100° C., the time necessary to attain equilibrium is considerably curtailed. It appears that barium chromate is formed more quickly than barium sulphate, but that the sulphate in solution subsequently reacts with the precipitate, causing re-solution of the chromate. By working with varying proportions of sulphate and chromate it is found that in the presence of considerable excess of chromate, the barium sulphate becomes much less soluble, indicating the formation of a solid solution in which barium sulphate exists in a very dilute state. Similarly with large excess of sulphate the barium chromate becomes less soluble. The equilibrium in the reaction between barium carbonate and potassium chromate is much more quickly attained, at 100° C. only requiring some 12 hours. In this case barium carbonate is formed most rapidly, but is subsequently slowly redissolved; since, however, the ratio of chromate to carbonate varies with the relative quantities of the potassium carbonate and potassium chromate taken, a solid solution is also formed with this precipitate.

—R. S. H.

Potassium ferrocyanide; Action of light on ——. G. W. A. Foster. Chem. Soc. Proc., 1906, **22**, 136.

WHEN a neutral or alkaline solution of potassium ferrocyanide is exposed to light, ferric hydroxide is slowly precipitated; in presence of alkali sulphide, ferrous sulphide is thrown down.

No precipitation takes place if the solutions are protected from light; the action is therefore entirely photochemical. Potassium ferrocyanide is, in solution, dissociated in the usual manner into potassium ions and the complex "ferrocyan" ions $[Fe(CN)_6'''']$: this is in absence of light. On exposure to light, the complex ion is dissociated into iron ions and cyan ions, and on removing the source of light the complex ferrocyan ion is regenerated. Thus no precipitation of iron can take place in absence of light.

The relations Fe : (CN) were always below the theoretical 1 : 6, and this was found to be due to the oxidation of cyanide under the influence of light to cyanate and polymerides. In presence of alkali sulphide the cyanide is almost entirely converted into thio-cyano-compounds.

The source of light used was a mercury vapour lamp of quartz. It was water-cooled, and, using a direct current of 5—6 ampères at 240—250 volts, gave a very intense light, rich in ultra-violet radiation.

Ferro-cyanogen compounds; Reduction of blue ——. M. Kohn. Z. anorg. Chem., 1906, **49**, 443—444.

PRUSSIAN blue and Turnbull's blue are readily reduced by sodium bisulphite in presence of stannous chloride, provided the bisulphite be in considerable excess. Stannous chloride solution is added to excess of a concentrated solution of sodium bisulphite acidulated with a small quantity of dilute sulphuric acid. The mixture acquires an intense yellow colour, which disappears on standing. If freshly-precipitated Prussian blue or Turnbull's blue be introduced into this mixture, reduction takes place in the cold, and the colourless mixture can be kept for several hours in open test-tubes, without the blue colour returning. The blue compounds are regenerated immediately on addition of an oxidising agent, such as bromine water. The author considers that the reduction is effected by hyposulphurous (hydrosulphurous) acid formed according to the equation: $2NaHSO_3 + SnCl_2 + 2HCl = SnCl_4 + Na_2S_2O_4 + 2H_2O$, and the fact that the blue compounds mentioned are readily reduced by sodium hyposulphite is in agreement with this view. It has been pointed out frequently that hydrogen sulphide is formed by the action of stannous chloride on sulphurous acid, but this is only in presence of excess of stannous chloride, whereas the reducing action described above is in presence of excess of sulphurous acid.—A. S.

Lead oxychloride. R. Ruer. Z. anorg. Chem., 1906, **49**, 365—383.

THE author constructed the melting-point curve of mixtures of lead oxide and lead chloride in order to determine what compounds are formed when these two substances are fused together. It was found that three compounds ($PbCl_2$, PbO), ($PbCl_2$, 2PbO), and ($PbCl_2$, 4PbO), are formed in this way. The compound, $PbCl_2$,PbO, which occurs naturally as matlockite, forms long, thin, colourless needles, yielding a nearly white powder; it decomposes at 524° C. into a mixture of the compound, $PbCl_2$,2PbO, with about 36 per cent. of lead oxide, which fuses completely at 615° C. The compound, $PbCl_2$,2PbO, which occurs naturally as mendipite, melts without decomposition at 693° C. It forms long, glistening needles, which yield a nearly white powder. The compound, $PbCl_2$,4PbO, melts at 711° C. It forms glistening lamellar crystals, and yields a powder of an intense yellow colour.—A. S.

Bismuth peroxides, III. Oxidation of bismuth compounds by means of potassium persulphate in alkaline suspension, and the so-called "anhydrous bismuth tetroxide." A. Gutbier and R. Buenz. Z. anorg. Chem., 1906, **49**, 432—436.

THE authors have repeated Deichler's experiments on

the action of potassium persulphate on alkaline suspensions of bismuth compounds (this J., 1899, 616), but find that no definite compounds are produced, the reaction product consisting of a mixture of varying composition containing bismuth peroxides (see also this J., 1906, 263, 264). The concentration of the alkali has considerable influence on the composition of the reaction-product. The authors are thus unable to confirm Deichler's statement as to the existence of "anhydrous bismuth tetroxide."—A. S.

Phosphorus pentasulphide and ammonia; Reaction between ——. Thiophosphates and thiophosphoric acids. A. Stock and others. Ber., 1906, **39**, 1967—2008.

PHOSPHORUS pentasulphide dissolves in excess of liquefied ammonia, forming a yellow compound, ammoniumiminothiopyrophosphate, $(SNH_4)_2P(:NH).S.P(:NH)(SNH_4)_2$. If the solution be allowed to stand for some time, this yellow compound unites with another molecule of ammonia, and is converted into two colourless salts, one of which, triammoniumiminotrithiophosphate, $NH:P(SNH_4)_3$, crystallises out, whilst the other, diammoniumnitrilodithiophosphate, $N:P(SNH_4)_2$, remains in solution. Triammoniumiminotrithiophosphate, when allowed to stand in an exsiccator over sulphuric acid, loses ammonia, and yields at the ordinary temperature the corresponding diammonium salt, and at 100° C., the mono-ammonium salt. The disodium salt can be obtained by treating the triammonium salt with sodium ethylate. By shaking the triammonium salt with ether, to which 1 per cent. of water has been added, the imino group is attacked, and triammoniumtrithiophosphate, $OP(SNH_4)_3$, is produced, which is more stable than the imino compound, but decomposes slowly when its solution is allowed to stand, with formation of the corresponding diammonium salt. The alkaline-earth salts of trithiophosphoric acid are soluble in water. By heating triammoniumtrithiophosphate in a current of sulphuretted hydrogen, yellow monoammoniumdithiometaphosphate, $OPS(SNH_4)$, is produced. Triammoniumiminotrithiophosphate when heated in a current of sulphuretted hydrogen, yields the corresponding free iminothiophosphoric acid, $NH:P(SH)_3$, which, however, is not very stable. In contact with water it decomposes according to the equation:

$$(NH)P(SH)_3 + 3H_2O = OP(SNH_4)(OH)_2 + 2H_2S.$$

The monoammoniummonothiophosphate thus produced, loses hydrogen sulphide on heating, and yields ammonium metaphosphate. Iminothiophosphoric acid combines with anhydrous hydrogen chloride to form a white hydrochloride which, when heated to a high temperature, yields among other products, iminothiopyrophosphoric acid, $(SH)_2P(:NH).S.P(:NH)(SH)_2$. On heating iminothiophosphoric acid in a vacuum to 300° C., hydrogen sulphide is split off, and thiophosphoric acid nitrile, NPS, is produced. The latter is not decomposed by water in the cold; on heating to redness it yields phosphorus nitride, P_3N_5. The free thiophosphoric acids are produced when the ammonium salt is treated with anhydrous hydrogen chloride, but it was only found possible to isolate thiopyrophosphoric acid, $(SH)_2OP.S.PO(SH)_2$, and even this not in a pure state. The free acids are all unstable substances. Other sulphides of phosphorus besides phosphorus pentasulphide react in a somewhat similar manner with liquefied ammonia.—A.S.

Radium; Influence of —— on hydrogen-chlorine and oxyhydrogen mixtures. W. P. Jorissen and W. E. Ringer. Ber., 1906, **39**, 2093—2098.

HYDROGEN and chlorine exposed to the radiation from radium slowly combine to form hydrochloric acid. In 33 hours 1·13 c.c. of the mixed gases thus combined. No effect was produced upon oxyhydrogen mixture. The different result obtained by Davis and Edwards (this J., 1905, 266) arises from their having brought the radium compound into actual contact with the gases.
—J. T. D.

Air; Conductivity of ——, when in contact with oxidising substances. W. P. Jorissen and W. E. Ringer. Ber., 1906, **39**, 2090—2093.

WHEN air is mixed with traces of the vapour of oxidisable organic substances—triethylphosphine, pyrogallol, benzaldehyde, &c., its electrical conductivity is diminished; probably because, though increased ionisation occurs, the ions of the air are loaded by the formation of so-called "molions." The vapour of oxidising phosphorus increases the conductivity, but the addition of pinene, for example, to the air which has been previously subjected to the action of the phosphorus products, rapidly reduces it again. The authors have investigated the limits of pressure at which the oxidation of phosphorus occurs in oxygen, when in contact with mixtures of sulphuric acid and water. While the limit with concentrated sulphuric acid lies between 585 and 538 mm., and with water at 600 mm., it lies between 437 and 336 mm., with 75 per cent. acid, and between 564 and 545 mm. with 50 per cent. acid.—J. T. D.

Ammonia as a by-product in coke-making; Use of gypsum for the recovery of ——. H. Warth. III., page 686.

Nitrate of soda statistics. W. Montgomery and Co. June 30, 1906. [T.R.]

THE following table gives figures as to the shipments, consumption, stocks, and prices from 1904 to 1906:—

		1904.	1905.	1906.
Shipments from South American ports to all parts for the six months ending 30th June	Tons	578,000	689,000	704,000
Ditto ditto for the twelve months ending 30th June	,,	1,463,000	1,587,000	1,638,000
Afloat for Europe on 30th June	,,	199,000	232,000	278,000

Salt; Manufacture of white —— from rock salt. H. Tee, Liverpool. Eng. Pat. 6611, March 29, 1905.

The rock salt to be purified is supplied to the upper part of a cupola furnace, the shaft of which is provided with a succession of narrow arches serving to support the salt while it is being heated and exposed to air and gases of combustion. The shaft is narrowed near its base to a restricted passage, above which the salt is held up by an inwardly projecting part, and descends, as it melts, into a chamber below, in which provision is made for injecting superheated steam, or carbon dioxide or monoxide, or air, into the molten mass. In a modified form of apparatus, the chamber near the bottom of the shaft communicates with a second chamber at its side, into which the molten salt flows, and into which air, steam, or gases may be injected, as in the first chamber, or in which the suspended impurities may be allowed to settle before discharging. (Reference is made to Eng. Pat. 8117 of 1903; this J., 1904, 749.)—E. S.

Alkaline prussiates; Manufacture of ——. G. E. Davis, London. Eng. Pat. 9793, April 26, 1906.

The ammonia distillate obtained from the product described in Eng. Pat. 26,566 of 1902 (this J., 1903, 1243), by its treatment in the ammonia still, is used in precipitating the "sulphide mud" therein named from galvanisers' spent pickle, or from other ferrous chloride or sulphate solution; and the "sulphide mud" so obtained is applied in producing the "alkali cream" which, in the said specification, is directed to be used to wash gaseous mixtures containing hydrocyanic acid or ammonium cyanide, with a view to the production of alkali cyanides. —E. S.

French Patents.

Copper sulphate contaminated with salts of iron; Process for the refining of ——, and for the direct extraction of copper from ores. R. Conodera. Fr. Pat. 362,342, Jan. 11, 1906. Under Int. Conv., Feb. 19, 1905.

The process is based upon the following facts:—(1) Ferric oxide is the weakest base of those commonly occurring in the hydrometallurgical treatment of copper ores, and if, therefore, a neutral solution containing ferric and copper sulphates be treated with cupric hydroxide, copper sulphate is formed, and the ferric sulphate is converted into an insoluble basic sulphate, or even into ferric oxide. (2) Hydrated ferrous oxide is oxidised by atmospheric oxygen to basic ferric sulphate, and if cupric hydroxide be present, this basic sulphate at the moment of its formation gives up part or the whole of its sulphuric acid, with formation of copper sulphate. In carrying out the process the solution containing copper and ferric sulphates is made to diffuse into a large porous mass containing copper oxide, which mass is then exposed to the air to effect the complete conversion of the ferric sulphate into an insoluble basic sulphate. The copper sulphate is afterwards recovered by lixiviation. According to another claim, roasted copper ore is treated with water to convert it into a porous mass containing copper oxide, and copper and ferric sulphates, which is exposed to the air, and afterwards lixiviated to recover the copper sulphate, the distinctive feature of this modification of the process being that no separate porous mass is necessary as in the method first described.—A. S.

Catalytic apparatus [Production of nitric oxide from ammonia]. Nordyke and Marmon Co. Fr. Pat. 362,434, Jan. 16, 1906.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 638.)

Boron-ultramarine. J. Hoffmann. Z. angew. Chem., 1906, **19**, 1089—1095.

The author has revised and extended the work of Knapp on this substance. While sodium sulphide and borax melted together give a yellow or brownish glass, the further addition of boric anhydride gives a glass of lighter or darker blue tint, according to the proportions used. A similar glass is obtained from boric anhydride and sodium sulphide, in which case, however, the proportion of boric acid must be very considerable. Mixtures used by the author are: (1) anhydrous borax 3·6, boric anhydride 1·5, sodium sulphide 0·9 grm.; or (2) boric anhydride 17, sodium sulphide 2 grms. The blue glass cannot be obtained if sulphur is substituted for sodium sulphide, but the addition to the borax and sodium sulphide glass of either phosphoric anhydride or alum gives the blue colour. A solution of sodium triborate saturated with hydrogen sulphide, evaporated to dryness, and the residue fused, also gives a blue glass. This "boron-ultramarine" is stable in air, and gives a light-blue powder. It is only slightly soluble in water, giving a colourless solution with alkaline reaction. Dilute hydrochloric acid dissolves it readily, and, on warming, the solution gives off hydrogen sulphide. The glass appears to contain sulphide and sulphate, but no thiosulphate. Specimens prepared in porcelain crucibles contain silica and alumina, but these are not essential to the colour, nor is moisture nor access of air, for the blue glass is obtained equally well by fusing the pure (and anhydrous) materials in a platinum crucible in an atmosphere of nitrogen. The lowest temperature of reaction is about 720° C., but continued exposure to a high temperature slowly decolorises the substance. The colour goes more rapidly if the heating be done in a stream of air or oxygen, but even in a hydrogen stream it disappears. This is due to loss of sulphur, for three portions of the same preparation, heated for successively increasing periods, so as to be deep blue, light blue, and decolorised, contained 0·52, 0·13, and 0·00 per cent. of sulphur respectively. Boron sulphide and sodium oxide melted together do not give a blue glass, so that in the blue glass the oxygen of the boric anhydride can be only partially, if at all, displaced by sulphur. The lowest proportion of boric anhydride which will give a blue glass corresponds to a triborate, and the best colours are obtained with mixtures corresponding to tetraborate. The resemblances between boron-ultramarine and ordinary ultramarine are pointed out, and the similarity or relationship between boron and aluminium insisted on. The author thinks it probable that the sulphur in boron-ultramarine, in whatever form it may exist, is there neither as elementary sulphur nor as sodium sulphide.—J. T. D.

Quartz glass. A. L. Day and E. S. Shepherd. Science, 1906, **23**, 670—672. Science Abstracts, 1906, **9 A**, 331.

To obtain clear quartz glass free from bubbles, the authors recommend the following process:—The fragments of quartz are placed in an electric furnace, the heating chamber of which is composed of a thin-walled graphite box, and heated rapidly to about 2000° C., whereby the silica is rapidly volatilised, and the silica vapour displaces the air enclosed between the grains of the charge. The mass is then subjected to a pressure of 500 lb. by means of compressed air, and the temperature is reduced to about 1800° C., and maintained thereat for some time.

The current is then turned off, and the pressure gradually reduced. By this process the authors have succeeded in preparing blocks of quartz glass, measuring 3 by 5 by ½ in., almost entirely free from bubbles, and only occasionally slightly stained with free silicon. The residual bubbles are very small, and not numerous enough to interfere with the use of the glass for lenses or other optical purposes. —A. S.

UNITED STATES PATENT.

Sheet-glass; Apparatus for drawing ——. J. W. Colburn and E. Washburn, Franklin, Pa. U.S. Pat. 823,581, June 19, 1906.

THE apparatus consists of a receptacle containing molten glass, means for drawing glass therefrom in sheet form in a longitudinal direction, and two conical rollers revolving in opposite directions, each having a portion of its surface dipping into the mass of molten glass in the receptacle, and a portion engaging the surface of the sheet as drawn, whereby these rollers serve not only to draw glass from the receptacle, but also to stretch the sheet laterally. A corrugated sheet-metal bait may also be provided, together with means for lowering it into and withdrawing it from the receptacle.—A. G. L.

X.—METALLURGY.

(*Continued from page* 642.)

Steel; Phenomena during melting of —— [*Gas-bubbles*]. A. Ruhfus. Stahl u. Eisen, 1906, **26**, 775—777.

THE smaller a casting, and the quicker the cooling, the more gas is retained in it. Samples taken at different stages from a Siemens-Martin furnace, quickly cooled, and then sawn, and the sections examined, showed that as the temperature rises, and the fluidity of the charge increases, the gas-bubbles concentrate towards the centre of the ingot, and then gradually diminish in size and number towards the exterior.—J. T. D.

Copper-steels. P. Breuil. Comptes rend., 1906, **142**, 1421—1424.

THE author has examined steels with 0·10 to 0·17 (series A) and with 0·28 to 0·41 (series B) per cent. of carbon, each series containing 8 members with 0, 0·5, 1, 2, 4, 8, 16, and 32 per cent. approximately of copper. Analysis showed the copper to be uniformly distributed in all save the 32 per cent. member of series B, the upper part of which contained 34·2 at the centre and 21·2 at the surface, the lower 74·8 at the centre and 24·4 at the surface; the two parts were clearly distinguishable on the fracture. The ingots up to 4 per cent. showed no colour on the fracture, but from 8 per cent. upwards the red colour was marked and increasing. All of the alloys containing up to 4 per cent. of copper could be hammered or rolled, the others not. The hardness, by Brinell's method, increased with the copper.

Thermal's measurements of the transformation points were not very satisfactory, especially in series A. In that series copper seems to raise Ar, and lower Ar_3. In B series, Ar and Ar_2 are both lowered as the amount of copper rises. The point at 975°—980° C. noticed in all the steels seems to mean separation of cementite. All, even the coppery part of 32 per cent. B, were magnetic when cold.—J. T. D.

Copper; Attempts at refining —— *with silicon or silicides.* F. Gloger. Metallurgie, 1906, **3**, 253; Chem.-Zeit., 1906, **30**, Rep., 208.

THE crude metal under experiment contained 97·25 per cent. of copper, with 1·774 per cent. of oxygen present in combination as protoxide. Silicon proved incapable of properly reducing this protoxide, but better results attended the use of manganese silicide, containing 19·77 per cent. of silicon, sufficient being added to react in the proportion of one molecule to four of cuprous oxide. The refined copper is very dense, free from oxide as well as from manganese and silicon, and the loss of metal is below 1 per cent.—chiefly in the slag. An excess of manganese silicide furnishes a manganese-copper alloy, but when the manganese does not exceed 1 per cent., its effect appears to be beneficial.—C. S.

Platinum, Corrosion of ——, *by sulphuric acid.* L. Quennessen. VII., page 695.

Tin in the Transvaal. Mining World, June 30, 1906. [T.R.]

THE first output of tin in the Transvaal has recently been declared. It is little more than a year since the discovery of the tin-bearing greisen on the Vlaklaagte farm, about 60 miles east of Pretoria. The tin lode in various forms has been traced over a considerable area. Within the last six months a 10-stamp mill and a Krupp ball mill have been installed to crush the greisen rock, and also a complete concentrating plant. The details of the output are as follows: Five stamps ran 20 days, crushing 486 tons, giving an output of 4·8 tons per day. The Krupp mill ran 24 days and 20 hours, crushing 201 tons, equivalent to an output of 8·1 tons per day. From the 687 tons, 16·8 tons of tin oxide were won, equal to a yield of 2·44 per cent. per ton of ore treated, and an extraction of 97·7 per cent. The cost of production was 45*s.* per ton, inclusive of 6*s.* for development, and 2*s.* for renewals.

Other tin areas are being discovered from time to time. The most recent discovery has been made on a farm belonging to the Transvaal Consolidated Land and Exploration Company, in the Bushveld area. Here good ore has been found in pockets, but prospecting so far has not shown the continuity or permanency of the deposit.

Copper deposit in Ontario. Eng. and Mining J., June 30, 1906. [T.R.]

A COPPER deposit has been recently discovered near Dean Lake station, on the Canadian Pacific Railway, in the township of Thompson, on the Leizert mine. The ore occurs at the point of contact between a trap dike, bearing inclusions of granite and quartzite, rounded and angular, and clay slate. Both the slate and the trap are impregnated, for a width at present unknown, with chalcopyrite, which is accompanied by calcite, and carries small amounts of silver and gold. The calcite appears to be in sufficient quantity to form a fusible mixture with the silicates of alumina and iron, and a smelting test already made demonstrates a fusible mixture. Mining machinery, consisting of boilers, air compressors, &c., has been installed upon the property, and development work is actively engaged in. The shaft sunk on the Leizert vein is now at a depth of 80 ft., and preparations are being made to drift in various directions. The vein is shown up by cross-cuts and pits, and can be followed for more than 1000 ft. As a self-fluxing copper ore the development is looked forward to with much interest.

ENGLISH PATENTS.

Welding iron or steel; Method of ——, with each other or with other metals, and fluxes employed for that purpose. E. L. Davies and W. G. Clark, Wessels Nek, Natal. Eng. Pat. 13,811, July 4, 1905.

THE parts to be welded are raised to "the oxidising temperature of iron," that is, about 800° to 1000° C., and are then plunged into a bath heated to the same temperature, and containing a mixture of silica and calcium carbonate in equal quantities. This flux dissolves the iron oxide formed, and the pieces are then withdrawn quickly, and welded in the ordinary way. (Compare Eng. Pat. 17,660 of 1904; this J., 1905, 1309; also Eng. Pat. 10,763 of 1899.)—A. G. L.

Furnaces; Impts. relating to ——. J. L. Babó and A. L. Louvrier, Honfleur, France. Eng. Pat. 26,076, Dec. 14, 1905. Under Int. Conv., Dec. 14, 1904.

THE furnace is intended for the extraction of zinc and lead from their ores by volatilisation. It consists of a scaphoid cavity, in the base of which is a slot through which the slag falls into the ash-pit below. An upward draught is maintained in the furnace by a blast or by suction, or by both, and the slot is cooled by circulation of air or water, in order to prevent its deformation.—A. S.

UNITED STATES PATENTS.

Furnace; Metallurgical ——. B. C. Lauth, Pittsburg, Pa. U.S. Pat. 823,057, June 12, 1906.

THE roof of the furnace, 4, has the shape shown in the figure,

and is provided near the top with a series of openings, 3, through which blast-nozzles, 5, discharge jets of air, under pressure, downwards into the furnace. The diameter of the openings is larger than that of the blast-nozzles, so that atmospheric air is drawn in by the jets of compressed air, and assists in promoting combustion on the hearth of the furnace.—A. S.

Roasting furnace [for ores]. A. W. Chase, New York. U.S. Pat. 823,393, June 12, 1906.

THE furnace consists of a casing in which several U-shaped troughs are disposed one above the other, each of them being provided with a spiral conveyor mounted on a hollow shaft, which is cooled internally with water. The conveyor-shafts are supported on bearings outside the furnace, and pass through circular openings in the furnace walls, these openings being closed by removable slotted plates which fit around the shafts. The furnace can be used as a muffle furnace or reverberatory furnace; in the former case the roasting-troughs are protected from the direct action of the fire by removable shelves, one situated below, and the other above the series of troughs. Means are provided for carrying the furnace gases around the troughs, and for supplying air to the roasting ore. Above the troughs, and resting on the cover of the furnace, there are placed a feed-hopper and conveyor, which also serves as a preliminary drier for the ore; the latter is here exposed to the gases escaping from the roasting-troughs, but is protected from the direct action of the fire.

—J. F. B.

Furnace; Tilting ——. J. C. Cromwell, Assignor to the Garrett-Cromwell Engineering Co., Cleveland, Ohio. U.S. Pat. 823,669, June 19, 1906.

IN each end of the framework of the furnace are mounted two "equalising-beams," on which two rollers are journalled. The rollers bear on a curved trackway, and means are provided for tilting the furnace. The rollers are mounted on the furnace in such a manner that they ride upon the curved trackway independent of the expansion of the furnace.—A. S.

Blast furnace. W. Kemp, Assignor to M. P. Freeman Tucson, Ariz. U.S. Pat. 824,485, June 26, 1906.

(*Continued from page* 644.)

(*A*.)—ELECTRO-CHEMISTRY.

Electrolysis of dilute solutions of acids and alkalis at low potentials. Dissolving of platinum at the anode by a direct current. G. Senter. Faraday Soc. Trans., July 2, 1906. [Advance proof.]

WHEN dilute solutions of sulphuric acid and of sodium hydroxide are subjected to electrolysis at a potential of 1·4 to 1·55 volts (*i.e.*, below the potential at which oxygen is evolved) and a current density of $1·2 \times 10^{-7}$ ampères per sq. cm., an oxidising substance is formed in small amount at the anode. This substance is very stable, especially in alkaline solution, and is not destroyed by boiling; it is shown not to be hydrogen peroxide. The rôle which the oxidising agent plays cannot be determined until some method is discovered of producing it in greater concentration. In the case of dilute acid small amounts of platinum are dissolved from the anode, which the author considers to be due to the solubility of an oxide, formed superficially upon the electrode.—R. S. H.

Nitric acid and nitrates; Direct synthesis of ——, *from their elements at the ordinary temperature.* M. Berthelot. VII., page 695.

Ozone; Use of —— *in quantitative analysis.* P. Jannasch and W. Gottschalk. XXIII., page 715.

Insulating material; Impts. in [electrical] ——. The British Thomson-Houston Co., London. From the General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 19,035, Sept. 20, 1905.

AN electrical insulating material, resistant to heat and moisture, is prepared by mixing a fibrous substance such as asbestos with suitable quantities of silica and a metal hydroxide, *e.g.*, calcium hydroxide, moulding the mixture into the desired form, and subsequently treating it with steam, under pressure, to produce a hydrous silicate in the interstices of the fibrous material.—A. S.

Ozonisers; Electrical —— C. A. Sahlström, Ottawa, Canada. Eng. Pat. 12,367, June 14, 1905. Under Int. Conv., June 21, 1904.

Ozone; Production of ——. Comp. Franç. de l'Ozone. Fr. Pat. 362,301, Jan. 10, 1906.

THE production of ozone from air by means of electric discharges is simplified, and rendered more economical by feeding one or both of the conductors with an alternating current with the aid of auxiliary condensers. A

Copper deposit in Ontario. Eng. and Mining J., June 30, 1906. [T.R.]

A COPPER deposit has been recently discovered near Dean Lake station, on the Canadian Pacific Railway, in the township of Thompson, on the Leizert mine. The ore occurs at the point of contact between a trap dike, bearing inclusions of granite and quartzite, rounded and angular, and clay slate. Both the slate and the trap are impregnated, for a width at present unknown, with chalcopyrite, which is accompanied by calcite, and carries small amounts of silver and gold. The calcite appears to be in sufficient quantity to form a fusible mixture with the silicates of alumina and iron, and a smelting test already made demonstrates a fusible mixture. Mining machinery, consisting of boilers, air compressors, &c., has been installed upon the property, and development work is actively engaged in. The shaft sunk on the Leizert vein is now at a depth of 80 ft., and preparations are being made to drift in various directions. The vein is shown up by cross-cuts and pits, and can be followed for more than 1000 ft. As a self-fluxing copper ore the development is looked forward to with much interest.

ENGLISH PATENTS.

Welding iron or steel; Method of ——, with each other or with other metals, and fluxes employed for that purpose. E. L. Davies and W. G. Clark, Wessels Nek, Natal. Eng. Pat. 13,811, July 4, 1905.

THE parts to be welded are raised to "the oxidising temperature of iron," that is, about 800° to 1000° C., and are then plunged into a bath heated to the same temperature, and containing a mixture of silica and calcium carbonate in equal quantities. This flux dissolves the iron oxide formed, and the pieces are then withdrawn quickly, and welded in the ordinary way. (Compare Eng. Pat. 17,660 of 1904; this J., 1905, 1309; also Eng. Pat. 10,763 of 1899.)—A. G. L.

Furnaces; Impts. relating to ——. J. L. Babó and A. L. Louvrier, Honfleur, France. Eng. Pat. 26,076, Dec. 14, 1905. Under Int. Conv., Dec. 14, 1904.

THE furnace is intended for the extraction of zinc and lead from their ores by volatilisation. It consists of a scaphoid cavity, in the base of which is a slot through which the slag falls into the ash-pit below. An upward draught is maintained in the furnace by a blast or by suction, or by both, and the slot is cooled by circulation of air or water, in order to prevent its deformation.—A. S.

UNITED STATES PATENTS.

Furnace; Metallurgical ——. B. C. Lauth, Pittsburg, Pa. U.S. Pat. 823,057, June 12, 1906.

THE roof of the furnace, 4, has the shape shown in the figure,

and is provided near the top with a series of openings, 3, through which blast-nozzles, 5, discharge jets of air, under pressure, downwards into the furnace. The diameter of the openings is larger than that of the blast-nozzles, so that atmospheric air is drawn in by the jets of compressed air, and assists in promoting combustion on the hearth of the furnace.—A. S.

Roasting furnace [for ores]. A. W. Chase, New York. U.S. Pat. 823,393, June 12, 1906.

THE furnace consists of a casing in which several U-shaped troughs are disposed one above the other, each of them being provided with a spiral conveyor mounted on a hollow shaft, which is cooled internally with water. The conveyor-shafts are supported on bearings outside the furnace, and pass through circular openings in the furnace walls, these openings being closed by removable slotted plates which fit around the shafts. The furnace can be used as a muffle furnace or reverberatory furnace; in the former case the roasting-troughs are protected from the direct action of the fire by removable shelves, one situated below, and the other above the series of troughs. Means are provided for carrying the furnace gases around the troughs, and for supplying air to the roasting ore. Above the troughs, and resting on the cover of the furnace, there are placed a feed-hopper and conveyor, which also serves as a preliminary drier for the ore; the latter is here exposed to the gases escaping from the roasting-troughs, but is protected from the direct action of the fire.

—J. F. B.

Furnace; Tilting ——. J. C. Cromwell, Assignor to the Garrett-Cromwell Engineering Co., Cleveland, Ohio. U.S. Pat. 823,669, June 19, 1906.

IN each end of the framework of the furnace are mounted two "equalising-beams," on which two rollers are journalled. The rollers bear on a curved trackway, and means are provided for tilting the furnace. The rollers are mounted on the furnace in such a manner that they ride upon the curved trackway independent of the expansion of the furnace.—A. S.

Blast furnace. W. Kemp, Assignor to M. P. Freeman Tucson, Ariz. U.S. Pat. 824,485, June 26, 1906.

FRENCH PATENT.

Cocoa-nuts or copra; Process of preserving ——. R. Marot. Fr. Pat. 362,369, Jan. 12, 1906.

THE flesh of the cocoa-nuts or copra is subjected to the action of a mixture of sulphur dioxide and air, which has been passed through an apparatus where it is submitted to an electrical discharge. The copra is treated preferably before exportation.—W. P. S.

GERMAN PATENT.

Liquids of different specific gravity, especially oil and water; Apparatus for the separation of ——. G. B. Bibolini and C. Baulino. Ger. Pat. 168,083, July 16, 1904.

THE separator comprises a number of superposed, closed chambers, communicating with one another by openings in the division walls. The mixture of liquids is supplied under pressure to the two lower chambers by a vertical pipe from an elevated reservoir. On the opposite side of the separator to the reservoir a vertical tube rises, through which the separated water rises to a height somewhat less than that of the supply reservoir, so that a continuous flow of the liquid in the lower chambers, in a horizontal or nearly horizontal direction, is caused. The oil which separates, collects in an upper chamber, and is removed from time to time.—A. S.

Paints and colours in which dry carbonate of lead or red lead is used; Regulations for the manufacture of ——. Home Office Circular. [T.R.]

THE following draft regulations apply to all factories and workshops in which dry carbonate of lead or red lead is used in the manufacture of paints and colours, provided as follows:—

(1) The Regulations shall not apply to factories and workshops in which paints and colours are manufactured not for sale but solely for use in the business of the occupier; or in which only the manufacture of artists' colours is carried on.

(2) Regulation 2, and so much of Regulation 3 as prevents the employment of a woman in manufacturing dry lead colour, shall not apply to the packing in parcels or kegs not exceeding 14 lb. in weight, unless and until so required by notice in writing from the Chief Inspector of Factories.

(3) Regulations 4, 5, 6, 11, and 12 shall not apply to factories or workshops in which the grinding of lead colours occupies less than three hours in any week, unless and until so required by notice in writing from the Chief Inspector of Factories.

Definitions for the purpose of these Regulations—

"Lead colour" means carbonate of lead and red lead, and any colour into which either of these substances enters.

"Lead process" means any process involving manipulation of materials containing lead.

PART I.—*Duties of Employers.*

1. No dry lead colour shall be placed in any hopper or shoot without an efficient exhaust draught and air guide so arranged as to draw the dust away from the worker as near as possible to the point of origin.

2. No dry lead colour shall be mixed, ground in oil, sifted, or otherwise manipulated so as to give rise to dust, save either—

(*a*) in an apparatus so closed as to prevent the escape of dust; or

(*b*) with an efficient exhaust draught and air guide so arranged as to carry away the dust as near as possible to the point of origin.

Provided that this regulation shall not apply to the immersion and manipulation of dry lead colour in water.

3. No woman, young person, or child shall be employed in mixing, grinding in oil, sifting, or otherwise manipulating dry lead colour.

4. Every person employed in a lead process shall be examined once in each calendar month by the certifying surgeon of the district, who shall have power to suspend from employment in any lead process.

5. No person after suspension in accordance with Regulation 4, shall be employed in any lead process without written sanction entered in the health register by the certifying surgeon.

6. A health register in a form approved by the Chief Inspector of Factories shall be kept and shall contain a list of all persons employed in any lead process. The certifying surgeon will enter therein the dates and results of his examinations of such persons with particulars of any directions given by him.

The health register shall be produced at any time when required by any of His Majesty's Inspectors of Factories or by the certifying surgeon.

7. Overalls shall be provided for all persons employed in lead processes; and shall be washed or renewed at least once every week.

8. The occupier shall provide and maintain for the use of all persons employed in lead processes—

(*a*) a cloak-room or other suitable place in which such persons can deposit clothing put off during working hours, and separate and suitable arrangements for the storage of overalls required by Regulation 7;

(*b*) a dining-room, unless all workers leave the factory during meal hours.

9. No person shall be allowed to introduce, keep, prepare, or partake of any food, drink (other than a medicine provided by the occupier and approved by the certifying surgeon), or tobacco in any room in which a lead process is carried on. Suitable provision shall be made for the deposit of food brought by persons employed.

10. The occupier shall provide and maintain in a cleanly state and in good repair for the use of persons employed in lead processes a lavatory (see this J., 1905, 1263).

Part II. relates to the duties of persons employed, as set forth in Part I.

It is also directed that no person shall, without the permission of the occupier or manager, interfere in any way with the means and appliances provided for the removal of dust or fumes and for the carrying out of these Regulations.

United States Patents.

White-lead; Apparatus for making ——. J. W. Bailey, New York, Assignor to United Lead Co., N.J. U.S. Pat. 823,097, June 12, 1906.

The apparatus consists of a number of corroding-chambers arranged side by side; these chambers are open at both ends, and are provided with a series of ledges one above the other, on which trays containing the comminuted lead are fed, so that when the trays are in position the open ends of the chambers are filled up. Externally to the corroding-chambers, there is a charging mechanism mounted on a carriage, which can serve all the corroding-chambers in turn. This mechanism contains tray-supporting and tray-feeding devices, which are vertically adjustable, to advance the trays into the corroding-chamber one above another. Molten lead is contained in a reservoir at the top of the machine, and is caused to flow through small openings, from a height, on each tray, whilst it is being pushed into the chamber. The tray which is being pushed into the chamber is caused to displace the tray containing the corroded lead which was already in the chamber, the latter tray being received on a washing device placed on the other side of the chamber. —J. F. B.

Paint or composition; Non-corrosive or anti-fouling ——. F. E. Dunnett, Assignor to Humidine, Ltd., London. U.S. Pat. 824,069, June 19, 1906.

See Fr. Pat. 358,592 of 1905; this J., 1906, 325.—T. F. B.

Pigments from antimony and arsenic, lithopone from white antimony or cerussite, yellow and red antimony sulphides, or antimony minium; Process of making ——. L. Brunet. Fr. Pat. 361,380, April 15, 1905.

See Eng. Pat. 16,490A of 1905; this J., 1906, 32.—T. F. B.

French Patents.

Antimony sulphide and oxysulphide; Production of colours and of metallic antimony from ——. C. Savigny and M. Douxami. Fr. Pat. 361,383, April 15, 1905.

Stibnite, or other sulphide rich in antimony, is powdered, intimately mixed with an alkali or alkali carbonate, and smelted in a cupola at a red heat for several hours. The mass is boiled with water, and the solution so obtained is precipitated with acid, avoiding all excess; the precipitate is separated, washed, and dried at 40°—50° C. Metallic antimony is often produced during the fusion, and settles to the bottom of the fused mass.—J. H. C.

Antimony oxysulphide [Pigment]; Production of orange-red ——. C. Savigny and M. Douxami. Fr. Pat. 361,384, April 15, 1905.

100 parts of antimony oxide and 36 to 37 parts of sodium carbonate are mixed together, and heated to redness for two or three hours. After cooling, the mass is finely powdered, mixed with sulphur or an alkali or alkaline-earth sulphide, and boiled with water. The solution thus obtained is treated with an acid, or with an acid solution of antimony chloride, and the orange-red or orange precipitate so formed is collected, and dried at 40°—50° C. The tint may be varied by varying the quantity of sulphur or of alkali sulphide employed. —J. H. C.

Lakes [from azo dyestuffs]; Production of red ——. Badische Anilin und Soda Fabrik. First addition, dated Jan. 18, 1906, to Fr. Pat. 297,330, Feb. 17, 1900. Under Int. Conv., Dec. 4, 1905.

See Eng. Pat. 82 of 1906; this J., 1906, 224.—T. F. B.

(B.)—RESINS, VARNISHES.

Turpentine production in India. Ch. of Comm. J., July, 1906. [T.R.]

The German Consul-General at Calcutta reports the probability of expansion in the production of turpentine in the pine forests of Kumaon Himalaya. In the year 1904—05, 62,000 trees were tapped in the Forest District of Naini Tal, and yielded 4,260 maunds of raw resin. More than 6,000 gallons of turpentine were manufactured, and also 3,300 maunds of colophony, for which there was a good demand. The cost of working amounted to 14,000 rupees, and the proceeds of the sale were nearly 30,000 rupees. Great hopes are entertained for the development of this new branch of industry, which is at present only in the initial stages, and experiments are being made to determine the influence exerted by the tapping upon the growth of the tree and upon the quality of the wood, as well as the best means of procuring a maximum yield of resin.

Varnish manufacture in the United States; Census of ——. Oil, Paint, and Drug. Rep., July 2, 1906. [T.R.]

The Director of the Census has announced the result of the census of varnishes for the calendar year ending December 31, 1904, forming a part of the Census of Manufactures of 1905.

The statistics show that there has been a substantial increase in this industry in the United States, as compared with the statistics of 1900, which covered the fiscal year ending May 31.

Comparative figures for 1905 and 1900 are shown in the following summary:—

English Patent.

Manila copal, sandarach, and like resinous substances; Process for rendering —— insoluble in oil, and especially suitable for use in the preparation of polishes. W. Baringer, Berlin. Eng. Pat. 3788, Feb. 15, 1906. Under Int. Conv., Feb. 25, 1905.

See Fr. Pat. 352,323 of 1905; this J., 1905, 234.—T. F. B.

(C.)—INDIA-RUBBER, Etc.

Asclepiadeæ; New rubber-producing —— from Madagascar. J. Constantin and I. Gallaud. Compt. rend., 1906, **142**, 1554—1556.

The two plants examined belonging to the *Asclepiadeæ* are distinguished by the names Kompitsé and Dangolora. The Kompitsé belongs to the group *Periplocæ*, and the authors propose the name *Kompitsia elastica*, as it represents a new genus. The Dangolora is allied to the genus *Marsdenia*. The latex of the two plants is mixed by the natives, and the rubber produced is known in Madagascar under the name Manomby.—F. Shdn.

Rubber-yielding plants; Experiments with —— in Dominica. J. Jones. West Indian Bull., 1906, **7**, 16—20.

Specimens of *Castilloa elastica* planted 13 years ago have thriven remarkably well, and have suffered little from storms. In 1904 they yielded 1 lb. per tree of high-class but somewhat dark rubber. Two distinct methods of tapping are found to give good results. In Fig. 1, the lines represent series of cuts made with the triangular tapping tool commonly used in Ceylon; this scheme of lines has considerable advantages over the older "herring-bone" scheme. In Fig. 2, the cuts are made with an ordinary chisel. The method, shown in the figures, of collecting the whole yield in one cup by means of the sheathing base of a leaf-stalk from a cabbage or other palm is strongly recommended. During tapping, the trunk of the rubber tree is sprayed with water to aid the disengagement of

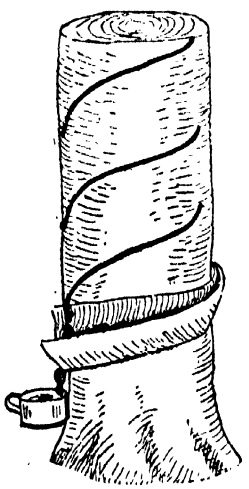

Fig. 1.

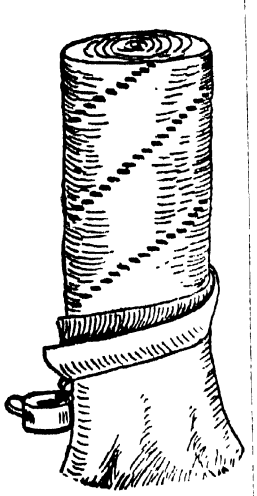

Fig. 2.

the latex. The rubber is separated without artificial coagulants.

Experiments with the Lagos rubber tree (*Funtumia elastica*) indicate that this tree does not lend itself to culture in Dominica so well as *Castilloa*.—W. A. C.

Rubber experiments in St. Lucia. J. C. Moore. West Indian Bull., 1906, **7**, 21—29.

Some *Castilloa elastica* trees planted 15 to 17 years ago are, on the whole, of poor growth, doubtless owing to the swampy ground. The total yield from nine trees amounts, so far, to 150 ozs. of biscuit and scrap rubber. From tapping experiments made on these trees it is inferred that the best yield is obtained if the tapping is done in the early morning on alternate days.—W. A. C.

India-rubber; Vulcanisation of Guayule ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 972.

Guayule rubber imported one year ago, and containing 13 per cent. of resin and 0·45 per cent. of water, was dried, and vulcanised under pressure for 45 minutes at 145° C. with rising percentages of sulphur. With less than 15 per cent. of sulphur, vulcanisation was found to be incomplete. From 15 to 50 per cent. the strength of the vulcanised rubber rose continuously, whilst the elasticity reached a maximum at 35 per cent. of sulphur.—W. A. C.

English Patent.

Plastic substances [Vulcanite and celluloid] used as bases in dental prothesis; Method of colouring ——. L. Eilertsen, Paris. Eng. Pat. 12,203, June 13, 1905.

The rubber or celluloid is coloured by the addition of ferric oxide, insoluble carmine, or alizarin and its derivatives, in conjunction with zinc oxide and sodium thiosulphate, or with zinc sulphite.—W. P. S.

United States Patents.

Rubber; Process of recovering — from rubber waste. W. A. Koeneman, Chicago, Ill. U.S. Pat. 823,053, June 12, 1906.

The rubber waste in a finely divided condition is boiled with a solution of a mineral acid containing "a halogen salt of the alkaline group, such as sodium or calcium chloride, without setting free in a gaseous state the chlorine, bromine, or iodine." The dissolved matters are removed, and the residual rubber is boiled with "a solution of an alkaline salt, such as soda or potash," with the addition of a substance having a preservative effect on vegetable matter, *e.g.*, boric acid or sodium borate, and of a "soluble gum," such as rosin or shellac. The product is afterwards treated with a "weak astringent solution" of an aluminium salt to precipitate any soluble compounds remaining from the previous operations, and is then washed, and dried.—A. S.

Rubber waste; Process of treating vulcanised —. W. A. Koeneman, Chicago, Ill. U.S. Pat. 823,054, June 12, 1906.

The finely-divided rubber waste is boiled first with an aqueous solution of sulphuric and hydrochloric acids, free from oxidising agents, and then with an alkaline solution, and is afterwards washed, and dried.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 647.)

Gelatin; Rendering —— insoluble by the atmospheric oxidation products of phenolic compounds. A. L. Lumière and A. Seyewetz. Collegium, 1906 [212], 205—207.

Phenolic compounds which possess photographic developing properties are not the only ones which will render gelatin insoluble (see this J., 1906, 496); certain other phenols, in alkaline solution, possess this property in a greater or less degree, the most active being gallic acid, tannin, phloroglucinol, β-naphthol, and dihydroxynaphthalene, in the order named. In absence of air, even in presence of alkali, none of the compounds tried produced insolubility of the gelatin. It appears thus that quinone is not the only substance which can render gelatin insoluble in absence of air, since its formation from resorcinol and the naphthols is highly improbable. Since tannin can only render gelatin insoluble in presence of air, and in alkaline solution, it would seem that oxygen plays an important part in tanning operations, which might explain the necessity for various processes to which hides must be subjected to ensure satisfactory tanning.

(*Continued from page* 647.)

Humus [in soils]; Formation of ——. S. Suzuki. Bull. Coll. Agric., Tokyo Imp. Univ., 1906, 7, 95—99.

FIVE Erlenmeyer flasks of about 1200 c.c. capacity were each charged with 100 grms. of dry, coarsely-powdered leaves of *Quercus serrata*, Thunb. (used as a litter in Japan), which had been previously moistened with 200 c.c. of water, and mixed with 1 grm. of humous soil. One flask served as a check; to the second was added 5 grms. of precipitated basic magnesium carbonate mixed with water to a fine milk, and 0·5 grm. of dipotassium-hydrogen phosphate; to the third, 5 grms. of precipitated calcium carbonate, 0·5 grm. of dipotassium phosphate, and 0·5 grm. of magnesium sulphate; and to the fourth, 5 grms. of precipitated calcium carbonate. The fifth flask received the same substances as the second; it was then sterilised, and the contents inoculated with the chocolate-coloured mycelium of a peculiar kind of penicillium, which produces a black substance when cultivated in koji-extract. The flasks were then allowed to stand, and from time to time about 10 litres of purified moistened air were sucked through each of the vessels, and then through caustic potash solution to absorb carbon dioxide. Test portions of the leaves were also examined under the microscope. The author states that the results show that humification of the leaves proceeds parallel with the development of carbon dioxide. Magnesium carbonate promotes the development of carbon dioxide, and, consequently, the humification process, whilst calcium carbonate retards it. The potassium phosphate had a favourable effect on the process.

In the fifth flask the amount of carbon dioxide produced was much less than (about one-third of) that produced in the control flask. The author proposes to continue the experiments until all the particles of leaves are transformed into black humus. After eleven months the colour of the leaves had become very dark, and the cohesion of the particles had been almost destroyed.—A. S.

Barley; Degree of stimulating action of manganese and iron salts on ——. T. Katayama. Bull. Coll. Agric., Tokyo Imp. Univ., 1906, 7, 91—93.

IT has been shown previously that the stimulating effect of manganese salts on oats, upland rice, barley, and wheat is not so great as on leguminous plants. An application of 0·015 per cent. of manganous sulphate (calculated on the weight of the soil) caused an increase of 50 per cent. in the yield of straw, and 25 per cent. in that of seeds, in the case of the pea, whereas the same quantity (and also an increased quantity of 0·04 per cent.) caused a total increase in the yield of only about 10 per cent. in the case of cereals. Further experiments on barley with manganous sulphate and ferrous sulphate, and also with mixtures of the two salts, have now shown that a mixture of 0·01 per cent. each of crystallised ferrous sulphate and manganous sulphate produces a moderate increase of yield, *viz.*, 6·21 per cent. more straw and 7·21 per cent. more seeds, but that greater quantities of the salts caused a general decrease of yield.—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 648.)

Steffen's [sugar] extraction process. Scharffenberg. Z. Ver. deutsch. Zuckerind., 1906, 604—609.

IN this process the beetroot slices fall directly from the slicing machine into the hot sugar juice contained in the so-called steeping trough. The latter is perforated for one-third of its length, and the perforated portion is enclosed in a metal box. The beet slices are carried through the trough by a transport belt. The juice flows through the perforations into the outer box, and thence into a centrifugal pump, whence it passes through a heating apparatus, and then back to the other end of the trough. The temperature of the juice in the trough is kept at 95°—100° C. The beetroot slices remain in the trough for about three minutes. At the end of the trough the slices are removed by an ascending spiral, at the top of which they are pressed, the juice being returned to the trough. Hot water is added as required to the juice circulating through the trough, the sweet water from the pressed mud being used for this purpose; the excess juice runs from the trough through an overflow tap, and is then treated in the usual way. The pressed slices are sprayed with diluted syrup; in very good years the whole of the syrup may be used in this way. The slices are then again pressed, the pressed juice being returned to the trough. Owing to the high temperature (at least 80° C.) at which the slices are pressed, a cake is obtained which contains 30—35 per cent. of dry substance and 10—12 per cent. of sugar. After drying, it contains 30—35 per cent. of sugar, and is known as "Zuckerschnitzel." The yield of refined sugar obtained by this method is less than that obtained by the diffusion method; the total yield, however (*i.e.*, including the sugar in the "Zuckerschnitzel"), is considerably greater; the value of the products from 50 kilos. of beetroot (average of three years) obtained by the steeping process was 1·543 marks, and by the diffusion process 1·403 marks. Moreover, the working expenses are less by the former method. The "Zuckerschnitzel" finds a ready sale as a cattle food.—L. E.

Beetroot juice; Chemical purification of ——. K. C. Neumann. Z. Zuckerind. Böhm., 1906, 30, 477—479.

FOR the decolorisation of beetroot juice crystallised hyposulphites (hydrosulphites) ($R_2S_2O_4+2H_2O$) and double salts of hyposulphites have been proposed, but they readily undergo decomposition. Anhydrous sodium hyposulphite is much more stable, but its complicated method of preparation renders it costly. The product formed by the reaction of sodium hyposulphite and formaldehyde according to the equation

$$Na_2S_2O_4+2CH_2O+H_2O=$$
$$(NaHSO_2\cdot CH_2O)+(NaHSO_2\cdot CH_2O),$$

and which consists, therefore, of sodium bisulphite formaldehyde and sodium sulphoxylate formaldehyde, is both stable and inexpensive, and it possesses a very great decolorising power. The results obtained so far with this substance have been very encouraging.

Twenty hectolitres of thin juice treated with ½ litre

of the preparation (sp. gr. 1·26), and 20 hectolitres of thick juice treated with ½ litre, were completely decolorised. Twenty hectolitres of green syrup were considerably clarified by 1 litre of the preparation. Owing to the small quantity of the preparation required, the juice is not injuriously affected, and no invert sugar is formed.—L. E.

Beetroot juice; Chemical purification of ——. V. Halousek. Z. Zuckerind. Böhm., 1906, **30**, 479—480.

THE "double compound of sodium hyposulphite and formaldehyde" (see preceding abstract) has been used successfully in a sugar factory at Radotin. Twenty-two hectolitres of green syrup (32° B.) were treated with ½ litre of the hyposulphite preparation of density 1·26. The clarification was better than that obtained with sulphur, whilst the yield and colour of the sugar were quite as good.—L. E.

Beetroot juice; Chemical purification of ——. R. Mandelik. Z. Zuckerind. Böhm., 1906, **30**, 480—481.

THE author has used anhydrous sodium hyposulphite (hydrosulphite) in the treatment of thick juice, and has compared its decolorising effect with that of aluminium sulphite. The former was a much stronger decolorising agent. Similar results were obtained with refined sugar juice.—L. E.

Sugar juice; Saturation of —— with sulphur dioxide. Von der Ohe. Z. Ver. deutsch. Zuckerind., 1906, 588—592.

THE author is of opinion that sugar juice should be subjected to three saturations, and not two only, as is done in some factories. The use of sulphur dioxide, however, for saturation has one disadvantage. A portion of the calcium bisulphite formed by decomposition of organic calcium salts, separates in the evaporating pans, thus producing incrustation of the latter. This annoyance may be removed by saturating the thin juice with carbonic acid instead of sulphur dioxide. Since sulphur dioxide is a valuable clarifying agent, however, the author recommends the saturation of the thick juice, subsequently obtained, with sulphur dioxide. Owing to the slimy precipitate formed in this last operation, filtration is somewhat difficult, but the author considers that the more exact saturation thus obtained, and the prevention of incrustation in the evaporation of thin juice, outweigh this disadvantage. In the discussion which followed, Preissler disputed the formation of incrustation in the evaporating pans when the thin juice has been previously treated with sulphur dioxide, and remarked also that the saturation of the thin juice may be so regulated that the alkalinity of the thick juice may be of any desired degree.—L. E.

Thick [sugar] juice sludge; Periodic occurrence of copper in ——. Bülow. Z. Ver. deutsch. Zuckerind., 1906, 601—604.

AN analysis of the sludge collected on the thick juice filter showed that on two successive Mondays it contained 1·42 and 1·17 per cent. of copper respectively, while on the Wednesday of the second week it contained 0·006 per cent. only. The thick juice pan was washed every Sunday with sodium carbonate and hydrochloric acid, and then carefully rinsed with water. The copper was present in the mud in the cuprous state. The copper must have come from the brass tubes of the evaporating pan, since this was the only part of the apparatus containing copper. By acting on a strip of polished brass with thin juice, the author shows that the latter is capable of dissolving out copper from the brass to a considerable extent, and sufficiently so, to account for the amount of copper found in the thick juice mud. In conclusion, the author considers that the following is the true explanation: The boiling juice evolves an appreciable quantity of ammonia, which attacks the freshly cleaned tubes, and the ammoniacal copper compounds thus formed are then reduced either by reducing substances in the juice or by salts of sulphurous acid. During the week the tubes again become coated with lime, thereby being protected from the action of the juice. Hence, by the middle of the week, traces only of copper are found in the thick juice mud.—L. E.

Mother-liquors from first products [sugar] by Raabe's method; Treatment of ——. Stutzer. Z. Ver. deutsch. Zuckerind., 1906, 610—614.

THE mother-liquor from the first products (purity about 73—78) is heated by a current of steam to 90° C., and diluted at the same time to 60°—65° Brix. The juice is then filtered through a Neumann sand filter, and subsequently saturated in a saturator (Raabe's system). The alkalinity of the syrup should not be less than 0·04 nor greater than 0·06 per cent.; otherwise the subsequent boiling is rendered difficult. After saturation, the syrup is filtered through doubled, not too fine, cotton cloth. The clear filtrate, which is ready for boiling, now passes into the reservoir, which must be provided with steam tubes in order that the syrup may be again heated, and diluted if necessary. The syrup that passes into the vacuum boiler from the reservoir should be at a temperature of 90° C., and have a density of 60°—65° Brix; it is heated with steam at a pressure of 1—1·5 atmospheres; the steam pressure is reduced to 0·3—0·5 atmosphere when the syrup has granulated sufficiently; it should be raised again to 1—1·5 atmospheres during the boiling off. The steam pressure is regulated by means of a regulator devised by Poensgen. The boiling temperature is maintained at 75° C., and must not fall below this. The juice is boiled for 30 to 36 hours; the massecuite is boiled down until its water content is 8—9 per cent. During the boiling off, the melt is raised to a temperature of 80° C., and is then run off as quickly as possible. Each boiling pan must either be provided with a separate condenser, or if only a central condenser is used, the connection between it and each pan must be so arranged that the vacuum may be maintained in each pan independently of the others. The melt which has run off from the boiling pan is now stirred. Under normal conditions the melt must be stirred for 72 hours in order to attain a quotient of 60—61 in the final molasses. The melt should be stirred for two hours, and then allowed to stand for one hour, and so on alternately. Five per cent. of molasses (diluted to 55°—60° Brix) is added to the melt one hour before the latter is centrifugalised. At the beginning of the last operation the melt must be at a temperature of 50° C.

The granulated sugar obtained by this method contains comparatively little mineral matter, and possesses a "rendement" of 88—92.—L. E.

Mucilage-forming bacteria observed in the course of sugar manufacture; New ——. Gonnermann. Z. Ver. deutsch. Zuckerind., 1906, 600—601.

THE author submitted the mucilaginous matter found on the plates of some pans used for the second saturation of sugar juice, to bacteriological examination. From this source he isolated three, and from the air of the room in which the pans were placed, two different varieties of bacteria, which formed mucilage-like substances in all kinds of nutrient media. These bacteria are new varieties. The formation of mucilage was specially noticeable with cultivation on sugar beet. The author concludes that the production of the mucilage is caused by the bacteria which it contains, and that the latter owe their existence to the very great resisting power of their spores, which are capable of withstanding the action of the hot acidified water, used for cleaning the pans, and also the subsequent varnishing. After the varnish has been worn away, the spores begin to develop, and when the juice has cooled to 37° C. mucilage is produced.—L. E.

Melezitose and turanose. G. Tanret. Comptes rend., 1906, **142**, 1424—1426.

MELEZITOSE is a trisaccharide composed, not, as has been thought hitherto, of three dextrose residues, but of two dextrose residues and one lævulose residue. On regulated hydrolysis, melezitose yields dextrose and turanose. *Turanose* is best prepared by heating melezitose with 20 per cent. acetic acid for two hours on a boiling water-bath. The acid is extracted by ether, and the mixture of sugars

is treated with yeast. In this way the dextrose can be completely fermented, whilst the turanose is but little attacked. Turanose, when purified by means of alcohol, is obtained in the form of hygroscopic, non-crystalline granules which retain alcohol, and have the composition $C_{12}H_{22}O_{11},\frac{1}{2}C_2H_6O$. This compound melts at 60°—65° C., and loses its alcohol when dried at 100° C. The rotatory power of the dried turanose in 5—10 per cent. solutions is $[\alpha]_D = +71{\cdot}8$; it shows no bi-rotation. The reducing power is equal to 60 per cent. of that of dextrose. Turanose is not hydrolysed by any of the ordinary enzymes, and is consumed very slowly by yeast. Hydrolysis by acids yields a mixture of equal proportions of dextrose and lævulose, but it cannot be effected completely without the destruction of some of the lævulose.—J. F. B.

FRENCH PATENTS.

Carbonating apparatus for sugar works. E. L. Tanchon. Fr. Pat. 362,470, Jan. 17, 1906.

THE sugar syrup, treated previously with lime, is pumped into a cylindrical vessel, the upper part of which is surrounded by a second cylinder. When the inner cylinder is about one half filled, the syrup flows through pipes into the lower part of the outer cylinder. The gas is passed down a central pipe to the bottom of the inner cylinder, the end of the pipe being divided into a number of branches which are surrounded by an inverted dome. The gas rises through the syrup, and is conducted from the top of the cylinder through pipes to the bottom of the outer cylinder. A chimney is provided at the top of the outer cylinder for the escape of the excess of gas, and the treated syrup leaves this cylinder by a pipe provided for the purpose.—W. P. S.

Beet-sugar; Process for making —— without formation of by-products. O. W. Luther. Fr. Pat. 362,492, Jan. 18, 1906. Under Int. Conv., Jan. 19, 1905.

Sugar production of Russia. For. Off. Ann. Series No. 3653. [T.R.]

THE campaign of 1905—06, with 277 factories in operation, showed a production of 875,717 tons of sugar, or 36,989 tons more than was produced by the previous campaign of 1904—05. The stock of sugar on hand from the previous campaign is 172,968 tons, comprising 32,073 tons of the inviolable reserve, 112,344 tons of finished sugar and 28,551 tons of products calculated as white crystals. There will thus be an available supply of 1,048,685 tons, which is 80,347 tons under the "normal profitable production" stipulated by the Government as the quantity for the campaign of 1905—06. 870,967 tons are destined for the supply of the home market.

The actual yielding area was 1,324,540 acres, which gave a yield of roots of 7,780,287 tons or 117½ cwts. to the acre, an increase in area of 141,224 acres and in yield of roots of 391,545 tons compared with 1904.

The quantity of sugar supplied for consumption was 542,003 tons of refined and 292,429 tons of white crystals. The quantity of sugar exported by Russia in 1905 was 97,234 tons, as against 170,243 tons in 1904, and 236,673 tons in 1903.

XVII.—BREWING, WINES, SPIRITS, Etc.

(*Continued from page* 651.)

Malt; Regulation of the moisture and the colour of ——, *on the kiln.* K. Guttwein. Woch. f. Brau., 1906, **23**, 296.

THE rate of the removal of the water from the malt on the kiln, and the temperature at which the evaporation is effected, are factors of the highest importance in determining the colour and aroma of the finished product. The author describes an arrangement by which the attendant is able to control exactly the quantity of water remaining in the malt at every stage of the process, and to regulate the temperature and draught accordingly. This arrangement consists of a ventilating fan, the speed of which can be varied, and of a lever balance, placed under the drying hurdle of the kiln, by means of which the weight of the hurdle and its contents can be ascertained from time to time. The percentage of moisture in the green malt is determined by some rapid process, such as Hoffman's, at the time of loading the kiln, the total weight of the green malt is ascertained, and from these data a table is constructed, showing the temperatures and weights which are to be followed by the attendant at definite intervals of time, according to the course of treatment it is desired to adopt.—J. F. B.

Malt extracts; Some new properties of ——. L. Maquenne and E. Roux. Comptes rend., 1906, **142**, 1387—1392.

CONTINUING their previous investigations (this J., 1906, 601), the authors have found that filtered malt infusions, prepared by one hour's contact between malt and water, undergo an increase of activity on storage similar to that produced by the limited addition of acid. This property of auto-stimulation appears to be associated with the action of the proteolytic enzymes. When digested at 56° C., the activity of the infusion increases to a maximum in five hours, and then decreases; at 50° C., however, the increase continues for a much longer time before it is stopped by the destructive action of the heat, whilst at 15° C. the auto-stimulation steadily increases for several days. On the other hand, if the malt extract be previously stimulated by the addition of acid, it undergoes a continuous loss of activity on digestion at 50° C. The maximum stimulation is obtained by digesting the malt extract in the ordinary condition at 15° C for several days, until a considerable auto-intensification has taken place, and then adding acid to the "optimum" point of alkalinity. An extract so treated yielded 103·4 per cent. of maltose in 24 hours. The "optimum" alkalinity is the same for extracts which have undergone auto-stimulation as for fresh extracts, *viz.*, about 8 mgrms. of potash per litre of 2 per cent. mash. In the case of extracts which have been digested at 50° C. a further stimulation on the addition of acid is only obtainable when the digestion has not been too prolonged, since the heat partially destroys the zymogen on which the acid acts. From a consideration of the experimental facts, it would appear that the stimulation of malt extracts by age or acids relates only to the

saccharification of the dextrins derived from the amylopectin (see this J., 1905, 650). Amylocellulose, freed from amylopectin, is completely converted into maltose almost instantaneously by ordinary malt extracts. It is suggested, therefore, that a special diastase is required for the conversion into maltose of the amylopectin or "residual dextrins," that this special diastase exists in malt extract only in the form of zymogen, and that it is liberated from this zymogen, either immediately by acids, or gradually by digestion.—J. F. B.

Respiratory enzymes in plants; The work of ——. W. Palladin. Z. physiol. Chem., 1905, **47**, 407—451; Woch. f. Brau., 1906, **23**, 317.

The author concludes that the carbon dioxide evolved by the respiration of plants has various origins. The carbon dioxide evolved under anaërobic conditions is the result of the activity of the carbonases. That which is evolved from the uninjured frozen plants, when the atmosphere of hydrogen is replaced by air, without the addition of any reagents, is the product of the activity of the oxydases. That which comes off after the addition of pyrogallol is the product of the activity of the oxygenases. The oxygenase-carbon dioxide, *plus* that produced after the addition of hydrogen peroxide, represents the product of the activity of the peroxydases. The respiratory energy of plants depends on their contents of nucleoproteids. When the plants are surrounded by water instead of gas, the production of carbon dioxide falls off very considerably, owing probably to extraction of enzymes, co-enzymes, and nutrients. Plant germs developed in a decoction of wheat-embryos, evolve far more carbon dioxide than those grown in water, but sugar solutions have the same effect, so that the question whether the stimulus is due to the presence of a co-enzyme in the wheat-decoction, or merely to that of nutrients, is left undecided.—J. F. B.

Yeasts; Anomalus —— [Saccharomyces anomalus], and a new species, Willia Wichmanni. H. Zikes. Woch. f. Brau., 1906, **23**, 318.

The author describes a new species of anomalus yeasts [*Saccharomyces anomalus*], which he has isolated from a soil near Vienna, and to which he gives the name of *Willia Wichmanni*. This species differs from others of this genous in that its growths are not compact, flat, and dry, adhering firmly to the sub-stratum, but form a raised, slimy layer resembling the colonies of certain wort-bacteria. The sedimentary cells grown in wort are 3—5 μ in length and 3 μ in width; the film cells are elongated from 6 up to 40 μ. The temperature limits are 5°—32°C., with an optimum at 22° C. The cells are strongly refractive, stain well with Methyl Green, and occur in single elements, very rarely in pairs. The spores are pileate, 2 μ in height, and generally occur in the cells in twos, but sometimes in threes and fours. They germinate on gypsum blocks most readily at 21° C. The strongly mucous nature of the cell walls is made evident by staining with acetic acid and aniline-Gentian Violet solution; the sheath forms a zone about 3 μ in width. This variety consumes only dextrose and lævulose. The author enumerates the other species of *Saccharomyces anomalus* hitherto described, and gives a table setting forth comparatively the various characteristics of the eight best-known species.—J. F. B.

Saccharomyces ellipsoideus I. Hansen, The division of the cell-nucleus of —— during budding. F. Fuhrmann. Centr. Bakt. (Abth. 2), **15**, 709—717; Woch f. Brau., 1906, **23**, 318—319.

The observations of the author on the process of the division of the nucleus in *Saccharomyces ellipsoideus I.* agree on the whole with those of Swellengrebel on pressed yeast (see preceding abstract). The author prepared his specimens in a somewhat different manner, preferring to cut sections of the yeast cells fixed in a substratum. For this purpose a quantity of the culture was spread on an object-glass in a layer of 1 mm. in thickness, and egg-albumin was poured over the surface, the preparation then being fixed in a suitable solution. The films were then washed in running water for several hours, and gradually hardened by means of solutions of alcohol of increasing strengths. The films were embedded in paraffin, and sections were cut. Since a large number of the yeast cells were cut through, the preparations absorbed the stains very freely; the best results were got by staining with an iron mordant, followed by hæmatoxylin; other characters were brought out by alizarin mordanted with chrome. The results showed that *S. ellipsoideus I.* follows the type of a complete caryokinesis, the phenomena being similar to those described above by Swellengrebel. The author failed to confirm Hirschbruch's observations of a bisexualism and of a self-fertilisation of the yeast.—J. F. B.

Yeast cells; Influence of highly concentrated sugar solutions on the function of the endotryptase in dead ——. J. Gromow. Z. physiol. Chem., 1906, **48**, 87; Woch. f. Brau., 1906, **23**, 317.

The author had observed that solutions of cane sugar exerted a retarding influence, increasing with their concentrations, on the auto-digestion of the albuminoids in dead yeast cells. Further experiments, made with 60, 80, and 100 per cent. concentrations of cane sugar, and with 60 per cent. solutions of dextrose, showed either a complete inhibition of the auto-digestion or even a slight synthesis of albumin. This synthesis of albumin, though scarcely exceeding the limits of experimental errors, points to the possibility of synthetic enzymatic action by the reversal of the activity of the yeast endotryptase. Zaleski had arrived at an analogous conclusion in his study of the enzymatic synthesis of albumin in ripening seeds.—J. F. B.

Yeast; Absorption of dyestuffs and metallic salts by ——. T. Bokorny. Allgem. Brauer- u. Hopfen-Z., 1905; Woch. f. Brau., 1906, **23**, 299.

Yeast is rapidly stained by a solution of Methylene Blue at a concentration of one per 10,000, and the cells retain their power of budding and fermenting. In the budding chains coloured and uncoloured cells can be detected side by side. A solution of Methyl Violet containing one part per 10,000 also stains yeast, but the cells are killed at the same time. Yeast has the property of absorbing salts of the heavy metals from their solutions. Experiments with silver nitrate at concentrations ranging from one per 10,000 to one per 1,000,000 showed that the silver was deposited in the yeast after contact for several hours, whilst the bath was exhausted of silver. Copper salts were absorbed in the same manner, but mercuric chloride gave negative results. Yeast behaves in these respects similarly to aquatic plants which also possess specific powers of absorbing certain metals from dilute solutions. The process appears to depend on the formation of insoluble metallic compounds in the cells with the continuous diffusion of further quantities of the salt into the organism.—J. F. B.

Lactic acid fermentation; Influence of small quantities of metals on ——. E. Richet. Comptes rend. Soc. Biol., 1905, **60**, 455—456; Woch. f. Brau., 1906, **23**, 317.

The author has observed that minute quantities of barium, platinum, cobalt, manganese, vanadium, and the salts of spring waters exert a slight stimulating influence on the lactic acid fermentation.—J. F. B.

Beer pediococci; Occurrence of ——. N. H. Claussen. Z. ges. Brauw., 1906, **29**, 397—400.

The existence of several well-defined kinds of beer pediococci is generally doubted, and the varying disease symptoms observed in beer infected with these organisms is, as a rule, ascribed to a variation in the degree of virulence of the latter. The author shows experimentally that the virulence of the pediococci is not affected by the nature of the yeast used in fermentation, nor by the quality of the wort, nor by the method of fermentation; he considers that the varying effects of pediococci on beer is due, not to different degrees of virulence of these organisms, but to their specifically different characters. In another series of experiments the author endeavoured to trace the source of pediococci infection. The air of a dusty street

was found to be free from these organisms, both in March and August. Typical beer pediococci were found, however, in the air of a fermenting cellar in March. Out of 25 samples of barley and malt, two were found to contain beer pediococci. Hence, in comparison with other organisms, beer pediococci very seldom occur in nature. Of the two organisms, one, obtained from barley, appeared to be a *Pediococcus damnosus*; the other, obtained from green malt, showed the same properties as *Pediococcus perniciosus*. The latter organism affects beer injuriously, without any preliminary acclimatisation. Hence it is possible for a naturally occurring beer pediococcus to exert an injurious action directly it is placed in fermenting wort, and therefore the theory of acclimatisation must be abandoned.—L. E.

"Brettanomyces"; Occurrence of —— in American lager beer. N. H. Claussen. Amer. Brewers' Rev., 1905, **19**, 525; Z. ges. Brauw., 1906, **29**, 407—408.

So far as experience goes, in the presence of "*Brettanomyces*," a pure and agreeable taste is only obtained with top fermentation and completely fermented beer. Hence the organism is quite useless for primary fermentation. H. Schiönning has isolated *Brettanomyces* from Danish beer. It was necessary, however, to subject the beer to a preliminary treatment, adapted to the properties of the organism, in order that a considerable growth of the latter might occur. The author has also found *Brettanomyces* in American lager beer, and is of the opinion that this organism occurs fairly frequently in lager beer. Hence, cells of *Brettanomyces*, capable of development, occur fairly often in beers of most various kinds; they are only of real importance, however, in the case of certain English beers. Since the *Brettanomyces* occur occasionally in beers of very different kinds, there is probably a permanent natural source of infection existing here and there, from which, according to the time of year and local conditions, small numbers of organisms are introduced into the brewery; these organisms are retarded in development, however, or altogether suppressed (stage 1). If, however, exceptionally favourable conditions obtain in the brewery, the organism is enabled to produce its specific effect, accompanied by vigorous development, and an acute form of the characteristic disease occurs (stage 2). If the conditions in the brewery are frequently, or even permanently favourable to growth, the disease passes into the third stage. The organism increases enormously, the fresh infecting material, in a very vigorous state, spreads continuously, independently of all external conditions, and the disease has now become chronic. The *Brettanomyces*, in English breweries, present a typical example of such an infection in the third stage.—L. E.

Beer: Peculiar sediment in pasteurised ——. N. H. Claussen. Amer. Brewers' Rev., 1905, **19**, 578; Z. ges. Brauw., 1906, **29**. 407.

THE author has examined the sediment of a pasteurised beer, consisting of relatively large, bulky flocks, more or less dark in colour. Microscopic examination showed that the sediment consisted of unorganised matter, in which crystals, cork cells, and sundry indefinite particles, besides a moderately large number of bacteria, were embedded. In addition, diatoms and green algæ were found in the flocks. For soaking the bottles, the brewery used lye, prepared with water from Lake Michigan, and the bottles were afterwards rinsed with water from the same source, and then with filtered water. The water from the lake was found to contain exactly the same organisms as were present in the bottles. In order to determine the cause of the formation of the sediment, various samples of the lake water were placed in open bottles in the laboratory. All the samples showed a considerable quantity of diatoms and green algæ, and, in addition, more or less numerous protozoa and bacteria developed. Amongst the latter a rod-shaped organism was observed, which formed a very bulky mucilage. In a bottle rinsed out with this water, and then filled with beer, and pasteurised, flocks were formed, quite similar to those contained in the bottles originally examined. The same result was obtained when 1 c.c. of the water was added directly to the beer in the bot before pasteurisation. The greater the amount of bacte mucilage in the water, the more abundant was the forn tion of flocks in the pasteurised beer.—L. E.

Wine from the loquat fruit. T. Takahashi. Bull. C Agric., Tokyo Imp. Univ., 1906, **7**, 111—112.

THE fruit of the loquat, *Eriobotrya japonica*, Lindl., a yellow colour, "very fragrant flavour," and sweet tas it is used as a foodstuff. The fruits contain 73·57 cent. of water and 26·43 per cent. of dry matter, compo of 13·72 per cent. of seeds and 12·71 per cent. of fle The must has a density of 12°—13° B. at 17·5° C., contains: dextrose, 7·3; pentosans, 0·395; pec 3·266; citric acid, 0·284; malic acid, 0·070; and 0·544 per cent. On adding 15 per cent. of cane sugar the must, and allowing it to ferment, a wine rosembl "Tokayer" in taste and flavour was obtained. By mentation of 108 hectolitres of the juice with a p culture of wine yeast, a wine having the sp. gr. 1·02 and of the following composition, was obtained: alcol 7·130; glycerol, 0·0873; volatile acids (as acetic ac 0·145; non-volatile acids (as citric acid), 0·437; su (dextrose), 0·284; extractive matter, 3·116; and 0·490 per cent.—A. S.

Amylocelluloses [Insoluble amyloses] in natural starch Determination of the ——. J. Wolff. XXIII., p 716.

Colouring matters from molasses, vinasse, &c. Wichar IV., page 687.

Alcohol Bill; Industrial —— in the United States. Paint. and Drug Rep. [T.R.]

ON May 24th the Senate passed unanimously the providing for the freeing from taxation, after Jan. 1, 19 of denatured alcohol used for industrial purposes: Bill has since received the President's signature. Foll ing is the text:—

"Sec. 1. Be it enacted, &c., that from and after th months from the passage of this Act domestic alcohol such degree of proof as may be prescribed by the Comm sioner of Internal Revenue and approved by the Secret of the Treasury, may be withdrawn from bond without payment of internal revenue tax, for use in the arts industries, and for fuel, light, and power, provided alcohol shall have been mixed in the presence and un the direction of an authorised government officer bef withdrawal from the bonded warehouse, with denatur material suitable to the use for which the alcohol is wi drawn, but which destroys its character as a bever and renders it unfit for liquid medicinal purposes.

"The character and quantity of the said denatur material and the conditions upon which said alcohol n be withdrawn free of tax shall be prescribed by the C missioner of Internal Revenue, who shall, with the proval of the Secretary of the Treasury, make all necess regulations for carrying into effect the provisions of Act.

"Sec. 2. That any person who uses alcohol withdra from bond under the provisions of Section 1 of this for manufacturing any beverage or liquid medici preparation, or knowingly sells any beverage or liq medicinal preparation made in whole or in part from a alcohol, or knowingly violates any of the provisions this Act, or who shall recover or attempt to recover redistillation or by any other process or means any alco rendered unfit for beverage or liquid medicinal purpo under the provisions of this Act, or who knowingly u sells, or conceals alcohol so recovered or redistilled, sh on conviction of each offence, be fined not more th $5,000 or be imprisoned for not more than five years, both; provided that manufacturers employing processes which alcohol, used free of tax under the provision of t Act, is expressed or evaporated from the articles ma factured, shall be permitted to recover such alcohol and have such alcohol restored to a condition suitable sol for re-use in manufacturing processes under such re lations as the Commissioner of Internal Revenue, with approval of the Secretary of the Treasury, shall prescri

"Sec. 3. That for the employment of such additional force of chemists, Internal Revenue agents, inspectors, deputy collectors, clerks, labourers, and other assistants as the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, may deem proper and necessary to the prompt and efficient operation and enforcement of this law, and for the purchase of locks, seals, weighing beams, gauging instruments, and for all necessary expenses incident to the proper execution of this law, the sum of $250,000, or so much thereof as may be required, is hereby appropriated out of any money in the Treasury not otherwise appropriated.

"For a period of two years from and after the passage of this Act, the force authorised by this section of this Act shall be appointed by the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, and without compliance with the conditions prescribed by the Act entitled 'An Act to regulate and improve the Civil Service,' approved January 16, 1883, and amendments thereof, and with such compensation as the Commissioner of Internal Revenue may fix, with the approval of the Secretary of the Treasury."

ENGLISH PATENT.

Beer and the like; Apparatus for cooling and carbonating ——. L. Chew and H. J. West and Co., London. Eng. Pat. 20,086, Oct. 4, 1905.

THE invention relates to improvements in the cooling and carbonating cylinders employed in the production of the beer described in Eng. Pat. 17,951 of 1902 (this J., 1903, 223). Cross tubes are now arranged through the cylinder in such a manner that there is a natural circulation of the cooling liquid through them from one part of the jacket to another. The ends of the cylinder may also be provided with cooling jackets.—W. P. S.

FRENCH PATENT.

Alimentary product [Albuminoid containing metal salts]; Preparation of an —— from yeast. G. Jacquemin. Fr. Pat. 361,356, April 12, 1905. XVIII.*A.*, next column.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 652.)

(*A.*)—FOODS.

White of egg; Phosphorus content of ——. K. Kaas. Monatsh. Chem., 1906, **27**, 403—409.

THE author quotes analyses to show that white of egg and crystallised ovum albumin contain phosphorus in varying amounts. Thus the white of a fresh egg contained 0·155 per cent., whilst that of an egg, from the same fowl, which had been kept for a month contained 0·228 per cent. Crystallised preparations obtained either by the Hammarsten or Hopkins-Pinkus methods from white of egg contained as much as 3·0 per cent. of phosphorus. It is suggested that the phosphorus is not present as an impurity, but forms an essential constituent of the ovum albumin.—E. F. A.

Milk: A condensed vegetable ——. T. Katayama. Bull. Coll. Agric., Tokyo Imp. Univ., 1906, **7**, 113—115.

A LIQUID closely resembling cows' milk is obtained by soaking soy-beans in water, crushing them, and boiling with water. It has the following average composition: Water, 92·53; protein, 3·02; fat, 2·13; fibre, 0·03; non-nitrogenous extract, including carbohydrates (galactan), 1·88; and ash, 0·41 per cent. This soy-milk can be easily converted into a durable product resembling condensed cow's milk, by adding cane sugar and a small quantity of dipotassium phosphate (to prevent separation of protein), and evaporating *in vacuo*. The condensed soy-milk has a considerable nutritive value, but cannot replace cows' milk or mothers' milk in the nourishment of infants. Adulteration of condensed cows' milk by condensed soy-milk could be detected by addition of sodium carbonate, when a yellow coloration would indicate the presence of the latter. Also, if a portion of the suspected milk were mixed with twice its bulk of water, treated with a few drops of dilute sulphuric acid, and one-tenth of the whole distilled off, the distillate would possess the characteristic odour of the raw beans, if soy-milk were present. Adulteration might also be detected by separating the casein from the suspected sample with rennet, and adding calcium nitrate to the filtrate; the formation of a precipitate would indicate the presence of the globulin of soy-milk, the so-called glycinin.—A. S.

Cheese; Preparation of a vegetable —— from the protein of the soy-bean. T. Katayama. Bull. Coll. Agric., Tokyo Imp. Univ., 1906, **7**, 117—119.

THE soy-bean when boiled with water yields a milk (see preceding abstract), of which the chief proteid constituent is glycinin, a globulin similar in properties to legumin, and having the following composition: Carbon, 52·12; hydrogen, 6·93; nitrogen, 17·53; sulphur, 0·79; and oxygen, 22·03 per cent. (See Osborne and Campbell, this J., 1898, 784). Soy-milk when treated with calcium and magnesium salts, yields a precipitate, which is sold in Japan under the name of Tofu. The author has attempted the preparation of a cheese from Tofu. 450 grms. of pressed Tofu were mixed with 60 grms. of common salt, 50 grms. of pressed milk casein, 2 grms. of milk sugar, and 2 grms. of finely-ground Swiss cheese, and the mixture was wrapped in a linen cloth saturated with brine, and left for five months in a room with an average temperature of 15° C. At the end of this time the mass was of a grey colour, and quite compact; it was free from the numerous pores produced by evolution of gas in Swiss cheese. The cheese had an agreeable taste different from that of Swiss cheese, and when extracted with water, yielded a solution in which the presence of albumoses and peptones was detected. Further experiments with mixtures containing larger quantities of milk-sugar, but no casein, gave similar results.—A. S.

Algæ; Fresh water —— as an article of human food. S. Namikawa. Bull. Coll. Agric., Tokyo Imp. Univ., 1906, **7**, 123—124.

Nostoc Phylloderma, of the group of the *Schizophyceæ* (Suizenji-nori, kotobuki-nori). The algæ are collected in small nets, and cleaned from other algæ; they are then cut into small pieces, spread on bricks, and dried in the sun into thin sheets. About 2 litres of fresh algæ yield one sheet of 2 square ft.; five sheets weigh 90 grms., and cost 2½ yen. The commercial product contains 18·07 per cent. of moisture, and the dry substance has the following composition: Crude protein, 24·75; crude fat, 0·93; crude fibre, 3·64; pentosans, 4·50; galactan 1·86; ash, 12·28; other matters (chiefly starch), 58·40 per cent. It contains lecithin, but no mannan, sugar, or tannin.

Another kind of fresh water algæ used as a foodstuff in Japan is *Prasiola japonica* of the group of the *Chlorophyceæ* (Daiyagawa-nori, Nikko-nori).—A. S.

Albuminoid and gelatinous substances; Determination of —— by means of acetone. F. Bordas and Touplain. XXIII., page 716.

FRENCH PATENTS.

Alimentary product [Albuminoid containing metal salts]; Preparation of an —— from yeast. G. Jacquemin. Fr. Pat. 361,356, April 12, 1905.

SEVERAL ways of obtaining the product are described, all of which are based on the fact that yeast is capable of absorbing and fixing metallic and other salts. The yeast, for instance, may be grown in a medium containing a soluble iron salt, or boiled with an iron solution. The cells of the yeast may be burst, and the mass then mixed with the metallic salt solution; the product is finally precipitated from the mixture by the addition of alcohol or sodium sulphate. In all the above cases the

product is dried, and powdered for use, or it may be dissolved in suitable solvents, and evaporated to form a scale preparation.—W. P. S.

Cereals and their husks; Process of bleaching and sterilising ——. O. Zimmermann and C. H. Buchenau. Fr. Pat. 361,363, Dec. 4, 1905.

See Eng. Pat. 25,010 of 1905; this J., 1906, 387.—T.F.B.

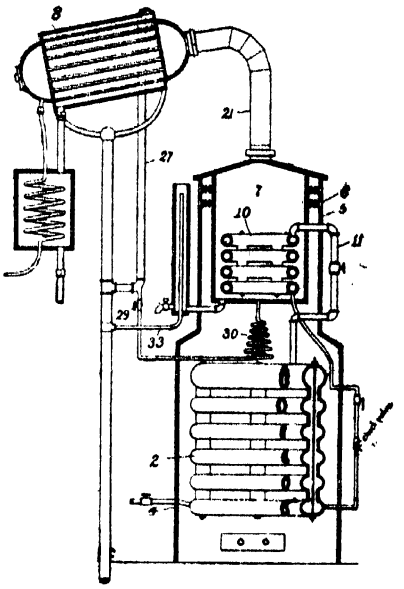
Milk, &c.; Alkali-butyrometric method for the determination of fat in ——. A. Sichler. Fr. Pat. 362,444, Jan. 10, 1906. XXIII., page 716.

(*B.*)—SANITATION; WATER PURIFICATION.

Water bacteria; Biology of the ——. E. Kohn. Cent. Bakt. (Abth. 2), 1906, **15**; Woch. f. Brau., 1906, **23**, 319.

When samples of good natural water are kept for a long time, the micro-organisms vary in quantity and relative proportions. The increase in the number of germs is greatest in vessels of those sorts of glass which are the most soluble in water. At high temperatures, the micro-organisms increase faster than at low temperatures, but their number again decreases faster than at low temperatures. The relative proportions of the different species vary according to the rule that the most exacting forms appear first, but are subsequently replaced by forms which have lower requirements. The former species grow in presence of 15 per cent. of dextrose, but the latter are already somewhat at a disadvantage with only 5 per cent. of dextrose; they prefer some simpler form of carbonaceous nutrient. The minimum proportions of dextrose necessary for the development of the more exacting species lie between the limits of 198×10^{-10} and 198×10^{-13} per cent. The minimum proportions of dextrose required by the species which appear later lie between 198×10^{-14} and 198×10^{-18} per cent. The minimum limits of nitrogenous nutrition are, in the case of ammonium sulphate and ammonium phosphate, between 66×10^{-18} and 66×10^{-19}. The minimum limits of phosphatic nutrition could not be determined, since water extracts, even from the most insoluble sorts of glass, more phosphates than the minimum required.—J. F. B.

English Patent.



Sewage and the like; Separation of solid matters from ——. C. Kremer and Ges. für Abwasserklarmy, m.b. H., Berlin. Eng. Pat. 5908, March 12, 1906.

The sewage is first freed from floating and heavy impurities by treating it in tanks similar to those described in Eng. Pat. 14,603 of 1901, and 14,461 of 1903 (this J., 1902, 917; 1903, 1095). The sludge settling at the bottom of the tank is moved, by means of a scraper extending across the bottom of the tank, to a channel communicating with a second tank. Instead of the channel, a screw conveyor, situated in a tubular channel at the front of the tank, may be employed. The scraper is curved upwards, so that when it is moved to its final position, the channel or the screw conveyor, is completely cut off from communication with the tank. The sludge ferments in the second tank, and is separated into a floating layer, which is removed and can be used as a manure, and a layer consisting chiefly of sand, which remains at the bottom of the tank. The fermentation of the sludge may be accelerated by the application of heat.—W. P. S.

United States Patent.

Water-still. R. P. Barnstead, Boston, Mass. U.S. Pat. 823,488, June 12, 1906.

A boiler, 2, is enclosed above a source of heat by a casing, 4, and communicates by the pipe, 11, with the coil, 10, in the evaporator, 7, which is placed above the boiler, 2, and is enclosed by the casing, 5, having openings, 6, in its upper part to allow the products of combustion to escape. The vapours from the evaporator, 7, pass by the pipe, 21, to the tubular condenser, 8, the water overflow of which, 27, is connected by the pipe, 33, provided

with a valve, 29, to the coil, 30. The latter is placed immediately above the boiler, 2, and communicates at its upper end with the under side of the evaporator, 7. —W. H. C.

French Patent.

Water and sewage; Process for purifying and sterilising Mme. Salarnier, *née* M. A. Lagogué, and la Soc. J. Jean et Cie. Fr. Pat. 361,332. April 6, 1905.

The water is led into a funnel, where it is mixed with kaolin, and then falls on to horizontal fans revolving at a high speed and placed in the upper part of a tall cylinder. The fine spray of water thus formed falls on to a circular plate inclining towards the centre of the cylinder, and passes down a central pipe to the bottom of the cylinder, whence it rises through the space between the pipe and the outer wall. This space is provided with a number of superposed baffle-plates on which the solid matters are collected, whilst the clear water leaves the cylinder by a pipe, and is conducted to a filter. Besides atomising the water, the fans draw a strong current of air into the cylinder for the purpose of aërating the water and oxidising the organic matter present. Means are provided for removing the sediment from the cylinder. Other substances, besides kaolin, may be added to the water; for instance, talc, infusorial earth, and phosphoric acid can be used. If phosphoric acid be employed, a corresponding amount of calcium carbonate must also be added.—W. P. S.

German Patent.

Sludge [from sewage purification]; Dehydration and utilisation [as manure] of ——. H. Grosse-Bohle. Ger. Pat. 167,700, May 26, 1904.

The sludge from sewage purification is difficult to utilise on account of its high content of moisture, the water-retaining properties being due to the fatty matters contained in the sludge. According to the present invention, the crude sludge, freed from coarser suspended particles, and, if necessary, diluted with water, is heated to a temperature above 50° C., whereby it separates into two layers; the upper layer, consisting mainly of froth, contains a large proportion of the fat originally present in the sludge. This layer of froth is removed, and is worked up for fatty acids and soaps, or is used for the manufacture of gas. The lower layer of sludge, poor in fat, can now be easily dehydrated by draining, filter-pressing, or centrifugalising, and yields a friable residue which can be used directly as a fertiliser.—A. S.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 654.)

Alkaloid salts of inactive secondary butyl-benzenesulphonic acid. A. Klages. Ber., 1906, **39**, 2131—2135.

ATTEMPTS were made to separate the alkaloid salts of racemic secondary butyl-benzenesulphonic acid into its active components by successive extractions with small quantities of solvent, but without success. If the anhydrous barium salt of secondary butyl-benzenesulphonic acid be warmed with phosphorus pentachloride, a colourless sulphochloride is produced, boiling at 179°—180° C. at 20 mm. The anilide melts at 63°—64° C., and the sulphamide at 80°—81° C. The alkaloid salts were produced by treating the barium salt of the sulphonic acid with the sulphate of the required base. Quinine secondary butyl-benzenesulphonate melts at 184° C., and has $[\alpha]_D^{20} = -10{\cdot}5°$. The cinchonine and morphine salts could not be properly crystallised. Cinchonidine secondary butyl-benzenesulphonate forms colourless glistening needles, melting at 205° C., and with $[\alpha]_D^{20} = -7{\cdot}34°$. The brucine salt was oily. Strychnine secondary butyl-benzenesulphonate crystallises in fine needles, melting at 189°—190° C., and is optically inactive.—F. SHDN.

Brazilian drugs; Notes on some ——. T. Peckolt. Ber. Deutsch. Pharm. Ges., **16**, 176. Pharm. J., 1906, **76**, 757.

Jatropha Curcas.—The seeds of the ripe kernel yield, by cold pressure, 22 per cent., and by hot pressure, 40 per cent. of a colourless, odourless fixed oil, with a taste resembling that of castor oil. By extraction with petroleum spirit, 44 per cent. of oil is obtained, but some resin is also extracted, and imparts an acrid taste to the oil. The seeds, freed from their cotyledons, or slightly roasted to remove the poisonous principle, curcin, are employed as a purgative. A 10 per cent. decoction of the leaves has hæmostatic properties.—A. S.

Lime juice; Ascertaining the strength of concentrated ——, *by means of a hydrometer.* F. Watts. West Indian Bull., 1906, **7**, 36—39.

THE strength of a concentrated lime juice can readily be ascertained by diluting the liquid ten times, reading the specific gravity with a hydrometer, and referring to a table. By this procedure, the citric acid contents of a variety of juices of different concentrations were found to agree within technical limits with the results of titrations. The author deprecates carrying the concentration further than 8 : 1, and recommends boiling down till the citrometer shows 60° in the boiling liquid, when the strength will be approximately 100 oz. of citric acid per gallon.
—W. A. C.

Terpenes and ethereal oils; Contributions to our knowledge of ——. 81*st Communication.* O. Wallach. Annalen, 1906, **347**, 316—346.

THE present communication deals with the simplest methene hydrocarbons, and their transformation into alicyclic aldehydes. The subject is treated under the following headings:—Pentacyclic compounds: methene cyclopentane. Hexacyclic compounds: derivatives of cyclohexanone; methenecyclohexane, hexahydrobenzaldehyde; derivatives of 1.2-(α-) methylcyclohexanone; derivatives of active 1.3-(β-) methylcyclohexanone, methene-1-methyl-3-cyclohexane; derivatives of 1.4-(γ-) methylcyclohexanone, methene-1-methyl-4-cyclohexane.

Pyrazolones; New methods of synthesis of ——. C. Moureu and I. Lazennec. Compt. rend., 1906, **142**, 1534—1537.

ETHYL amylpropiolate, $C_5H_{11}.C{:}C.COOC_2H_5$, and ethyl caprolylacetate, $C_3H_{11}.CO.CH_2.COOC_2H_5$, condense with phenylhydrazine to give the same amylphenylpyrazolone melting at 96° C. Similarly, ethyl hexylpropiolate, $C_6H_{13}C{:}C.COOC_2H_5$, and methyl heptylylacetate, $C_6H_{13}.CO.CH_2.COOC_2H_5$, give the same hexylphenylpyrazolone melting at 84°—85° C. Hydrazine will also react with acetylenic amides, ammonia being eliminated. Phenylpropiolamide, $C_6H_5.C{:}C.CONH_2$, when heated with hydrazine gives a phenylpyrazolone melting at 237° C. This product is identical with that obtained either from ethyl phenylpropiolate or ethyl benzoylacetate. Another method of making pyrazolones is by the interaction of hydrazines and alkylated β-hydroxyacrylic esters. Thus hydrazine hydrate and phenylethoxyacrylic ester, $C_6H_5.C(OC_2H_5){:}CH.COOC_2H_5$, give the phenylpyrazolone melting at 237° C. If phenylhydrazine be used in place of hydrazine in this latter reaction, diphenylpyrazolone is produced, melting at 256° C., and identical with that obtained by Knorr on heating cinnamyl phenylhydrazide. The author considers that where the acetylene linking is absent, the hydrazine replaces the alkyl grouping of the ester, and then the chain closes to form a pyrazolone. But where the acetylene linking is present, the acetylene linking itself is first attacked.
—F. SHDN.

Sulpho-acetic acid. O. Stillich. J. prakt. Chem., 1906, **73**, 538—544.

THE preparation of sulpho-acetic acid by heating together sulphuric and acetic acids was tried at different temperatures and with different proportions of the reacting substances. The yield varies with the temperature and with the amount of water in the sulphuric or acetic acids. Using 15 grms. of acetic acid and 25 grms. of sulphuric acid, both being free from water, 4 grms. of sulpho acetic acid were obtained by heating at 198° C. for 30 minutes. Sulpho-acetic acid may also be prepared from chlorosulphonic acid and glacial acetic acid, or from acetic anhydride and sulphuric acid, but the yields obtained are small.

The best method of preparation is from chloracetic acid, and sodium sulphite. Fifty grms. of chloracetic acid, 300 c.c. of water, 70 grms. of sodium carbonate, and 130 grms. of crystallised sodium sulphite are boiled together for 20 minutes, when no more sulphur dioxide should come off. 130 grms. of barium chloride in 200 c.c. of water are then added; any sulphate in the solution is precipitated; from the filtrate barium sulpho-acetate can be crystallised, the yield being 92 per cent. of the theoretical. The free acid is obtained from its barium salt by means of sulphuric acid. On evaporating the aqueous solution of the acid *in vacuo*, crystals are obtained; these are sulpho-acetic acid with one molecule of water (m. pt. 84°—86° C.). The acid is soluble in acetone and alcohol, insoluble in ether, nitrobenzene, and chloroform. It is not decomposed by boiling with water, acids, or alkalis.

—C. E. F.

s-Tetrachlorethane and hexachlorethane; Methods of preparation of ——. F. Michel. Z. angew. Chem., 1906, **19**, 1095—1097.

s-Tetrachlorethane.—Into a mixture of sulphur chloride with 1 per cent. of its weight of reduced iron, chlorine gas is led, the unabsorbed chlorine expelled by carbon dioxide, and dry acetylene led in, keeping the temperature below 40° C. When absorption slackens, excess of acetylene is expelled by carbon dioxide, and chlorine led in. The alternation of chlorine and acetylene is kept up till neither gas is absorbed to any extent, and the mixture is then shaken with water to decompose the remaining sulphur chloride, and steam-distilled. The distillate is washed with dilute sodium carbonate solution, separated from this, dried, and fractionated. It is chiefly *s*-tetrachlorethane, with a little of the penta- and hexachloro-compounds.

Hexachlorethane.—Through the same original mixture, boiling under a reflux condenser, acetylene is first led, then (after expulsion of excess) chlorine till yellow incondensable vapours appear, and the alternation continued as above, ending with excess of chlorine. The hot liquid is poured off, and allowed to cool, separated from the crystals of hexachlorethane (which are pressed between filter-paper), and treated again as above, after adding a little more reduced iron. This treatment is repeated as long as practicable, and the final mother liquor is concentrated by distillation, and leaves a further crop of crystals on cooling. The crystals are sublimed in steam, dried, and crystallised from alcohol.—J. T. D.

Formaldehyde; A comparison of some of the methods for determining ——. F. Russ and B. Larsen. Mitt. techn.-Gew. Museums, 1906, **16**, 85—98.

WITH solutions of pure formaldehyde Romijn's iodometric method (this J., 1897, 366), Legler's ammonia method (this J., 1897, 367), and Lemme's sulphite method (this J., 1903, 1107) all give trustworthy results, and the concentration of the solution has no influence on the figures obtained. It is quite otherwise, however, in the case of commercial formaldehyde. With solutions containing 0·8 per cent., or more, of the aldehyde, concordant results are obtained by all the methods, but the more the solution is diluted, the higher the apparent percentage of aldehyde becomes. For instance, a sample of commercial formaldehyde showing an average content of 40 per cent. when a 0·8 per cent. solution of it was employed for the determinations, gave 78 per cent. of aldehyde when a 0·1 per cent. solution of it was analysed. These anomalous results are due presumably to impurities in the commercial aldehyde. Of these impurities, methyl alcohol and acetone are the most common, and the authors record a number of experiments the results of which show that the presence of acetone leads to the formation of iodoform in the iodine method, whilst methyl alcohol acts as a non-electrolyte, and depresses the dissociation of the electrolytes in the reaction. This depression depends on the ratio of the non-electrolyte to the electrolyte. The reason for the inaccurate results obtained on decreasing the strength of the solution is not thus, however, fully explained, and at present remains an open question. The investigation simply shows that solutions containing not less than 0·5 per cent. of aldehyde must be used, to obtain trustworthy results.—W. P. S.

Iodomercurates of magnesium and manganese. A. Duboin. Comptes rend., 1906, **142**, 1338—1339.

BY the same process as in the case of calcium (this J., 1906, 283), the author has obtained the salts $MgI_2.2HgI_2.7H_2O$; $MgI_2.HgI_2.9H_2O$; and $3MgI_2.5HgI_2.20H_2O$. Their general behaviour is similar to that of the calcium iodomercurates.—J. T. D.

Mercurous and mercuric sulphates; Action of iodine on ——. K. Brückner. Monatsh. Chem., 1906, **27**, 541—349.

MERCUROUS oxide and iodine mixed in the proportions $6Hg_2O+12I_2$, interact, when gently warmed, forming a mixture of mercuric iodide and iodate, which can be separated by dissolving the iodide in alcohol. In presence of water the change only takes place slowly, but may be facilitated by boiling; in alcoholic solution interaction only takes place very slowly. The author assumes that the mercurous iodide is first converted into mercuric oxide and mercuric iodide. Mercuric oxide interacts with iodine in accordance with the equation

$$6HgO+12I=5HgI_2+HgI_2O_6,$$

both when carefully heated in the dry state, and also, more rapidly, in the presence of water. Alcohol causes a more gradual change, being itself oxidised to aldehyde by the iodate.

Mercurous sulphate and iodine, when powdered together and heated, react to form a yellowish-white, hard crystalline substance, which is decomposed by water into mercuric iodide and mercuric sulphate, and is probably the double salt, $HgI_2.HgSO_4$. In presence of water the reaction takes place very rapidly, mercury iodide and iodate being formed, and sulphuric acid going into solution. With alcohol the change is also rapid: the alcohol is oxidised in part to aldehyde by the iodate, whilst the sulphur trioxide collects in the alcohol.

Mercuric sulphate and iodine do not interact when heated together dry. If, after water has been added to the sulphate, converting it into yellow basic sulphate, iodine be introduced, the first result is the formation of mercuric iodide, which in course of time reacts with the residual sulphate, forming colourless compounds, probably double salts of mercuric iodide and sulphate. A similar compound is at once formed on moistening a finely-powdered mixture of sulphate and iodine. In presence of alcohol only iodide and iodate are formed, whilst the alcohol is oxidised to aldehyde.—E. F. A.

ENGLISH PATENTS.

Acetylene and chlorine gases; Manufacture of compounds of ——. J. H. Lidholm, Alby, Sweden. Eng. Pat. 22,094, Oct. 30, 1905. Under Int. Conv., April 28, 1905.

SEE Fr. Pat. 358,146 of 1905; this J., 1906, 197.—T. F. B.

Formates; Process for the manufacture of ——. Electrochemische Werke G.m.b.H., Bitterfeld, Germany. Eng. Pat. 772, Jan. 11, 1906. Under Int. Conv., April 14, 1905.

SEE Fr. Pat. 362,417 of 1906; following these.—T. F. B.

Isobornyl esters; Manufacture of ——. Chem. Fabr. von Heyden, Akt.-Ges., Radebeul, Germany. Eng. Pat. 10,999, May 10, 1906. Under Int. Conv., Sept. 4, 1905.

Isobornyl esters are prepared by heating pinene hydrochloride or hydrobromide with fatty acids and fatty acid salts of zinc, copper, or iron, or of other heavy metals, in presence of zinc halide. For example, isobornyl acetate is obtained by boiling under a reflux condenser a mixture of 172 parts of pinene hydrochloride and 500 parts of glacial acetic acid with 45 parts of zinc oxide, or with 165 parts of lead oxide and 30 parts of zinc chloride. —A. S.

Lithium salt [*Lithium thymate*]; *Manufacture of a new* ——. G. B. Ellis, London. From Firm E. Merck, Darmstadt, Germany. Eng. Pat. 21,280, Oct. 19, 1905.

Lithium thymate is prepared by adding lithia lye to an aqueous solution of thymic acid, until the liquid is slightly alkaline, and then precipitating the salt by means of alcohol. It may also be obtained by adding a solution of lithium sulphate to barium thymate solution, filtering off the barium sulphate, and precipitating the lithium thymate from the solution by alcohol.—A. S.

United States Patents.

Camphoryl-ethoxyphenylimide, and process of making same. A. H. C. Heitmann and E. C. Clemmensen, Assignors to Parke, Davis, and Co., Detroit, Mich. U.S. Pat. 824,357, June 26, 1906.

Camphoric acid and aminophenetol are condensed together, forming camphoryl-ethoxyphenylimide, a substance possessing antipyretic and analgesic properties; its m. pt. is 119°C., it is colourless, tasteless, insoluble in water, readily soluble in hot dilute alcohol and in "organic" solvents; it is insoluble in acid or alkali solutions. The general process of preparing camphoryl-alkyloxyphenylimides, by condensing two substances containing respectively the camphoryl group and the alkyloxyphenyl radical, one of which substances is also an amino-compound, is also claimed. The condensation is effected by heat and in presence of a solvent of high boiling point. —T. F. B.

Remedy; Process of making an internal —— [*from m-iodo-o hydroxyquinoline-sulphonic acid*]. R. Griese, Berlin. U.S. Pat. 824,539, June 26, 1906.

See Eng. Pat. 9656 of 1905; this J., 1905, 1188.—T. F. B.

French Patents.

Mono-iodo substitution products of higher fatty acids: Production of ——. Farbenfabrik. vorm. F. Bayer und Co. Fr. Pat. 362,370, Jan. 12, 1906. Under Int. Conv., May 5, 1905.

Higher fatty acids of the oleic series, such as erucic, oleic, elaidic, and brassidic acids, &c., are heated with hydriodic acid and glacial acetic acid at a low temperature under pressure. In order to make products which can be kept, the iodo acids are converted into their neutral earthy-alkaline or magnesium salts.—F. Shdn.

Formates; Production of ——. Elektrochem. Werke Ges.-m.b.H. Fr. Pat. 362,417, Jan. 15, 1906. Under Int. Conv., April 14, 1905.

In this process for the production of formates, caustic alkali is broken into large pieces, and carbon monoxide led over it at a temperature of about 100°—120° C., and under pressure. There is no necessity to reduce the alkali to fine powder, nor need it be subdivided by any inert medium as chalk or carbon.—F. Shdn.

1-Phenyl-2.3-dimethyl-4-amino-5-pyrazolone [*Amino-antipyrine*]; *Process for the alkylation of* ——. Soc. Chim. des Usines du Rhône ancien. Gilliard, P. Monnet, and Cartier. Fr. Pat. 362,465, Jan. 17, 1906. Under Int. Conv., Jan. 18, 1905.

A quantitative yield of a di-alkyl product can be obtained by the action of dimethyl sulphate on 1-phenyl-2.3-dimethyl-4-amino-5-pyrazolone (amino-antipyrine) at a temperature of about 100° C. with or without the use of indifferent solvents. The dimethyl sulphate can be replaced by ethyl sulphate or other homologues.—F. Shdn.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 655.)

Explosion of gunpowder; Circumstances attending an ——, *which occurred on the premises of Messrs. Truloch, Harriss, and Richardson, Ltd., of 9, Dawson Street, Dublin, on March 22, 1906.* By Major A. Cooper-Key, H.M. Inspector of Explosives.

A violent explosion took place whilst two workmen were engaged in breaking up a number of old 0·442 revolver cartridges in order to recover the lead of the bullets. The method employed consisted in holding the cartridges on the edge of a steel hammer, and tapping round the rim to knock out the bullet. A large quantity of loose explosive had already been removed, and was scattered about the bench, and a 25 lb. tin, two-thirds filled with old powder, stood on the floor. Whilst a cartridge was undergoing the tapping operation a flash occurred, followed by a loud explosion, which injured the men, and did considerable damage to the premises and to a public hall adjoining. It is pointed out that it is illegal to carry on the operation of breaking up loaded cartridges except in a licensed factory. The use of steel tools and the practice of carrying out such work in unsuitable premises is strongly condemned. An examination of the powder safe which was situated some distance from the scene of the explosion revealed the fact that 12 lb. of powder and a quantity of safety cartridges were stored together. Attention is drawn to the need for greater stringency in the administration of the Explosives Act by the local authorities.—B. J. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 656.)

APPARATUS, ETC.

Thermometer for low temperatures. A. Stock and C. Nielsen. Ber., 1906, **39**, 2066—2069.

From a bulb of 25 c.c. capacity there issues downwards a narrow tube 85 c.m. long, graduated in m.m. The lower end passes through and is rigidly fastened in the narrow opening of one limb of a wide U-tube, and dips 3 or 4 cm. below the mercury which half fills the U-tube. The graduations on the narrow tube are marked from 780 at the bottom up to 740. The limb of the U-tube containing the narrow tube is furnished with a second opening, which is plugged with cotton-wool; and the other limb is provided with a stopcock. This arrangement allows of the instrument being adjusted at any time, so that the level of the mercury in the inner limb shall stand at the graduation corresponding to the barometer for the time being. A thin-walled vertical glass tube, 3 mm. outside diameter and 65 c.m. long, sealed at its lower end, is connected to the top of the 25 c.c. bulb through a glass spiral or zig-zag, which allows some play. The apparatus is filled with pure dry oxygen by means of a side-tube in the bulb which can be connected with an air pump and a supply of the gas, and which is ultimately sealed off. When the long sealed tube is placed in a substance of

low temperature, the pressure is reduced to the vapour-pressure of oxygen at that temperature, and the mercury rises in the graduated tube. This tube can either be marked in millimetres, and the temperature read off from a table, or it can be directly marked with temperatures. The author has constructed a mean curve from the observations of Estreicher, Olszewski, Baly and Travers, and Senter and Jaquerod, from which the following table of temperatures and vapour pressures is taken :—

—200°	75 mm.	—194°	289 mm.	—188°	402 mm.
—199°	89	—193°	218	—187°	449
—198°	105	—192°	249	—186°	503
—197°	123	—191°	282	—185°	560
—196°	142	—190°	319	—184°	621
—195°	164	—189°	358	—183°	687

The principle of the apparatus can be applied to other gases or vapours besides oxygen.—J. T. D.

Ultramicroscope ; The ——, and its application in chemistry. L. Michaelis. Z. angew. Chem., 1906, **19**, 948—953.

THE construction of the ultramicroscope is based upon the principle that if a powerful beam of light be projected on an object at right angles to the axis of the microscope, instead of parallel to it, as in the ordinary instrument, particles much smaller than those which it is possible to see under the microscope, are rendered luminous, and appear as round spots of light to the observer. With the ordinary microscope, it is impossible to distinguish objects with a diameter less than 0·2 μ, but with the ultramicroscope the limit is 4 $\mu\mu$, and lenses of very great magnifying power are not required. It should be noted that the colour of particles observed in the ultramicroscope is frequently complementary to the ordinary colour by reflected light. The ultramicroscope has been used in the examination of solutions of albumin, glycogen, and dyestuffs, and also colloidal metal solutions. It has been found that dyestuffs may be divided into classes according to the optical behaviour of their solutions when examined by the ultramicroscope. Some dyestuff solutions behave exactly like colloidal gold solution (this J., 1902, 1250), the particles of dyestuffs showing up in their complementary colour on a dark ground. To this class belong "soluble Prussian Blue" and some organic colouring matters of high molecular weight, as Violet Black, Indulin, and Nigrosin. Fluorescent dyestuffs, on the other hand, give solutions in which no distinct particles can be perceived, although when a beam of light is projected through such a solution, its path appears luminous. It appears evident that the particles in a fluorescent solution are of a much smaller size than those in a colloidal metal solution. Many dyestuffs belong to neither of the groups mentioned, but occupy an intermediate position ; luminous particles can be observed in their solutions by the ultramicroscope, but not in sufficient quantity to represent the whole of the dyestuffs present, the remainder being in the form of a true solution. In the case of Thionine (Lauth's Violet), the salts of the dyestuff dissolve to a true solution, whereas the solution of the colour base itself in water is a suspension of ultramicroscopic particles ; a toluene solution of the colour base exhibits fluorescence when examined by the ultramicroscope, but no luminous particles can be observed.—A. S.

ENGLISH PATENT.

Gas ; Automatic apparatus for analysing ——. E. Schatz, Frankfort on Maine, Germany. Eng. Pat. 1841, Jan. 24, 1906. Under Int. Conv., April 12, 1905.

SEE Addition of Nov. 28, 1905, to Fr. Pat. 359,352 of 1905 ; this J., 1906, 529.—T. F. B.

INORGANIC—QUALITATIVE.

Arsenic, antimony, and tin ; Detection and separation of ——. O. Materne. Bull. Soc. Chim. Belg., 1906, **20**, 46—68.

THE method recommended for the separation of arsenic, antimony, and tin, when stannous sulphide is present (A), differs somewhat from that to be used in the presence of stannic sulphide (B).

A. *The mixed sulphides are boiled with a 2 per cent. solution of borax, containing ammonium chloride.*

Residue. Boiled with a 5 per cent. solution of sodium carbonate, containing ammonium chloride.		*Filtrate.* Arsenic sulphide precipitated by hydrochloric acid.
Residue is stannous sulphide.	*Filtrate.* Antimony sulphide is precipitated by hydrochloric acid.	

B. *The mixed sulphides are digested with a cold 2 per cent. solution of borax, containing ammonium chloride, for 10 minutes.*

Residue. Dissolved in a 5 per cent. solution of caustic soda. Heated with tartaric acid and ammonium chloride.		*Filtrate.* Arsenic sulphide precipitated by hydrochloric acid.
Precipitate is antimony sulphide.	*Filtrate.* Stannic sulphide precipitated by hydrochloric acid.	

Another very rapid method is the following :—

The mixed sulphides are boiled with sodium carbonate solution.

	Filtrate. Cooled.	
Residue is stannous sulphide.	*Precipitate* is Antimony sulphide.	*Filtrate.* Arsenic sulphide precipitated by hydrochloric acid.

The methods may be applied quantitatively for the separation of arsenic from antimony and tin, but not for separating these from each other. The three sulphides are completely removed from those of the cadmium group by a 10 per cent. solution of caustic soda, if allowed to stand for half-an-hour after being heated to boiling.

It has been incidentally established that stannous sulphide is oxidised to a mixture of stannic sulphide and stannic chloride, when boiled with dilute hydrochloric acid in the presence of air ; and also that antimony sulphide is dissolved by alkali chromates or bichromates, chromium hydroxide being precipitated.—F. SODN.

INORGANIC—QUANTITATIVE.

Gas analysis ; Sodium hyposulphite (hydrosulphite) in ——. H. Franzen. Ber., 1906, **39**, 2069—2071.

THE author uses sodium hyposulphite as an absorbent for oxygen. In Hempel's apparatus, the pipette is filled with rolls of iron wire gauze, and the solution used is made by dissolving 50 grms. of the salt in 250 c.c. of water, and adding 40 c.c. of sodium hydroxide solution (500 grms. of hydroxide dissolved in 700 c.c. of water). Of this solution, 1 c.c. will absorb about 10 c.c. of oxygen, and five minutes standing in the pipette is enough. In Bunte's burette, a solution of 10 grms. of hyposulphite in 50 c.c. of water, to which has been added 50 c.c. of 10 per cent. sodium hydroxide solution is used.

This reagent is cheaper and much more comfortably handled than pyrogallol, can be used in presence of carbon monoxide, and absorbs as readily at low as at high temperatures. Comparison with analyses by other methods has proved its accuracy.—J. T. D.

Ozone ; Use of —— in quantitative analysis. P. Jannasch and W. Gottschalk. J. prakt. Chem., 1906, **73**, 497—519.

A CONVENIENT apparatus for the preparation of ozone is described. The discharge from a small induction coil is passed between the walls of five or six Berthelot tubes arranged in series. The tubes are filled with water containing a little sulphuric acid, and stand in a cylindrical glass vessel filled with the same liquid. The inner coat-

ings of each tube are all joined to the same pole, and the outer coatings to the other pole. A current of air or oxygen after first passing through a tube containing sulphuric acid and another containing soda-lime, is passed through the ozonising apparatus. The current is controlled by a stopcock, and no rubber connections are possible. By passing oxygen through an apparatus containing six tubes, the resulting gas was found to contain 8 per cent. of ozone. Ozone is an excellent precipitant for manganese. An ammoniacal solution containing 0·0001 grm. of manganous sulphate gives with ozone, a precipitate of hydrated peroxide of manganese. The deposition is complete, and the precipitate is bulkier and lighter in colour than when hydrogen peroxide is used as the precipitant, and it is easy to filter. To determine manganese in a manganous salt, the salt is dissolved in a small quantity of warm water, or hydrochloric acid if necessary, and is placed in a dropping funnel. Every 12 seconds one drop of the solution is allowed to fall into 100 c.c. of a solution of ammonia saturated with ozone, and through which ozone is being passed. After all the liquid has run out, the funnel is rinsed with water, and the current of ozone continued for about 15 minutes. The precipitate is filtered, and ignited to protosesquioxide, Mn_3O_4. The results obtained by the author with this method are very good.

By this method, the separation of manganese from sodium, calcium, zinc, and nickel is complete. In solutions containing copper, cadmium, or magnesium, the manganese precipitate is impure owing to absorption of the other salts. In these cases, the precipitate is dissolved in hydrochloric acid, and again dropped into an ammoniacal solution containing ozone. Methods for the separation of manganese from other metals are being investigated.—C. E. F.

ORGANIC—QUALITATIVE.

Milk; A condensed vegetable ——. T. Katayama. XVIIIA., page 710.

ORGANIC—QUANTITATIVE.

Beeswax; Examination of ——. P. Bohrisch and R. Richter. XII., page 701.

Sucrose and raffinose; Optical determination of mixtures of ——. J. Pieraerts. Bull. Assoc. Chim. Sucr. et Dist., 1906, **23**, 1261—1265.

Under suitable conditions, raffinose is completely converted into melibiose and lævulose by citric acid. Upon this reaction the author has based a method for the polarimetric determination of mixtures of sucrose and raffinose. To determine the degree of resistance of levulose during hydrolysis with citric acid, solutions of known strength containing pure sucrose and raffinose were analysed. 10 grms. of the substance were dissolved in 50 c.c. of warm distilled water, poured into a 100 c.c. cylinder, cooled, made up to volume, mixed, and filtered. 25 c.c. of the filtrate were transferred to a 50 c.c. flask, 2 c.c. of alumina cream added, the solution made up to volume, mixed, filtered, and polarised in a 200 mm.-tube. 50 c.c. of the original solution were hydrolysed by boiling for 15 minutes with 10 c.c. of 20 per cent. citric acid solution in a 250 c.c. flask fitted with a reflux condenser. The solution was then rapidly cooled, transferred to a 100 c.c. cylinder, and 2 c.c. of alumina cream added. The solution was then made up to volume, mixed, filtered, and the filtrate polarised in a 200-mm. tube. For degrees of angular rotation, the following equations give the percentages of sucrose and raffinose in the sample:—

$$a = 40\frac{66{\cdot}5}{100}x + 40\frac{104{\cdot}5}{100}y\,;\quad a' = -40\frac{19{\cdot}84}{95}x + 40\frac{53}{100}y$$

a = direct polarimeter reading; a^1 = reading after hydrolysis.

x = amount of sucrose contained in 100 c.c. of the 5 per cent. solution.

y = amount of hydrated raffinose contained in 100 c.c. of the 5 per cent. solution.

From the above equations the following values are obtained for x and y:—

$$x = 9{\cdot}287003a - 18{\cdot}31116a^1$$
$$y = 3{\cdot}6594667a + 11{\cdot}65256092a^1$$

The results, which are tabulated, show that the levulose remains quite unaltered during the above process of hydrolysis, and that the method may be used for rapid and accurate estimations of mixtures of sucrose and raffinose. The equations are valid only for a temperature of 20° C. The author gives tables of corrections for temperatures from 15° to 25° C.—L. E.

Amylocelluloses [Insoluble amyloses] in natural starches; Determination of the ——. J. Wolff. Ann. Rev. Chem. anal., 1906; Woch. f. Brau., 1906, **23**, 316.

The principle described in a previous paper (this J., 1906, 139) for the determination of starch coagulated by malt extract, may be applied to the determination of the various grades of amylocelluloses (insoluble starch) present in the natural starches. The method is based on the observation of Roux, that even the most resistant amylocelluloses are soluble in water at 145° C., and that the solution, if rapidly cooled to 65° C., and treated immediately with malt extract, can be completely saccharified before any reversion has taken place. (*a*) 2·5 grms. of starch are mixed with 50 c.c. of water, and heated for 30 minutes at 145°—150° C.; the solution is cooled rapidly to 65° C., and 10 c.c. of a 10 per cent. malt extract are added at once. When the liquid is saccharified, it is diluted to 200 c.c., and filtered; 100 c.c. of the filtrate are then converted into dextrose by adding 1 c.c. of sulphuric acid, and heating in the autoclave at 120° C. for 20 minutes. The dextrose solution is diluted to 200 c.c., and the reducing sugar is determined. (*b*) 2·5 grms. of starch and 50 c.c. of water are heated at 100° C., and subsequently treated in exactly the same manner as (*a*). (*c*) 2·5 grms. of starch and 50 c.c. of water are gelatinised by raising the temperature to 100° C.; the paste is allowed to remain for four hours at the ordinary temperature, and is then saccharified by malt extract at 65° C., the subsequent conversion into dextrose being effected in the same manner as that of *a* and *b*. The difference *a*—*c* then gives the dextrose equivalent of the amylocelluloses which are insoluble at 65° C. The difference *a*—*b* gives the dextrose equivalent of the amylocelluloses which are insoluble at 100° C., whilst the difference (*a*—*c*)—(*a*—*b*) gives those which are soluble only between 65° and 100° C. The value *a*, corrected for the dextrose equivalent of the malt extract, gives the dextrose equivalent of the total starch substance, soluble and insoluble amyloses.—J. F. B.

Albuminoid and gelatinous substances; Determination of —— by means of acetone. F. Bordas and Touplain. Comptes rend., 1906, **142**, 1345—1346.

Acetone, whether pure or diluted with water, precipitates completely albuminoids, gelatinous substances, diastases, and peptones. This, coupled with the fact that pure acetone dissolves fats and resins, while aqueous acetone dissolves many salts, affords a basis for the separation of these classes of bodies, in, for example, foods, gelatinous or caseous distempers, "polygraph" gelatins, &c. The following are details in the case of certain foods:—*Butter:* 10 grms. are exhausted, first with pure acetone, then with aqueous acetone; the weight of the dried residue less the ash gives the casein. *Cheese:* About 2 grms. are emulsified in 5—10 c.c. of water, and 35 c.c. of acetone are added gradually and with continuous agitation. The insoluble portion is thoroughly washed with aqueous and finally with pure acetone, and then the residue consists of casein and ash. *Milk:* 10 c.c. are poured into 20 c.c. of acetone, shaken, the precipitate separated centrifugally from the liquid, and washed with aqueous and then with pure acetone. The proteids so separated dry very readily, and are weighed and incinerated, deducting the ash as usual.—J. T. D.

French Patent.

Milk, &c.; Alkali-butyrometric method for the determination of fat in ——. A. Sichler. Fr. Pat. 362,444, Jan. 10, 1906. Under Int. Conv., Jan. 10, 1905.

Ten c.c. of the milk, 10 c.c. of a solution containing

sodium phosphate or sodium carbonate, and 1 c.c. of butyl or isobutyl alcohol are placed in a butyrometer tube, and well mixed. After standing, the fat separates completely, and its volume may be read off. A colouring matter, preferably an alizarin derivative, may be added to the butyl alcohol to facilitate the reading of the volume of the fat.—W. P. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 611.)

Metallic "ferments." P. Sabatier. Bull. Soc. Chim. Belg., 1906, **20**. 13—15.

THE author defines a ferment as any substance which, by virtue of forming unstable compounds, can bring about some transformation in an unlimited quantity of material. He views both oxidations and hydrogenations attained through the agency of finely-divided metals as fermentations, and for the following reasons:—

1. The activity of the metallic ferments depends on the conditions of preparation. 2. Their action is seriously affected by the presence of traces of other bodies. 3. Their activity exhibits three stages: development, normal exercise, and decline.—F. SODN.

Catalysis [*Platinum-black*] *and enzyme action; Similarity between* ——. E. H. Neilson. Amer. J. Physiol., 1905, **15**. 148—152; Woch. f. Brau., 1906, **23**. 303.

THE author treated the glucosides, salicin and amygdalin, with platinum-black at a temperature of 40°—42° C., and observed a hydrolytic splitting similar to that which takes place under the action of the enzyme emulsin. The hydrolysis of the salicin could be conducted under conditions exactly comparable with those of enzyme hydrolysis, but that of the amygdalin could only be effected in open flasks, since the hydrocyanic acid produced in the reaction and a strong inhibitive influence on the catalysis; benzaldehyde was also produced.—J. F. B.

Metallic oxides; Employment of —— as oxidising catalysts. P. Sabatier and A. Mailhe. Comptes rend., 1906, **142**, 1394—1395.

IN consequence of a note on this subject by Matignon and Trannoy (Comptes. rend., **142**, 1210), the authors make a preliminary statement as to the behaviour of cupric oxide, a train of which, in a glass tube, with a stream of oxygen containing the vapour of a paraffin hydrocarbon directed upon it, becomes incandescent at the point of impingement when heated in the first place to 200° C., and remains incandescent in the stream without further external heating. The oxides of nickel and cobalt behave similarly. The paraffins from methane to heptane behave thus, and are oxidised completely, save a trace which is converted into aldehyde or fatty acid.—J. T. D.

Wood; Action of bacteria on ——. B. Malenkovic. Z. landw. Vers. Oesterr., 1905, **8**; Woch. f. Brau., 1906, **23**. 300.

A CONCENTRATED aqueous decoction of wood-sawdust has an acid reaction, and, when solidified by agar, it forms a medium on which moulds will develop, but which will not support the growth of bacteria. The resins of the coniferous woods and the tannins of the dicotyledonous woods possess an antiseptic influence against bacteria. If, however, the wood-extract be neutralised, preferably by chalk, the solution forms a fairly good nutrient medium for a vast number of aërobic and anaerobic species of bacteria. This extract does not, however, afford support for the development of the bacteria which bring about the fermentation of cellulose. Whilst these bacteria, which occur in the soil, readily ferment cotton, filter-paper, and similar forms of cellulose, they have practically no action on wood-cellulose [sulphite pulp]. The lignocellulose of wood, after purification by solvents, is also perfectly resistant to the attack of bacteria, but mould fungi grow on it readily. Sawdust treated with dilute solutions of potassium phosphate and ammonium nitrate, was found to be considerably decayed after a year, but bacteria were present only in traces. A round-shaped budding fungus, apparently a torula yeast, is always present in decaying wood, and appears to play an important part in the decomposition. If wood be placed in a solution containing 0·1 per cent. of potassium phosphate and 0·25 per cent. of ammonium nitrate, a vigorous fermentation, accompanied by frothing and evolution of gas, sets in after a few days, but this fermentation does not take place if the wood has previously been purified by extraction. The denitrifying bacteria attack only the extractive matters of the wood.—J. F. B.

Cholesterol; Constitution of ——. A. Windaus. Ber., 1906, **39**, 2008—2014.

CHOLESTEROL can be converted by way of a nitro derivative into a saturated ketonic alcohol, cholestanonol, $C_{27}H_{44}O_2$ (this J., 1903, 1261), and into a diketone, cholestandione (Ber., 1903, 3752), in which the two ketonic groups must stand in a 1:4, 1:5, 1:6, or 1:7 position towards each other (Ber., 1904, 4753). Wallach concluded that cholestanonol differed from cholesterol only in the group $CH:C<$ of the latter being converted into CO.CH; whilst Diels and Abderhalden (Ber., 1906, 884) considered that the reactions observed in the reduction of cholesterol and the corresponding ketone, cholestenone, agreed best with the α,β-position of the double bond. To test this assumption, the author oxidised cholestenone with a neutral solution of potassium permanganate, 20 grms. of the ketone in 200 c.c. of benzene being shaken for six hours with the reagent. The manganese peroxide was then destroyed by means of sulphurous acid, and the organic matter taken up with ether, and separated into acid and neutral products by means of dilute potassium hydroxide solution. The main product was a ketomonocarboxylic acid, $C_{26}H_{42}O_3$, which on further oxidation yielded a tricarboxylic acid, $C_{26}H_{42}O_6$, and there was also a small quantity of a mono-carboxylic acid, $C_{27}H_{44}O_4$, which the author regarded as an intermediate product. This crystallised in long thin needles melting at 217°—218° C. The acid, $C_{26}H_{42}O_3$, crystallised mainly in white plates melting at 155° C. It formed an oxime crystallising in long thin prisms melting at 191° C., and a bromine derivative, $C_{26}H_{41}O_3Br$., in microscopic needles melting at 154°—156° C. The tricarboxylic acid, $C_{26}H_{42}O_6$, formed by the oxidation of the acid, $C_{26}H_{42}O_3$, by means of bromine, crystallised from benzene in star-shaped clusters of microscopic needles (m. pt., 120°—131°). It was very hygroscopic. The author's general conclusion from these experiments is that the simplest explanation for the conversion of cholestenone into the ketomonocarboxylic acid is to assume the presence of a group, $CH.CH_2$, which is decomposed on oxidation thus:—

$$C_{25}H_{41}O.CH.CH_2 + 5O = C_{25}H_{41}O.COOH + H_2O + CO_2.$$

He considers that the conception of cholestenone as an α,β-unsaturated ketone cannot be accepted. (See also this J., 1904, 1117.)—C. A. M.

Lactic acid; Resolution of —— by morphine. J. C. Irvine. Chem. Soc. Proc., 1906, **22**, 159.

FERMENTATION lactic acid may be readily resolved into its active components by the crystallisation of the morphine salts. On neutralising an aqueous solution of the inactive acid with the alkaloid, the sparingly soluble morphine *l*-lactate separated almost quantitatively, whilst the compound with the *d*-acid remained in solution. The crystalline morphine salt was converted into zinc *l*-lactate, which gave $[\alpha]_D^{20^\circ} = +6{\cdot}84^\circ$, and a more accurate test of the purity of the active acid was obtained by its conversion by means of the silver oxide reaction into methylic *l*-methoxypropionate, which showed $[\alpha]_D^{20^\circ} = +94{\cdot}7^\circ$

The latter compound was reduced by hydriodic acid to *l*-lactic acid, a reaction which shows that silver oxide does not affect the configuration of an active lactate.

By decomposing the syrup containing the soluble morphine *d*-lactate, more than 50 per cent. of the theoretical yield of the active zinc salt ($[\alpha]_D^{20} = -6{\cdot}83^\circ$) was obtained.

Trade Report.

GERMANY; TRADE OF —— IN 1905.
For. Off. Ann. Ser. No. 3657.

The following table shows the value of the general imports and exports for the year 1905, as compared with those of the years 1903—04. The figures for 1905 are calculated according to the prices fixed for 1904:—

Value in 1000 marks (50*l.*).

New Books.

INDUSTRIAL FURNACES AND METHODS OF CONTROL. By EMILIO DAMOUR. Translated and augmented by A. L. Queneau. The Engineering and Mining Journal, New York and London. 505, Pearl Street, New York; 20, Bucklersbury, London, E.C. 1906. Price 4 dols., post paid.

CROWN 8vo volume, containing 299 pages of subject matter, with 88 engravings and illustrations, six pages of bibliography, and the alphabetical index. There are also 24 tables. The contents are subdivided as follows:—PART I. (i) Heat of Combustion and Calorific Power, &c.; (ii) Gas Furnaces; (iii) Heat Utilisation in Furnaces, Efficiency, &c.; (iv) Direct-fired Furnaces; (v—vii) Gas-fired Furnaces; (viii) Classification of Furnaces; (ix) Experimental Study of Heat Utilisation in Furnaces; (x) Theory of Heat Recuperation, &c. PART II. (xi) Pyrometric Practice and Instruments, &c.; (xii) Gas Analysis; (xiii) Calorimetry; (xiv) Elementary Fuel Analysis, &c. PART III. (xv) Chimneys—Construction, Height, &c.; (xvi) Regenerators; (xvii) Recuperators; (xviii) Reversing Valves, Hearth, Ports; (xix) Powdered Fuel; (xx) United States Patents covering the Stoking of Powdered Fuel.

DANGEROUS TRADES.—ACTION TAKEN BY THE HOME OFFICE. [Cd. 3037.]

THE Home Office has issued in the form of a circular, particulars as to the action taken respecting various dangerous trades under the Factory and Workshops Acts, 1891, 1895, and 1901. The circular is to be obtained from any bookseller, price 1d.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1905. [Cd. 3036.] Wyman and Sons, Fetter Lane, E.C. Price, 3s. 6d.

THE report contains a general review of the work of the Factory Department in 1905; sectional reports (including appendices on paints and colours, tar distilling, air samples, and other subjects); statutory orders; appeals; memoranda (including Aniline Black dyeing, industrial mercurial poisoning, notification of industrial poisoning xylonite and celluloid); and statistical tables.

RESEARCHES ON CELLULOSE. II. (1900—1905). By C. F. CROSS and E. J. BEVAN. Longmans, Green, and Co., London, New York, and Bombay. 1906. Price, 7s. 6d.

CROWN 8vo volume, containing 174 pages of subject-matter, 6 pages of bibliographical notes, and indexes of authors and of subjects. The purpose of the volume is to record the recent progress in our knowledge of cellulose, and chiefly to answer the question, "What is cellulose?" The work is sub-divided as follows:—Section I. General résumé and forecast. (1.) Cellulose as a typical colloid. (2.) Cellulose as a chemical individual. (3.) Cellulose and structural forms—Dimensions. Section II. Account of original investigations in the period 1900—1905; abstracts of authors' communications, followed by critical examination of matter and results from the point of view of theoretical forecast of Section I. A. Reactions of synthesis: Nitric esters; aceto-sulphates, cellulose-xanthogenic acid; cellulose and alkaline hydrates; theory of dyeing; electrolytic phenomena; constitution of cellulose. B. Reactions of resolution and decomposition; hydrocellulose; mixed esters—chloracetyl derivatives of hydrocelluloses, &c.; animal digestion, and assimilation of cellulose; destructive fermentation. General summary and conclusions as to experimental verifications of views expounded in Section I. Section III. Technical progress in cellulose industries, and general forecast of technological developments from the point of view of matter in Section I.

Official Notice.

ALCOHOL FOR INDUSTRIAL PURPOSES.

The Revenue Bill, which includes facilities for the use, without payment of duty, of spirits in arts and manufactures (this J., 1905, 397—426; *ib.* 706) has received the Royal assent. After having been considered in Committee, the report stage passed the House of Commons without discussion on July 27, and the Bill was read a first time in the House of Lords on the same date. The second reading was carried without dissent on July 31, and the third reading took place on the same afternoon. Rules and regulations for the use of duty-free spirit will be issued on October 1st next.

Birmingham and Nottingham Sections.

Meeting held at Burton on Tuesday, April 26th, 1906.

MR. J. M. C. PATON IN THE CHAIR.

THE BEHAVIOUR OF COLLOIDS IN SEWAGE.

BY F. R. O'SHAUGHNESSY, A.R.C.SC., F.I.C., AND H. W. KINNERSLEY, F.I.C.

The object of this communication is to bring forward a number of results of observations and experiments made by one of us at different times over several years, together with the results of a more special investigation undertaken jointly by us during the past few months.

Messrs. W. Biltz and O. Köhnke,* and Messrs. Jones and Travis,† of Hampton-on-Thames, have made statements with respect to colloidal matter in domestic sewages, and Dr. Fowler and Mr. Ardern,‡ of Manchester, have investigated the effects of the presence of manufacturing refuse on these liquids.

It occurred to us that useful information might be obtained by experimenting separately with the two principal ingredients of sewage, *viz.*, urine and solid fæcal matter. The apparatus used in these and the other experiments where the method of dialysis was adopted, was similar to that described by Dr. Fowler in his excellent paper above referred to.

Method of experiment.—A parchment cylinder 8 cm. in diameter (supported on a rigid framework) and a glass cylinder of exactly double the sectional area of the first cylinder were used.

Five hundred c.c. of the liquor under investigation were placed in the glass vessel, and an equal bulk of distilled water was introduced into the parchment cylinder. The smaller vessel was then placed in the larger, and as the parchment is slightly collapsable the two liquids readily adjusted themselves to the same level. It was ascertained that diffusion was not always complete in 24 hours (theoretically it requires an infinite time), so the operation was allowed to proceed for a minimum time of two days.

By this means one may separate a known portion (one-half) of the crystalloids present in the original liquor and so compute the ratio of crystalloids to colloids.

Dr. Fowler is not very clear as to the meaning of the ratio he gives. When dialysis is complete the following formula will give the true ratio of crystalloids to colloids:—

Let x represent, say, the "oxygen absorbed" figure outside parchment.

Let y represent, say, the "oxygen absorbed" figure inside parchment.

Then $\frac{x-y}{2.y.}$ gives the ratio of oxidisable crystalloids to oxidisable colloids in the original liquid.

In our tables we have preferred to express the percentage of colloids on the total matter present.

We may illustrate the method by taking a table from Dr. Fowler's paper as follows:—

"*Comparison of settled septic tank effluent with settled sewage.*"

Results in grains per gallon.

Samples taken after diffusion was complete.	3 mins. oxygen test.		Album. ammonia.	
	Settled sewage.	Settled septic liquor.	Settled sewage.	Settled septic liquor.
I.				
From inside parchment cylinder.....	0·80	0·66	0·06	0·04
From outside parchment cylinder.....	1·20	1·28	0·19	0·165
Fowler's ratio ..	1—1·5	1—1·9	1—3·2	1—4
Ratio of crystalloids to colloids	4—1	2·1—1	1—1·1	1—1·6
Ditto as per cent. of colloids ...	25%	47·6%	52%	61%

This does not alter Dr. Fowler's conclusion, however, but it shows—what would naturally be expected in a sewage like that of Manchester—that the oxidisable crystalloids are greatly in excess of the oxidisable colloids; and, moreover, this method of expressing by percentages brings the main fact out at once quite clearly.

In our tables we give comparative figures for four hours, and three minutes, oxygen tests, together with a number of "Albuminoid Ammonia" figures and "Dissolved Solids." Besides this we give a figure which we call the "Permanent Colloids Ratio," which is obtained as follows:—

$$100 \times \frac{\text{(4 hrs. ox.) (outside)} - \text{(3 mins. ox.) (outside)} - \text{(4 hrs. ox.) (inside)} - \text{(3 mins. ox.) (inside)}}{\text{(4 hrs. ox.) (outside)} - \text{(3 mins. ox.) (outside)} + \text{(4 hrs. ox.) (inside)} - \text{(3 mins. ox.) (inside)}}$$

Experiments with fæcal solids.—(*a*) About 150 grms. of fæces was shaken up in a stoppered cylinder with 1000 c.c. of water and allowed to subside for 24 hours, when the supernatant liquor (which was quite opaque owing to colloidal matter) was syphoned off and dialysed in the above apparatus. The results are given under (*a*) Table I.

(*b*) The same liquor was diluted (1 : 19) and dialysed.

(*c*) It was also incubated for 10 days and dialysed after incubation. The results are given under (*b*) and (*c*) in Table I.

(*d*) About 1 lb. of fresh fæcal matter was incubated at 80° F. with 6 qts. of tap water in a vessel open to the air for seven days; 500 c.c. of the liquor were drawn off, settled, diluted with an equal bulk of tap water, and dialysed. The results are given under (*d*) in Table I.

(*e*) The incubation in the foregoing experiment was continued for 13 days and the liquor treated as before. The results are given under (*e*) in Table I.

(*f*) Experiment (*d*) was conducted in the absence of air. The results are given under (*f*) in Table I.

The effect of adding lime and chloride of iron separately and together to a solution of fæcal matter was tried with the following results:—

	3 mins. oxygen absorbed
Untreated liquor	5·20 parts per 100,000.
After adding lime and settling 24 hours	2·51 „ „ „
After adding ferric chloride and settling 24 hours	4·00 „ „ „
After adding both together and settling 24 hours	1·50 „ „ „

* "Organic Colloids from Town Sewage," Berichte der deutschen chemischen Gesellschaft, Vol. xxxvii., p. 1745.

† "Elimination of Suspended Solids and Colloidal Matters from Sewage." Proceedings of the Institution of Civil Engineers, 1905–06.

‡ "Suspended Matters in Sewage and Effluents." This J., 1905, 483.

Experiments with urine.—(*a*) The urine was settled and the clear liquid syphoned off and diluted (1:9). It was then dialysed with an equal bulk of tap water. The results are given under (*a*) in Table II.

(*b*) Another sample of mixed urine from eight persons was settled and diluted (1:19). The diluted liquid was then dialysed with an equal bulk of tap water. The results are given under (*b*) in Table II.

(*c*) A sample of urine which had been standing in stoppered bottle for six years was diluted (1:19) and dialysed with an equal bulk of tap water.

Note.—A thick sediment had settled at the bottom of the bottle containing the urine. The results are given under (*c*) in Table II.

(*d*) *Examination of pan liquor.*—The liquor from a pan which was used occasionally for the reception of defæcations was drawn off and settled. The pan was emptied five weeks previously. The liquor consisted, of course, of urine and such matter as was taken up from the solids present. It was diluted (1:9) and dialysed with an equal bulk of tap water. The results are given under (*d*) in Table II.

Birmingham sewage.—In Table III. *A.* is given the results of examination of samples of Birmingham settled crude sewage by dialysis.

In Table III. *B.* is given the results of a similar examination of Birmingham sewage discharged during a holiday, when most of the works were stopped. The flow was reduced about 30 per cent.

Birmingham tank liquors.—All the sewages on Table III. mix together and pass through the roughing tanks, where partial sedimentation (four hours) and septic action takes place. The liquor then passes on to the septic tanks, where it sojourns for an average period of 8½ hours.

The results are given in Table IV.

The septic liquor passes on to the main conduit, which is five miles long, and from which the liquor is drawn off at various points on to the land.

Domestic sewages.—At a point some two miles from the septic tanks 2,500,000 galls. of the liquor—in Table V. designated "sedimentation tank effluent"—enter the conduit. This Cole Valley sewage is typical of a fairly fresh domestic sewage, as is also the Hanley sewage given in the same table.

Septic liquor for bacteria beds.—The Birmingham septic liquor arriving at the end of the five-mile conduit passes first through a series of silt tanks, where the suspended solids are reduced to about 8 parts per 100,000.

The results of the examination of this important liquid after issuing from the silt tanks are given in Table IV.

Solids arrested in silt tanks.—The silt tank is of the shape of an inverted cone, and the finely divided matter in the septic liquor entering the tanks sinks slowly to the bottom during the four hours required for the passage of the liquid through the tank.

The solid matter is discharged in small quantities three times daily from a valve situate at the apex of the inverted cone. It was found that it was necessary to empty the tanks three times per day in order to prevent them from acting as septic tanks. The number of organisms present in the liquor entering and leaving the tanks was estimated under varying conditions in order to settle this point. This sludge is quite black in colour, has very little smell, "works" vigorously, and contains some 45 per cent. of organic matter.

Solids precipitated in bacteria beds.—Both the solids accumulating in the top of the bacteria beds, and those passing out in suspension in the bacteria beds' effluent, must consist very largely of colloidal matter precipitated from the liquor passing on to the bed in addition to the usually small quantity of sediment also present in the liquor.

Solids from the top 12 in. of a Percolation Bed.

General characteristics.—The sludge adheres to the particles of medium, filling up the interstices as a black slimy mass. It appears to be pulverulent (in finely divided grains), but is so finely divided for the most part that it has a soapy feel in the fingers. It has, when fresh, the faint, not unpleasant odour of well-digested septic sludge.

Microscopical characteristics.—Under a magnification of 100 diameters, the sludge appears to consist almost entirely of dark structureless matter, along with some small portions of organic matter in the last stages of disintegration (cellulose of cell-walls ?). Many fine quartz grains appear intermixed with the dark matter.

Under magnification of 650 diameters the same characteristics were observed. Some particles of organic matter showed fragmentary cell structure (cellulose); very few organisms of the larger forms could be seen (two spindle-shaped forms as well as several other forms were observed), but the mass is crowded with non-motile coccus forms, whilst a much smaller number of bacteria were observed.

Chemical characteristics.—The sample under examination was found to contain 42 per cent. of organic matter. On extraction with ether the dry matter yielded 2·95 per cent. of ether extract having a gummy consistence and very pungent smell.

Solids passing out of the Bacteria Bed in Suspension in the Effluent.

General description.—The sludge, arrested by the "separator tank" from the effluent, is of very fine texture, and has the appearance of impalpable slime. It is of a very dark brown colour when fresh, and has an earthy smell. In wet bulk after a time it sets up putrefactive decomposition with objectionable smell.

Microscopical characteristics.—Under a magnification of 100 diameters it appears to consist almost entirely of structureless "blobs" of dark matter interspersed with dead bodies of some of the higher water organisms, and many zooglea.

Under a magnification of 650 diameters the dead organisms appear to be undergoing disintegration, their cell walls being ruptured. The structureless matter above showed no structure under the higher power, and many zooglea were observed. The organisms were mostly coccus forms, and were present in huge numbers, whilst some bacteria and rod-like forms appeared. Also a number of what appeared to be rudimentary filaments were present.

Chemical characteristics.—The dry matter was found to contain 38·31 per cent. of organic matter in the sample under examination.

Another sample gave 40·6 per cent. of organic matter, 19 per cent. of silica, and much iron.

The chemical characteristics of these substances will be examined more fully later.

Mechanical examination.—The rate of fall of this sludge in water was determined with the following results:—

Heaviest (small) portion fell at rate of 170 ft. per hour.

Medium portion (the bulk of sludge) fell 21 ft. per hour.

Lightest particles fell at an average rate of 5·7 ft. per hour.

Subsequently the effluent was passed through the "separator tank" (an inverted cone) at varying rates, and the limiting speed of upward flow consistent with good sedimentation was found to be about 21 ft. per hour.

It may be remarked here that a number of experiments were made on a fairly large scale, both by sedimentation and filtration, to ascertain the most efficient method of arresting the suspended solids from the bacteria bed effluent. The Birmingham separator tank has been adopted as a result of these experiments.

Colloidal matter in land effluents.—The colloidal matter usually present in land effluents is very small in quantity and contains much mineral matter. The portion which separates on standing consists largely of hydrated oxide of iron and some silica, but the maximum amount so separating has not been found to exceed (even in an extreme case) 3 parts per 100,000. The average iron in solution in Birmingham land effluents when freshly sampled is 0·9 part per 100,000.

The effluent from Field 29 (east) is particularly interesting (see Table VI.). This effluent persistently gives a copious ferruginous deposit.

In 1901 an experiment was tried with this field, at the suggestion of one of us, with a view to preventing the iron in the sub-soil from going into solution in the effluent. The surface of the field was dressed with waste gas lime at the rate of 50 tons per acre, with the intention of increasing the basicity of the soil. The more soluble constituents of the gas lime quickly disappeared, but although the quantity of lime in the effluent was very large, the copious deposition of hydrated oxide of iron from the effluent was arrested only for a short time; some analyses of the dissolved matter present in this effluent are given below:—

Results in parts per 100,000.

Dissolved matter.	3 days after liming field.	6 days after liming field.	8 months after liming field.
$Fe_2O_3 + Al_2O_3$.	39·2	31·6	Fe = 2·2
CaO	40·0	6·4	41·0 ($CaCO_3$)
MgO	6·3	5·5	aftr. 9 dys. Fe = 0·27
Total solid matter	220·0	—	108·5

After four and a half years from time of liming the solids separating from the original clear liquid on standing 30 days = Total, 2·8 parts per 100,000; volatile, 0·5 part.

Colloids in biological bed effluents.—These effluents are usually similar in this respect to land effluents. (See Table VI.)

In Table VII. is given a series of analyses of a most interesting sewage containing enormous quantities of manufacturing waste.

The examination of such a liquid by dialysis furnishes extremely useful information.

Conclusions.

1. The amount of colloidal matter in solution in sewage varies greatly. The chief sources from which organic colloidal matter is derived are urine and fæcal matter. Urine is known to contain very little relatively to its other constituents, and our experiments demonstrate that the principal source of soluble colloids in sewage is fæcal matter. It is also shown that the fæcal matter passes into pseudo solution or emulsion by agitation with water, and that the amount usually taken up depends on (*a*) the nature of the other constituents of the liquor; (*b*) the time of contact and amount of agitation between the water and the fæcal solids.

The amount taken up under any circumstances is, of course, limited. Old or badly laid sewers will influence this result, and an interesting point is raised here with respect to the methods adopted in sampling and examining crude sewage.

2. Speaking generally, domestic sewage—unless very fresh—will contain more colloidal matter than a sewage containing much trades' waste. In the Hockley sewage (Birmingham) much pickling liquor is usually present with very little colloidal matter; as much as 12 parts of iron per 100,000 have been observed in this sewage.

We have experienced the greatest difficulty in inducing septic action in a sewage containing much iron salts. Apart from any sterilising action, this effect seems to be due more to the small amount of colloidal organic matter which such a sewage is capable of taking up in solution.

3. It is now generally admitted that the efficiency of the septic tank as a means of destroying sludge was at first greatly overrated.

The highest published figures are to the effect that some 25 per cent. of the sludge disappears in the resolving chamber; but our own observations make the figure 10 per cent. in our case. The exact figure is probably the result of local and more or less accidental conditions.

Also, care should be taken to discriminate between solid matter *eliminated as gas*, and solid matter which merely passes into emulsion on account of the agitation taking place as a result of the escape of this gas.

4. Resolution *per se*, *i.e.*, decomposition of the original solid sludge in a septic tank, must take place for the most part *after* the organic matter has passed into solution; for the organisms can only act on this matter through their enzymes. The amount of matter capable of passing into solution appears to be limited, so that the amount capable of bacterial disintegration in a reasonable time must be still more limited. The efficiency of anaërobic chambers where a large surface is presented to the dissolved colloidal matter can, therefore, be more readily understood.

5. Our experiments support the view that the amount of dissolved colloidal matter is increased by septic action. (See figures in Table IV.)*

6. It appears to us, therefore, that where a rapid means of getting rid of sludge *without nuisance* is at hand, septic treatment is a mistake; for the colloidal matter taken up in the septic tank is re-precipitated in the subsequent treatment of the liquor, and is then usually very troublesome to deal with.

7. In our own case the chief reason for continuing the septic treatment is because by this means the immense bulk of sludge to be dealt with on the land can be deprived of its objectionable smell. This deodorising effect on the large scale operations was observed by Mr. J. D. Watson, Engineer to the Birmingham Drainage Board, several years ago.

8. Septic liquor from which all visible suspended solids have been removed by sedimentation still contains much potential sludge, as Dr. Fowler has shown in the case of Manchester sewage.

The following table gives the amounts of matter separating from various samples of Birmingham sewages and septic liquors (clarified by settling) on being allowed to stand exposed to air.

Parts per 100,000.

Sample.	Total deposited matter.	Organic matter.		Days standing.
		Total.	Per cent. of dry matter.	
Hockley sewage (receives much iron pickle)	7·5	4·3	57·5	12
Cole Valley (Birmingham) sedimentation tank effluent (domestic)	6·7	4·8	71·6	7
Birmingham (silt tank) septic liquor (mixed sewages) ..	6·7	4·4	65·6	12
Ditto. ditto.	16·0	—	—	—
Ditto. ditto.	12·2	7·3	59·9	24
Ditto. ditto.	14·0	8·3	59·3	28

A sample of the strong solution of fæcal matter (see (*a*) Table I.) was diluted (1:9) and allowed to stand for six weeks. The liquor deposited 9·1 parts per 100,000 of solid matter which contained 86·4 per cent. of organic matter. The supernatant liquor was no longer opaque, but was still opalescent, and had lost its disagreeable odour.

9. The matter which separates on allowing a clear sample of septic liquor to stand is insoluble, has only a faint odour, is extremely stable, and even when incubated with water under most favourable circumstances decomposes with extreme slowness. These properties sharply distinguish this matter from the original sewage sludge.

10. One of the chief functions of any process of purification of the clarified sewage liquor is the removal of the potential sludge which it still contains. Where the liquor is treated on good land, only a trace of this matter is left in the effluent, and the same applies to effluents from efficient bacteria beds.

But whereas the land retains the whole of the solids in a condition requiring little further manipulation, this

* *Note.*—Owing to the easy liability of the "Albuminoid Ammonia" figure to error in these comparisons, this estimation is not regarded by us as being so reliable for this purpose.

matter passes out in part in suspension in the bacteria bed effluent, but a large part remains in the bacteria bed. From time to time this matter must either be flushed out of the bed, or the medium must be dug out and washed. At Birmingham the open tile floors of the percolation beds permit of each bed being easily flushed, whereby the solids accumulating are washed out of the bed.

Such flushings are passed through the same tank as the ordinary effluent from the bacteria bed. This tank, known as the "Birmingham Separator Tank," consists of a chamber of the shape of an inverted pyramid with a sump and exit pipe at the apex. The sludge accumulating is discharged on to the land. By this means the suspended solids are reduced to a little over 1 part per 100,000, and this method in common with land treatment ensures that the *whole* of the sludge is arrested from the various effluents.

Note.—The conflicting statements which are frequently made with respect to the rate at which bacteria beds tend to choke, are probably due to the varying proportions of colloidal solids (*i.e.*, potential sludge) present in different sewage liquors. How much of the sludge arrested *in* the bed is destroyed by bacterial action remains to be determined.

11. Our observations on the rate of disappearance of sludge are to the effect that even under very favourable circumstances it disappears for the most part with extreme slowness. Unless it is broken up and spread out in very thin layers it may remain apparently unaltered for years. Wherever it is kept in bulk it will remain for indefinite periods.

12. Iron appears to play a peculiar and most important part in the phenomena discussed above.

Iron (Fe) in solution in Birmingham crude sewage	0·24	parts	per	100,000.
Iron (Fe) in solution in Birmingham septic tank effluent	0·46	„	„	„
Iron (Fe) in solution in Birmingham land effluent	0·96	„	„	„

The form in which the iron is present seems to determine whether it assists or retards the operations. This matter, however, requires further investigation.

In conclusion, we wish to express our thanks to Mr. J. D. Watson for his permission to use these results, and for much valuable information supplied.

Discussion.

Mr. C. G. Matthews understood that the liquor remained eight and a half hours in the septic tank; was that a matter of convenience, or was it the time that gave the best results?

Mr. O'Shaughnessy said it was a matter of convenience.

Mr. Matthews, continuing, asked whether, in the case of an effluent from bacteriological beds which required a further sedimentation, it would not be possible to make the bacteriological beds in such a way that filtration would be efficient enough to provide an effluent that did not require another sedimentation and separation.

Mr. J. T. Wood asked if the percentage of colloids was really per 100 grms. of sewage?

Mr. O'Shaughnessy: No. The percentage was on 100 grms. of the dissolved matter in the sewage.

Mr. Wood said the whole question of colloids was a very important one. The general impression was that there was no sharp difference between colloids and crystalloids except one of degree. Had Mr. O'Shaughnessy read a very important paper by Zsigmondy, who proposed a classifying test for colloids which depended on the action of the colloids on a solution of metallic gold (this J., 1902, 192)? Zsigmondy was still working on the subject.

Mr. O'Shaughnessy said that he had not tested it in that way.

Mr. S. F. Burford said that although the septic tank had not fulfilled the expectations held out—that it was a universal solvent—it certainly was a most useful preliminary treatment in that it produced a uniform liquor from a sewage varying in flow and character.

Mr. J. Golding asked whether the iron could in any way be dealt with. In Lincolnshire the drains were often blocked up with it. He was very much interested to hear about the application of gas lime.

Mr. J. O'Sullivan said that the authors had referred to the size of the material used in the septic tank. Was it coke?

Mr. O'Shaughnessy replied that it was so in some of the filter beds.

Mr. O'Sullivan, continuing, said that the amount of septic change must depend upon the surface area of the medium.

The Chairman (Mr. J. M. C. Paton) asked what amount of sediment, say per million gallons, was left finally to be dealt with? When bacteria beds first became the fashion, it was said there would be absolutely no sludge left to be dealt with, but now in many places the sludge question had become a very important one.

Mr. F. E. Lott asked if in cases of excessive amount of iron in the soil the colloidal matter in the effluent was mainly organic, and whether it was usually precipitated before it was discharged from the land drains. In connection with the silt tank, the sludge had been referred to as "working vigorously and without smell." Did that vigorous working continue on exposure, and was there still no smell, or did further oxidation produce a more objectionable smell?

Mr. O'Shaughnessy, in reply to Mr. C. G. Matthews, said that in the course of time even the best bacteria beds tended to become choked and useless, and had to be stopped and cleaned out, unless provision were made for self-cleansing. He was grateful to Mr. Wood for his reference to Zsigmondy's work; he would take advantage of it. While admitting that the septic tank provided a means of mixing the sewage and rendering the flow uniform, the amount of sludge which it was said the septic tank would destroy was at first altogether overstated. In reply to Mr. F. E. Lott, who asked if, in the case of excessive iron in some sub-soils, the colloid matter in the effluent was chiefly organic, it was almost completely retained in the soil, and the colloid matter which passed out from such a sub-soil contained but a trace of organic matter. In the case given, the organic matter was only 0·05 parts per 100,000. Mr. Golding had asked if this precipitate in the land effluent could be kept from choking drains. The colloid matter itself would not choke the drains, but there was choking from another cause. An effluent furnished an excellent pabulum for the growth of certain organisms, iron bacteria chiefly, which had not, to his knowledge, been elaborately investigated, but the cost of removing them was considerable. They could not be eliminated, and the only means of preventing the land drains from being completely choked on account of the growth of these organisms was to flush them out two or three times a week. Provision was made for flushing them by putting stops in the manhole, and allowing the excessive quantity of water, which in this case accumulated rapidly to head up. The suspended matter is afterwards screened out of the effluent. With regard to the size of the medium in the beds, the cost of experimenting on a large scale was so prohibitive that it had not been done exhaustively. It was not safe to dogmatise as to the best size of the medium, in the absence of more substantial evidence than was available at present. The amount of solid coming out of any particular bacteria bed varied greatly. It might be only a mere trace. The effluent, especially when beginning to use a bed, might be as clear as tap water. That was because the suspended matter, the colloidal matter chiefly, was being held up in the bed. A rough sort of equilibrium was established after some time. The suspended matter increased until it reached in some cases from 16 to 20 parts per 100,000. After that had passed through this separator tank, the suspended matter was less than two parts per 100,000.

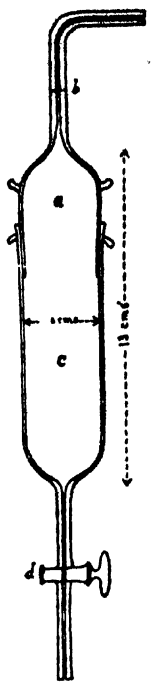
MR. EUSTACE CAREY IN THE CHAIR.

THE VOLUME-EXPANSION OF PORTLAND CEMENT.

BY F. G. DONNAN AND J. T. BARKER.



(*From the Muspratt Laboratory of Physical and Electro-Chemistry, University of Liverpool.*)

Introduction.—The examination of Portland cement for volume-stability or soundness involves two points, (*a*), the method of measuring the expansion, (*b*), the conditions to which the cement is subjected. With regard to the first point, most specifications for cement have, until quite recently, only required the crude "pat" test, which consists in observing the behaviour of a thin-edged pat of cement when exposed to a damp atmosphere at ordinary temperatures for varying periods of time (usually a week to 28 days). This still forms the German "normal" test.(1) More or less accurate methods of measuring the linear expansion of cylindrical blocks or slabs of cement have, however, been in existence for a long time. Writing in 1893, Le Chatelier(2) stated that Durand-Claye and Debray had for a long time employed a lever arrangement for measuring the expansion of long rods of cement. In the same place Le Chatelier describes his own arrangement of split-cylinder and lever-fork. This apparatus does not, however, measure linear expansions directly. For this purpose Bauschinger(3) has devised a somewhat elaborate apparatus, consisting essentially of a multiplying lever with compensating screw and divided circle. Quite recently, Martens(4) has described a much simpler apparatus in which the principle of multiplying lever is also employed. The Engineering Standards Committee(5) adopted in

1904 a slightly modified form of Le Chatelier's apparatus for employment in the British Standard Specification for Portland cement. They have also adopted Le Chatelier's method of allowing the cement to set for 24 hours in cold water, and then heating it in boiling water for six hours. This brings one to the second of the two points referred to at the beginning, namely, the method of treating the cement for the expansion test. With regard to this point, there has been, and doubtless still is, considerable diversity of opinion. Le Chatelier's method of heating the cement in boiling water for six hours was based on the results of a long experimental research on the nature and behaviour of hydraulic cements.(6) Like other chemical reactions, the hydration of lime and magnesia is greatly accelerated by rise of temperature. Any free lime or magnesia occurring in a badly manufactured cement only hydrates slowly at ordinary temperatures, owing to the high temperature to which it has been heated in the cement kilns. If this hydration occurs in the set cement or concrete, it will cause expansion (and sometimes even disintegration) of the solid mass, this expansion being due, not so much to any intrinsic increase of volume, as to the expansive force of crystallisation. The object, therefore, of the six hours' boiling is to ascertain the possible maximum of expansion due to these causes. The results obtained by Le Chatelier have been confirmed by the exhaustive experiments made by Tetmajer,(7) which indicate that the "accelerated" test (i.e., in boiling water) is necessary. It must be stated, however, that the Committee appointed by the Union of German Portland Cement Manufacturers arrived at a different conclusion.(8) According to their report, the ordinary pat test is sufficient. Besides the method of heating in boiling water (method of Le Chatelier and Michaëlis), there exist other accelerated tests which need not be enumerated here.(9)

The present investigation arose out of some experiments made to test the volume-stability of the Portland cement used in building the Muspratt Laboratory of Physical Chemistry of the University of Liverpool. For this purpose, the Le Chatelier apparatus was at first employed, but it seemed desirable to devise some more accurate and at the same time simple method of measuring the expansion produced. The idea naturally occurred that the most advantageous method would consist in measuring the total volume-expansion by some simple form of dilatometer. Having devised a suitable apparatus, some 20 different samples of English and Continental Portland cement were obtained from the manufacturers or their agents. These samples were all described as being fit and ready for use, and were not subjected to any preliminary process of aeration. The chief object in making these experiments was to ascertain the maximum volume-expansion exhibited by a large number of ordinarily used cements when exposed to boiling water, in the hope of obtaining thereby a standard test-value, which would apply to the majority of well manufactured cements. In certain cases, comparison tests were made with the Le Chatelier apparatus, in order to calibrate the latter by obtaining reduction-factors wherewith to convert its readings to true linear or volume-expansions. In all cases, duplicate bars of cement were allowed to remain in water at ordinary room temperature for considerable periods of time, in order to compare the hot and cold water tests.

Apparatus and method of measurement.—The volume-dilatometer employed is shown in Fig. 1. It is made entirely of glass, and consists of an upper portion, (*a*), to which is sealed the capillary tube, (*b*). By means of a well-ground joint, the upper part can be securely attached to the lower portion, (*c*), which consists of a cylindrical glass vessel, to the lower end of which is sealed the tube and small glass tap, (*d*). By employing a good vacuum-grease, such as the well-known mixture of vaseline, paraffin wax, and rubber, the joint between the upper and lower portions can be made perfectly air-tight. Owing to the porosity of the cement, it is necessary to use mercury as the dilatometric fluid. It might be possible to employ other liquids, such as dry mineral or vegetable oils, but no experiments have been made in that direction owing to the undoubted advantages possessed by mercury.

The apparatus is used as a weight-dilatometer. The capillary tube, (*b*), is attached by thick-walled pressure-tubing to a water-pump and the apparatus exhausted. The tap, (*d*), is then opened, and mercury allowed to fill the apparatus to a mark made on the vertical stem of the upper capillary tube. In order to avoid the changes of volume of the glass vessel due to considerable differences of pressure, the mercury is first allowed to rise to a point somewhat above the fixed mark, the tap, (*d*), is then closed, and air admitted to the upper capillary. It is then easy to run out mercury until it falls to the mark. The mercury in the stem of the lower tube below the tap having been removed,(10) the apparatus is disconnected from the pump, and the mercury filling it from the tap, (*d*), to the mark is run out into a porcelain dish and weighed. In this way the inner volume of the apparatus, expressed as a weight of mercury (about 1000 grms.), is obtained. The two halves of the apparatus are now disconnected, and the cylindrical test-bar of cement inserted into the lower half. The cylinder of cement was prepared by working the cement on a glazed fireclay slab with just enough water to form a plastic mass. The mixture was worked with a trowel for several minutes, and then introduced into a thin glass test-tube of the proper size (about 1 in. diameter), care being taken to remove air-bubbles and to obtain a compact mass. Although the different masses were not tested specially for equal plasticity, it was found that the amount of water could be gauged so accurately, that in different experiments with the same cement the amounts of water used did not differ by more than 1 per cent. The cement having been allowed to set hard for 24 hours, the thin glass walls of the tube were chipped off and the cement cylinder cut to the size required. The volume of the bar was then ascertained by inserting in the apparatus as described, connecting with the pump, exhausting, and then admitting mercury slowly through the tap, (*d*). During this process bubbles of air appear at the surface of the bar. These must be removed as much as possible by tapping. It was found best to admit the mercury until it had about half filled the upper portion of the apparatus, to then close the tap, (*d*), and exhaust again.

fairly completely. On now admitting air from the top any remaining air is driven into the pores of the cement. Sufficient suction is then finally applied to bring the mercury to the mark on the capillary, as described previously. The mercury in the apparatus from the tap, (*d*), to the mark on the capillary tube is then run out and weighed. The difference between this and the previous weight gives the volume of the bar expressed as a mass of mercury (usually about 300 grms.). Duplicate measurements of volume made in this way agreed within less than 0·1 per cent. The bars whose initial volumes had been ascertained were then heated in boiling water for successive periods of three to four hours, the volume of each bar being measured in the dilatometer after each period of heating. This was continued until no further increase of volume occurred. The period of heating required for complete expansion varied with different cements from 3 to 16 hours. The bars dry very quickly and can be inserted into the dilatometer as soon as they are cold. The diameter of the test pieces was such that they fitted easily into the lower portion of the dilatometer, but could not be pushed up by the mercury into the upper part.

3. *Experimental results.*—The following table gives the results of the expansion-measurements made in boiling water. In some cases comparison-tests were made with the Le Chatelier apparatus. The results of these are given in column (3). Column (2) gives the percentage of water by weight used in making the test cylinders. Column (4) gives the volume-expansion measured by the dilatometer expressed as a percentage. Column (5) the linear expansions obtained therefrom by dividing by three. In column (6) is given the number of hours' boiling required to produce maximum volume-expansion —*i.e.*, the expansion as given in column (4). In most cases duplicate determinations of volume-expansion were made. These determinations together with the mean values are given in column (4):—

TABLE I.—*Expansion of Portland Cement.*

(*Boiling Water.*)

Refce. No. of cement.	Water.	Expansion in Le Chatelier apparatus.	Volume expansion.	Linear expansion.	No. of hours boiling.
	per cent.	mm.	per cent.	per cent.	
1	26·0	14·5	5·64 5·93 } 5·78	1·92	7½

10	26·3	—	0·44	0·15	17½
11	25·0	(4·6)	0·34	0·11	19
12	26·0	5·5	0·43 0·34 } 0·38	0·13	7½
13	24·0	4·6	0·26 0·43 } 0·34	0·11	4
14	26·4	(4·6)	0·30 0·38 } 0·34	0·11	8
15	24·0	3·0	0·22 0·23 } 0·225	0·075	12
15	28·3	(2·6)	0·18 0·19 } 0·18	0·06	8
17	27·7	(2·2)	0·14	0·05	3
17	24·7	(1·74)	0·17 0·07 } 0·12	0·04	3
18	29·3	2·0	0·026 0·076 } 0·05	0·02	14
19	24·0	3·5	0·28 0·16 } 0·22	0·07	18

The numbers in brackets in column (3) were not obtained by direct measurement in the Le Chatelier apparatus, but were calculated as explained later on. The foregoing table exhibits the following noteworthy points:—

(*a*) Out of about 20 different cements tested, only five gave a volume-expansion of over 1 per cent.

(*b*) In four cases varying amounts of water were used in making the test-bars. In one case, (No. 4), the expansion was increased four and a half-fold by an increase in the water of 4 per cent. In another case, (No. 5), the expansion was diminished by one-half by an increase in the water of 3 per cent.

(*c*) In the case of No. 3, an interval of four days, during which the cement was standing in a paper bag exposed to the air of the laboratory, reduced the volume-expansion from 7·34 per cent. to 3·96 per cent. This result shows the great effect of even a comparatively short exposure to a damp atmosphere.

In most cases a third test-piece was made from the same mixture of cement and water, and after 24 hours' setting was immersed in water at ordinary room temperature for a considerable period of time, after which the increase in volume was determined by the dilatometer. The results are given in Table II.:—

TABLE II.—*Expansion of Portland Cement.*

(*Cold Water.*)

Refce. No. of cement.	Water.	Volume expansion.	Linear expansion.	Days in water.
	Per cent.	Per cent.	Per cent.	
A*	28·0	0·66	0·22	28

13	23·3	0·04	0·01	19
14	26·4	0·37	0·12	34
15	24·0	0·47	0·16	26
15	28·3	0·46	0·15	26
17	27·7	0·17	0·06	31
17	24·7	0·34	0·11	31
18	29·3	0·19	0·06	23

*In the boiling-water test this sample of cement completely disintegrated.

In connection with Table II. the following points may be noticed:—

(*a*) The first four samples of cement, which showed very large expansions when exposed to boiling water, only exhibited small expansions in cold water during the period of testing.

(*b*) The expansions in all cases are comparatively small.

(*c*) There does not seem to be any definite relationship between the two series of expansions. It may be noted, however, that with the exception of those cements which showed large expansions by the boiling water test, the expansions obtained in both cases are of the same order of magnitude.

In Table I. are given several measurements made on the same samples of gauged cement both with the Le Chatelier apparatus and the dilatometer. The following table shows the results of these comparisons:—

TABLE III.—*Comparison of Le Chatelier Apparatus and Dilatometer.*

Refce. No. of cement.	Linear expansions from dilatometer. (A)	Displacement of ends of arms of Le Chatelier's apparatus. (B)	A / B
	Per cent.	mm.	
15	0·075	3·0	0·025
19	0·073	3·5	0·021
13	0·113	4·6	0·025
12	0·127	5·4	0·023
3	1·32	16·4	0·081
1	1·927	14·5	0·133
2	4·83	35·6	0·136

It will be seen from this table that for small expansions the displacement of the arms of the Le Chatelier fork is proportional to the linear expansion, and that the percentage linear expansion can be calculated from the reading of the Le Chatelier apparatus by multiplying by 0·023. This proportionality ceases to hold when the expansions become greater, but it would seem that for expansions greater than about 2 per cent. linear, the readings of the Le Chatelier apparatus again become proportional to the linear expansion, the necessary multiplying factor now being about 0·134. The experiments recorded in Table III. are not sufficiently numerous, however, to enable one to construct a complete calibration-curve for the Le Chatelier apparatus.

4. *Conclusions.*—Judging from the results recorded in Table I., it may be said that a well-manufactured cement should not exhibit a greater maximum volume-expansion than 1 per cent. when exposed to the boiling water test. This applies to the cement as delivered for use, and to test-bars made as described in this paper. The allowance of 1 per cent. would seem to be amply sufficient, since the majority of the cements examined showed a smaller, and in many cases a very much smaller, expansion.

The allowance of 12 mm. displacement (in the Le Chatelier apparatus) permitted by the British Standard Specification for cement aerated for 24 hours, corresponds pretty closely to an expansion of 1 per cent. by volume. The allowance of 6 mm. (after seven days' aeration) corresponds to 0·144 per cent. volume-expansion.

These relationships may prove of use to those who wish to employ the dilatometer described in this paper in conjunction with the limits imposed by the British Standard Specification. In that case, of course, the bars need not be boiled for a longer period than the six hours mentioned in the Specification. The dilatometer described in this paper may be obtained from Messrs. Orme and Co., of Manchester and Liverpool (212, Mount Pleasant).

In conclusion, we have much pleasure in thanking Mr. W. Riding, Clerk of Works to Messrs. Willink and Thicknesse, for much assistance in the correct gauging of the cements.

MR. A. GORDON SALAMON IN THE CHAIR.

THE DETERMINATION OF INDIGOTIN IN COMMERCIAL INDIGO AND IN INDIGO-YIELDING PLANTS.

BY CYRIL BERGTHEIL AND RICHARD VICTOR BRIGGS.

The determination of indigotin in commercial indigo is a matter of great importance to the dyeing trade, and many methods have been described for its accomplishment. An excellent summary and bibliography of the subject may be found in a paper by J. Grossmann (this J., 1905, **24**, 308). Recent criticism by Bloxam (Trans. Chem. Soc., 1905, **87**, 974) has thrown doubt on all the methods hitherto proposed, and it has become necessary, for the purpose of the research work now in progress in India on the cultivation and manufacture of indigo, to re-examine the whole question.

As summarised by Grossmann (*loc. cit.*) the analytical methods hitherto proposed all fall under one of the following heads:—

I. The extraction of indigotin by solvents, and weighing the extracted material after more or less purification.

II. Sulphonation of the indigo, and volumetric determination of the indigotin by an oxidising agent.

III. Sulphonation of the indigo, and volumetric determination of the indigotin by a reducing agent.

IV. Reduction of the indigo, and separation of the indigotin by re-oxidation.

V. Sublimation of the indigotin.

To these should be added a method proposed by Möhlau and Zimmermann (Zeits. Farb. Text. Chem., 1903, **10**, 189) in which the indigo is acted upon by a mixture of acetic and sulphuric acids, whereby the indigotin is converted into a sulphate which remains dissolved in the acetic acid, and is subsequently hydrolysed by pouring the solution into water, and the precipitated indigotin weighed as such.

Our experience has led us to agree with the opinions expressed by Grossmann on the methods coming under headings I., IV., and V. In our attempts to obtain the impurities occurring in natural indigo free from indigotin, we had occasion to test the extractive action of all the solvents hitherto proposed, and in no case were we able to entirely remove the indigotin from the material, or to obtain the indigotin from the solvent direct in a pure condition. Analytical methods founded on this principle are, therefore, valueless. The same applies to methods coming under headings IV. and V.; in neither case can the indigotin be obtained direct in a pure form. We have, therefore, confined our attention to methods depending on the oxidation or reduction of sulphonated indigos, and the acetic-sulphuric acid method of Möhlau and Zimmermann.

The preparation of pure indigotin.—The fundamental objection raised by Bloxam (*loc. cit.*) to all the methods of indigotin estimation hitherto described is that there is no evidence that they have been founded upon application of the methods to pure indigotin as a standard: a fact which he suggests has been due to the difficulty of obtaining the substance in a pure condition. We have not experienced this difficulty. We have relied, throughout the work to be described, on the estimation of the nitrogen content as a criterion of purity of the indigotin used as our standard. The existence of an isomeric substance as an impurity has, therefore, not been totally excluded, but is rendered exceedingly improbable by the fact that analytical results, agreeing substantially

with the indigotin content indicated by estimation of the nitrogen, have been obtained with all the methods used.

Average Bengal indigos containing no indirubin were used as raw material for the preparation of pure indigotin, and were preliminarily purified in either of the two following ways:—

1. The finely powdered indigo was intimately mixed with plaster of Paris and water, and spread out in thin layers on tin sheets. When dry, gentle heat was applied until the indigotin sublimed on to the surface in the form of a velvety layer of crystals. Two nitrogen estimations of crystals obtained in this way gave N = 10·49 and 10·448 per cent. (mean value 10·469), corresponding with an indigotin content of 97·88 per cent.

2. The finely powdered indigo was suspended in lime water, and reduced with sodium hyposulphite, the solution of indigo-white re-oxidised by agitation with air, and the precipitated indigotin filtered off and washed; this was then boiled with hydrochloric acid and again filtered off and thoroughly washed. The substance thus obtained showed on analysis by the permanganate method (next column) a content of 93 per cent. indigotin.

Approximately pure indigotin obtained by either of these methods was further purified by dissolving the substance in a mixture of 100 parts glacial acetic acid and 4 parts sulphuric acid, and hydrolysing the indigotin monosulphate formed by water in the manner described by Möhlau and Zimmermann (*loc. cit.*); the precipitated indigotin was thoroughly washed and dried. Five nitrogen estimations of the product obtained in this way gave as a mean value N = 10·615, corresponding with 99·33 per cent. indigotin.

Attempts to isolate the impurities occurring in natural indigo.—It appeared to us that a much more real difficulty in checking the accuracy of the various methods of indigo analysis than that of obtaining pure indigotin lay in the direction of obtaining the naturally occurring impurities of commercial indigo free from indigotin, so that their effect on the methods could be directly traced. The ideal way of doing this would be to obtain a selective solvent for indigotin, so that the whole of the substance could be extracted from commercial indigo, and the impurities be left intact. A large number of indigotin solvents, including naphthalene, nitrobenzene, aniline, and phenol, were experimented with to this end, but in no case could the whole of the indigotin be extracted, whilst substances other than indigotin were invariably removed by the solvent. This method had, therefore, to be abandoned.

A second attempt to obtain the impurities free from indigotin was made by adopting the principle involved in the method of Möhlau and Zimmermann for the analysis of indigo, but it failed. Some other attempts were made, but were equally unsuccessful.

Finding this an apparently impossible task when starting from finished indigo, we had recourse to the indigo plant as a source of the impurities. Indigo is manufactured by steeping the plant in water for several hours, and oxidising the infusion with air, whereby the dye separates out, and settles to the bottom of the vessel in which the operation is conducted; the supernatant liquid is then run off and the indigo collected. This supernatant liquid contains a great deal of matter in solution, and it seemed probable that if these dissolved substances could be separated from the waste water, they would be of a very similar nature to those precipitated with the indigotin, and eventually constituting the impurities we were desirous of isolating. This was easily accomplished by evaporating the liquid to small bulk, and the brown bodies precipitated were found, on sulphonation and testing in the manner previously described, to behave exactly like the impurities of finished indigo. They were used as impurities in testing some of the methods of analysis to be described, but the idea only occurred to us late in the manufacturing season, and sufficient material could not be obtained to extend the principle to all the methods investigated; we hope to do so during the next season. Meanwhile we have had recourse to the use of obviously artificial impurities as diluents for pure indigotin. Starch and vegetable gluten have been selected as being of approximately the same type of bodies as those occurring in natural indigo, and have been used in the particular manner which the method under investigation demanded.

Indirubin.—The occurrence of indirubin as a constituent of natural indigo has been disputed by Bloxam (*loc. cit.*); but we have not been able to confirm his observations. On the contrary, the investigation into the nature of the red bodies existing in some indigos, at present in progress in this laboratory, has not only shown that indirubin is a very common constituent of natural indigo, but also that its formation from the indigo plant can be very easily explained. Being isomeric with indigotin, it behaves in a sufficiently similar manner towards reagents to profoundly affect methods for the estimation of that substance, and we have therefore thought it of value to trace its effect on the processes we have examined separately from that of other impurities. Synthetic indirubin showing a nitrogen content of 10·06 per cent. (corresponding with 94·275 per cent. indirubin) has been used for this purpose, sufficient natural indirubin not being available.

Methods depending on the oxidation of sulphonated indigos.—Of these methods only those in which potassium permanganate is used as an oxidising agent are reliable, and only these are at all generally used.

Rawson's method.—A full description of the permanganate method as worked out by Rawson will be found in that author's papers (J. Soc. Dyers and Colourists, 1885, **1**, 74; this J., 1899, **18**, 251) and in "A Dictionary of Dyes and Mordants," by Rawson, Gardner, and Laycock. Briefly, the method consists in sulphonating the indigo by heating with pure sulphuric acid at 70°—80° for an hour, diluting, purifying the solution of indigotindisulphonic acid obtained by addition of barium chloride, and titrating a known volume of the solution, diluted with a large column of water, with approximately N/50 permanganate until all the blue colour disappears.

The method is open to criticism from three points of view:—(1) The reaction involved may not be a quantitative one; (2) the method of purifying the solution may lead to the precipitation of indigotin; (3) the impurities present may not be entirely removed by the precipitant and may affect the permanganate. We have investigated the method from each of these points of view.

Bloxam (*loc. cit.*) lays great stress upon the objection, first raised by him, that the reaction is not a quantitative one, and points out that, even if pure indigotin be dealt with, and the conditions laid down by Rawson be strictly adhered to, the reaction is a progressive one and no definite end point can be arrived at in titration. Our experience of this method has extended over a good many years, and we have never found this objection to hold; with a little practice the end point is absolutely sharp and distinct even when an impure indigo is used, whilst with pure indigotin no previous practice should be necessary. The reaction is admittedly a progressive one, and it is therefore necessary to conduct the titration rapidly and to take the disappearance of the blue colour as an indication of its completion: for this reason Bloxam's experiments on the subject are irrelevant. The exact reaction which is measured by the process is a matter for future investigation; it is clear that it is not represented by the equation given by Rawson as expressing the interaction of concentrated solutions of permanganate and indigotindisulphonic acid, since, as Rawson himself points out, the equation does not indicate the proportion found to exist between these two bodies when they react in dilute solution; but the fact that the reaction measured is a quantitative one, and that the relation between the reacting substances is accurately expressed by that found by Rawson (2·373 indigotin = 1 permanganate) is demonstrated by the following results obtained by an application of the method to pure indigotin. No barium chloride or other purifying agent was used in these tests, since no impurities were present.

Nitrogen per cent. in substance.	Indigotin per cent., calculated from nitrogen content.	Grms. of substance sulphonated, solution made up to 500 c.c.	Volume of solution titrated in c.c.	Titre of permanganate.	Volume of permanganate required in c.c.	Indigotin per cent. in substance, calculated from permanganate using Rawson's factor.
10·59	99·1	0·3	25	N/49·45	10·05	99·39
10·59	99·1	0·3	25	N/49·45	10·00	99·9
10·59	99·1	0·3	25	N/49·45	10·05	99·39
10·59	99·1	0·5	25	N/49·45	16·7	99·1
10·62	99·4	0·5	25	N/50·20	16·5	99·39

Method of sulphonation.—It is clear from the above table that Rawson's method of sulphonation and titration leads to correct results. The sulphonating process is, however, somewhat troublesome, and we have investigated a more rapid and convenient method of conducting this operation suggested by Dr. Schulten, of Calcutta, and used in his laboratory. The method differs from that of Rawson, in that small glass-stoppered bottles, which can be easily and rapidly shaken, are used instead of open crucibles, which require frequent stirring; and the sulphonation is conducted at the temperature of a briskly boiling water-bath for a quarter of an hour, instead of at 70°—80° for an hour. Pure indigotin, sulphonated in this way, has been found to give correct analytical results when diluted and titrated in accordance with Rawson's recommendations. Some results obtained by its application to commercial indigos of varying qualities are given later (page 734).

Method of purifying the solution of indigotindisulphonic acid.—In applying the permanganate method to the analysis of commercial indigos it is always necessary to employ some method of removing the undissolved impurities which remain in suspension when the solution of indigotindisulphonic acid in sulphuric acid is diluted with water; otherwise the end point of the titration is masked and the result obtained too high. Rawson's methods of filtering and of salting out the sodium salt of the acid, have now been entirely replaced by the same author's plan of producing a precipitate of barium sulphate in the solution by the addition of barium chloride, whereby the impurities are carried down; of this method Rawson states, "Tests made with pure indigotin show that no colouring matter is precipitated by the barium chloride" ("Dictionary of Dyes and Mordants"). Owing to the insoluble nature of the barium salt of indigotindisulphonic acid this seemed antecedently improbable, though the amount of the salt precipitated might conceivably be too small to affect the analysis due to the greater insolubility of barium sulphate. The following experiments were carried out on this point:

Four samples of a pure natural indigotin, showing by estimation of their nitrogen a content of 99·4 per cent. indigotin, were sulphonated. The solutions were made up to 500 c.c., without the addition of barium chloride, and 25 c.c. titrated with permanganate; 10 c.c. of a 20 per cent. solution of barium chloride were then added to each of the solutions, the volumes made up again to 500 c.c., and after thoroughly shaking and allowing the solutions to remain for the precipitates to settle, 25 c.c. were again titrated, the results obtained being calculated back to the volume of the original solution (*i.e.*, multiplied by 20/19). This process was repeated a second time, making the solution up to 500 c.c., and again calculating back from the titration of 25 c.c. to the volume of the first solution. The results obtained were identical in the case of each series of experiments, and were as follows:—

	Percentage content of indigotin.
Without addition of barium chloride	99·39
With addition of 10 c.c. of 20 per cent. barium chloride solution	95·78
With addition of 20 c.c. of 20 per cent. barium chloride solution	92·77

There thus appears to be a distinct precipitation of indigotin and consequent drop in the amount estimated. This was confirmed with two samples of synthetic indigo made by the Badische Anilin und Soda Fabrik, in which cases the effect of further addition of barium chloride was tried and the following results obtained:—

Percentage content of indigotin.

	B.A.S.F. "Indigo Pure" 1898.	B.A.S.F. "Indigo Pure" 1905.
Without addition of barium chloride	98·1	93·7
With addition of 10 c.c. of of 20 per cent. barium chloride solution	96·8	92·1
With addition of 20 c.c. of 20 per cent. barium chloride solution	95·2	90·3
With addition of 30 c.c. of 20 per cent. barium chloride solution	93·3	88·1

It is clear therefore that an appreciable amount of indigotin is precipitated by the addition of the quantity of barium chloride recommended by Rawson, and that the precipitation is progressive with successive additions of the precipitant.

Grossmann's method.—An alternative method of removing the suspended impurities from the diluted solution of indigotindisulphonic acid has been proposed by Grossmann (this J., 1905, **24**, 308). This consists in neutralising the solution with pure calcium carbonate, whereby a heavy precipitate of calcium sulphate is formed which carries down all suspended impurities, whilst, according to the author of the method, the neutralisation of the solution leads to the precipitation of other impurities which would otherwise remain dissolved in the dilute acid. In this latter respect, the author claims that his method of purification has advantages over that of Rawson.

This method seemed to us open to the same objection as we had found to exist when barium chloride was used as a precipitant: that indigotin would inevitably be carried down as the disulphonic acid salt of the base of the substance used for precipitation, in this case calcium. On applying the method to a specimen of pure natural indigotin, showing by estimation of its nitrogen and by titration with permanganate without addition of a precipitant, a content of 99·35 per cent. indigotin, the result indicated a content of only 96·0 per cent.; showing that 3·35 per cent. of the indigotin present had been carried down by the calcium carbonate.

To confirm this explanation of the low result obtained, the following experiments were carried out:—1 grm. of each of three different indigos of high purity was sulphonated and the solutions made up to 1 litre; five portions of 100 c.c. each were then withdrawn from each of these solutions and varying quantities of calcium carbonate added to each, after which they were made up to 500 c.c., and the precipitates having been allowed to settle, 249 c.c. titrated with permanganate (1 c.c. being allowed for the bulk of the precipitate, *vide* Grossmann). The remainder of these solutions were then made up again to 500 c.c. in each case, well shaken, and, after allowing the precipitates to settle, 249 c.c. were again withdrawn for titration. The results were calculated back to the weight of the indigo originally taken, and the following results obtained:—

Amount of calcium carbonate added.	Indigo A (natural) containing 96·96 per cent. indigotin.		Indigo B (synthetic) containing 98·1 per cent. indigotin.		Indigo C (synthetic) containing 99·1 per cent. indigotin.	
	1st titration.	2nd titration.	1st titration.	2nd titration.	1st titration.	2nd titration.
4 grms. (solution acid).....	96·96	96·96	97·8	98·1	95·4	98·1
4·5 grms. (solution acid).....	95·75	96·65	96·6	97·2	92·7	99·3
5 grms. (solution slightly acid)....	94·53	97·26	95·7	98·4	91·8	100·2
5·5 grms. (solution neutral).....	92·71	97·86	95·7	98·4	92·4	99·0
6 grms. (solution neutral).....	93·0	97·5	95·7	98·4	92·4	100·2

These results clearly indicate that indigotin is carried down by the calcium carbonate added and that the action is progressive with successive additions of the precipitant up to the point of neutrality. This is shown not only by the falling off in the amount of indigotin estimated in successive experiments in the first series of titrations, but also by the corresponding gradual increase in the amount estimated in the second series, this no doubt being due to the redissolution of the precipitated calcium indigotindisulphonate on addition of more water. In this way the results obtained considerably exceed the truth in some instances in the second series of titrations. This method of purifying the solution of indigotindisulphonic acid is therefore liable to lead to very erroneous results when applied to high grade indigos, but the error is not so large as that inherent in the barium chloride method, due to the solubility of the calcium salt being greater than that of the barium salt, and it will be seen in the table on page 734 that when applied to indigos of average commercial purity it is very small indeed.

Precipitation of impurities by barium sulphate.—We have found that if a precipitate of barium sulphate is freshly formed out of contact with the solution of indigotindisulphonic acid, and added to the latter as such, the precipitation of indigotin does not take place, and, by thoroughly shaking the barium sulphate in the solution, it is as efficiently purified as by either of the methods previously described.

In the following experiments 10 c.c. of a 20 per cent. solution of barium chloride were placed in the 500 c.c. flask and barium sulphate precipitated by addition of an excess of sulphuric acid before the addition of the solution of indigotindisulphonic acid. The solution was then made up to volume, well shaken, and the precipitate allowed to settle, and 25 c.c. titrated with permanganate as in the previous experiments.

Percentage content of indigotin.

	Natural indigotin.	B.A.S.F. "indigo pure," 1905.
Without addition of barium chloride	99·5	93·7
With addition of barium sulphate precipitated from 10 c.c. of 20 per cent. barium chloride solution	99·7	93·91

A large number of commercial indigos were analysed by titration with permanganate to compare this method of purifying the solution of the sulphonic acid with that of Rawson. The following are a few of the results obtained :—

Percentage content of indigotin.

With addition of 10 c.c of 20 per cent. barium chloride solution (Rawson).	With addition of barium sulphate precipitated from 10 c.c. of 20 per cent. barium chloride solution.
73·9	75·11
71·0	73·35
69·24	69·82
58·68	60·70
53·1	55·2

Thus a higher result is obtained in every case by precipitating the barium sulphate before the addition of the indigotindisulphonic acid solution. This was found to be true of every indigo analysed. The higher results could not be accounted for by impurities remaining in suspension, since portions of the solutions were filtered simultaneously with the performance of the titrations, and no traces of impurity were found in suspension. The end point in titration was perfectly sharp and clear, whilst the fact that higher results were obtained with this method when dealing with pure indigotin confirmed the explanation that they were due to the precipitation of indigotin when Rawson's method of purification was used.

We have therefore adopted the barium sulphate method of purification, and have used it in the following experiments on the influence of dissolved impurities on the permanganate method.

Effect of dissolved impurities.—In titrating a solution of a sulphonated commercial indigo, purified by either of the above-described methods with permanganate, a very much darker end point is obtained than if a pure indigotin is dealt with, showing that certain impurities are left in solution in the dilute acid, and are therefore not carried down by precipitants. It was with a view to tracing the effect of these bodies that the attempts, previously described, to obtain the natural impurities free from indigotin were made. It has been shown that these attempts were unsuccessful, but that other bodies very closely resembling them were obtained by evaporation of the waste water from indigo manufacture. In the following experiments a solution of such impurities was made by sulphonating, diluting, and purifying as previously described, under the identical conditions used for indigo. Three different specimens of impurities, derived from three different samples of waste water, were employed, and in each case a known weight was taken, and the solution made up to known volume. A solution of "B.A.S.F. Indigo pure" containing 98·4 per cent. indigotin was made in the same manner but without purification, and known volumes of this solution were mixed with known volumes of each of the solutions of impurities in such proportions as together represented indigos of various degrees of purity. The mixed solutions were then titrated with permanganate, and the following results obtained :—

Percentage content of indigotin in mixture.

By calculation.	By experiment (Impurities A.)	By experiment (Impurities B).	By experiment (Impurities C).	Average. Percentage error.
73·8	74·7	74·4	73·9	0·5
61·5	62·4	62·4	62·4	0·9
49·2	50·4	50·4	50·3	1·16
24·6	27·0	27·0	26·96	2·39

The error is thus seen to be progressive with decreasing purity of the indigo, amounting, in the case of an indigo of average commercial purity (60 per cent.), to about 1 per cent.

To confirm these results, a mixture of equal weights of starch and vegetable gluten was used as impurity, and the experiments carried out exactly as before. The following figures were obtained :—

Percentage content of indigotin in mixture.

By calculation.	By experiment.	Average percentage error.
74·25	74·4	0·15
49·50	49·8	0·3
24·75	25·05	0·3

Here again the error is found to increase with decreasing purity, but it is considerably smaller than in the previous set of experiments for indigo of like purity. The end points in titration were also considerably lighter and brighter than in dealing with natural indigos of the same degree of purity. Experimental facts obtained indicate that starch and gluten do not provide impurities of a type truly representative of those of natural indigo, but the results are worthy of record as showing how little effect such bodies have upon the method of analysis.

Effect of indirubin.—A solution of sulphonated indirubin was made exactly as described for the solution of the impurities dealt with in the preceding paragraph. Volumes of this solution were then mixed with volumes of a solution of pure natural indigotin so as to represent indigos of known indirubin content and titrated as before. The following results were obtained :—

Percentage content of indigotin in mixture.

By calculation.	By experiment.	Percentage error due to indirubin.
96·5	97·62	1·12
94·0	94·97	0·97
89·0	91·62	2·62

Thus a very small proportion of indirubin affects the results considerably, but concordant results within the limits of accuracy shown in the table can be obtained with practice by conducting the titration until all the blue colour is destroyed.

Methods depending on reduction of sulphonated indigo.—The principle underlying these methods is the quantitative reduction of indigotindisulphonic acid to the corresponding leuco compound by titration with a reducing agent until all the blue colour is destroyed. It is therefore necessary to conduct the operations out of contact with air so that the apparatus required is somewhat complicated.

Hyposulphite method.—Sodium hyposulphite has been most commonly used as a reducing agent, and a full description of a method involving its use will be found in "A Dictionary of Dyes and Mordants," by Rawson, Gardner, and Laycock. We have found the method to give correct results when applied to pure indigotin, but the method of standardisation of the hyposulphite with ammoniacal copper sulphate is troublesome: the solution of hyposulphite is exceedingly unstable, and it is necessary to carefully expel all air from the solution to be titrated, and to cool it thoroughly out of contact with air before titration, if correct results are to be obtained. The following experiments were carried out to trace the effect of dissolved impurities on the method. The substances derived from waste water in indigo manufacture were used as impurities, and the solutions made up for titration in exactly the same way as previously described in testing their effect on the permanganate method. The following results were obtained :—

Percentage content of indigotin in mixture.

By calculation.	By experiment.	Percentage error.
74·475	75·95	1·475
49·65	51·26	1·61
24·825	27·26	2·436

The end points in titration were not very clear, and the error is no doubt to some extent due to the uncertainty of determining the exact completion of the reaction. This was also found to be the case in dealing with ordinary commercial indigos, but fairly accurate results were obtained by the application of Grossmann's method of purification to the solutions before titrating with hyposulphite (see table, page 734).

Effect of indirubin.—It is stated in "A Dictionary of Dyes and Mordants" (*loc. cit.*) that the hyposulphite method does not estimate indirubin in the presence of indigotin. With a view to determining the effect of this substance on the determination of indigotin, a similar series of experiments to those described for tracing the effect of indirubin on the permanganate method was carried out, and the following results obtained :—

Percentage of indigotin in mixture.

By calculation.	By experiment.	Percentage error.
96·5	99	2·5
94·0	99	5·0
89·0	99	10·0

The error due to indirubin is thus in every case equal to the amount of that substance added. The end points in titration were perfectly sharp and the solutions obtained at the conclusion of the operation of a brownish-yellow colour exactly like that obtained when pure indigotin is estimated. It is evident, therefore, that the method determines the two constituents simultaneously.

To confirm this the method was applied to a specimen of pure indirubin (N = 10·06 per cent., corresponding to 94·275 per cent. indirubin), and was found to show a content of 94·5 per cent. indirubin, coinciding very nearly with the truth.

Titanous chloride method.—This method has recently been described by Knecht (J. Soc. Dyers and Colourists, 1905, 21, 292), and depends upon precisely the same reaction as the hyposulphite method. It has the advantages over the latter method, however, that the solution of the reagent is more stable, the standardisation is more easily accomplished, the end point in titration (using Grossmann's method of purifying the sulphonic acid solution) is sharper, and the solution may be titrated warm without any ill-effect. The method gives correct results with pure indigotin, but, as is pointed out by its author, no clear end point in titration can be obtained with an impure indigo unless the solution to be titrated is purified by Grossmann's method. The results obtained are therefore subject to the same errors as we have show to be inherent in this means of purification, but these are small when indigos of average quality are dealt with (see table, page 734). The effect of starch and gluten added as impurities to pure indigotin is shown in the following table :—

Percentage content of indigotin in mixture.

By calculation.	By experiment.	Percentage error.
74·475	74·66	0·185
49·65	49·7	0·05
24·825	24·88	0·055

The error introduced by these impurities is thus very slight.

We have confirmed the author's statement that this method determines indirubin together with indigotin,

having obtained by its use a precisely similar set of figures to those above showing the effect of indirubin on the hyposulphite method. Indirubin is also correctly estimated alone.

Acetic-sulphuric acid method.—This method is founded on the formation of the monosulphate of indigotin in glacial acetic acid solution, its hydrolysis by pouring the solution into water, and weighing of the precipitated indigotin as such. The method of formation of the monosulphate was first described by Binz and Kufferath (Annalen, 1902, **325**, 196), and its application as a means of analysis by Möhlau and Zimmermann (Zeit. Farb. Text. Chem., 1903, **10**, 189). Bloxam (*loc. cit.*) shows that a method of quantitative analysis of indigo cannot be founded upon the use of the mixture of acetic and sulphuric acids used by Binz and Kufferath, containing five parts of the former acid to one part of the latter, since the product derived from a commercial indigo by pouring the solution obtained into water is not pure indigotin, even after thorough washing with alcohol. Pure indigotin is, however, obtained if a fairly pure specimen of indigo is used as a starting point. We have confirmed these observations and have experimented with the modification suggested by Möhlau and Zimmermann (*loc. cit.*), which mainly consists in using a mixture of acetic and sulphuric acids containing only four parts of the latter acid to 100 of the former. We have found this method to give correct results with pure indigotin, and with indigos showing a content of over 90 per cent. of this constituent, the precipitate obtained containing over 99 per cent. of indigotin, as has already been shown in describing our methods of obtaining this substance in a pure condition. In dealing with commercial indigos the operations of sulphate formation and hydrolysis must be repeated many times before pure indigotin is obtained as a precipitate, and the manipulations necessary are very liable to lead to errors, which assume a considerable magnitude when calculated on to the small weight of substance with which it is requisite to work. We have found that as much as 0·25 grm. of indigo can be safely dealt with by this method, using the quantity of mixed acids recommended by its authors, but it is not advisable to exceed that amount. The precipitates obtained should always be thoroughly washed with alcohol to remove red impurities which are carried down with the indigotin. In the analyses of commercial indigos by this method, given in table above, these precautions were adopted and precipitates ultimately obtained showing a content of 99·8 per cent. indigotin by titration with permanganate. The procedure is, however, tedious, and the method does not recommend itself.

Effect of indirubin.—A set of experiments, similar to those carried out to trace the effect of this constituent on the other methods of analysis, gave the following results:—

Percentage content of indigotin in mixture.

By calculation.	By experiment.	Percentage error.
96·5	97·85	1·35
94·0	95·6	1·6
89·0	92·85	3·85

Thus the indirubin is partially, but not wholly, estimated by the method, being soluble to some extent in dilute acetic acid; correct results for indigotin can, therefore, not be obtained in the presence of this constituent.

Application of the methods investigated to commercial indigos.—In the following table we have summarised the results obtained in estimating the indigotin content of six typical Bengal indigos. All the results are expressed on dry material and are the mean of duplicate experiments.

	Permanganate methods.				Reduction methods using Grossmann's of purification.		Acetic-sulphuric acid method of Möhlau and Zimmermann.
	Sulphonation by Rawson's method.			Sulphonation in boiling water-bath and purification of solution by barium sulphate.			
	Purification of solution by barium chloride.	Purification of solution by barium sulphate.	Purification of solution by Grossmann's method.		Hyposulphite method.	Titanous chloride method.	
I.	75·14	77·26	77·26	77·0	76·26	77·09	75·8
II.	68·81	70·31	69·71	70·5	70·25	69·77	70·0
III.	68·81	69·11	68·81	69·8	68·95	68·99	70·37
IV.	60·36	61·86	61·26	62·4	61·63	61·41	62·35
V.	54·92	55·53	54·92	55·8	54·32	54·88	55·3
VI.	45·87	47·08	47·08	47·2	47·01	47·3	46·4

The table shows that fairly concordant results are obtained with all the methods investigated except that in which barium chloride is used as a precipitant. The permanganate methods are a good deal simpler, and more rapid in execution than the reduction or gravimetric methods, and we were unable to find any superiority in the sharpness of the end point when applying Grossmann's principle of purification to the solutions titrated with permanganate, whilst we have shown that the use of calcium carbonate, besides requiring more manipulation than that of barium sulphate, involves a small error. Purification with calcium carbonate is essential to reduction methods, and one of these should be used in estimating indigotin in indigos containing indirubin, the latter constituent being then separately determined by a special method and deducted. For all other indigos the highest accuracy is combined with the most rapid working by proceeding as follows:—0·5 grm. of finely-powdered indigo is placed in a small, narrow-necked stoppered bottle, and mixed with a few Bohemian garnets; 20 c.c. of pure concentrated sulphuric acid are added, and the bottle, with its stopper removed, placed in a shallow water-bath containing just enough water to cover the depth of acid in the bottle. The bath is now brought to the boil, and when briskly boiling, the stopper is replaced in the bottle, which is shaken periodically for 15 minutes. At the end of this time the bottle is removed from the water-bath, and allowed to remain in cold water with its stopper removed until the contents are cool. These are then transferred to a 500 c.c. flask in which 10 c.c. of a 20 per cent. barium chloride solution and sufficient sulphuric acid to precipitate all the barium has previously been placed, and the whole made up to volume, well shaken, and set aside for the precipitate to settle for one hour. An aliquot part of the supernatant liquid is then titrated with approximately N/50 permanganate, and the result calculated on the basis that 1 c.c. N/50 permanganate is equivalent to 0·0015 grm. indigotin.

The determination of indigotin in indigo-yielding plants.—The work now in progress in India on the improvement of the cultivation and manufacture of indigo has rendered it imperative that a reliable method of estimating the amount of indigotin a given plant is capable of yielding should be available. Such a method was devised by Rawson in 1900, and an account of it published in his "Report on the Cultivation and Manufacture of Indigo," in 1904. The method consists in extracting 20 grms. of leaf (in which all the colour-yielding principle resides) with boiling water, straining off the leaves, and precipitating the indigotin from the solution of the glucoside so obtained by the addition of 5 c.c. of hydrochloric acid (containing 20 per cent. HCl) and 40 c.c. of a 5 per cent. solution of ammonium persulphate. The

[illegible] with the case of an (Trans. Chem. Soc., 1904, 85, 877) that this method of precipitating the indigotin from an extract of the indigo plant did not give the same result as was obtained by fermenting the extract with the enzyme extracted from indigo leaves and oxidising the fermented liquid with air, a larger amount of indigotin being invariably obtained by the latter method. We have investigated the cause of this anomaly, and, as a preliminary, have submitted the fermentation method to a careful examination, with a view to determining the accuracy in the results obtained by its application. The plant extract and enzyme solution were prepared exactly as described in the previous paper (*loc. cit.*) and the same methods for determining the completion of the fermentation process and for oxidising the solutions have been adopted. The following experiments were carried out:—

Experiment A.—450 c.c. of extract were fermented with 180 c.c. of enzyme solution, and the fermentation being complete after two hours and forty minutes, two portions of 280 c.c. each were withdrawn and oxidised, and the indigotin precipitated, determined in each case (I. and II.); 450 c.c. of the same extract were fermented with 75 c.c. of enzyme solution, in which case the fermentation process took four hours and forty minutes for completion, and two portions of 245 c.c. each were then withdrawn from this solution, oxidised, and the indigotin determined (III. and IV.).

Experiment B.—440 c.c. of extract were fermented with 220 c.c. of enzyme solution, and after four hours, the fermentation being complete, two portions of 300 c.c. each were withdrawn, oxidised, and the indigotin estimated (I. and II.); 440 c.c. of the same extract were fermented with 110 c.c. of enzyme solution, and on completion of the fermentation after seven hours, two portions of 250 c.c. each were withdrawn, oxidised, and indigotin determined (III. and IV.). The following results, expressed as the amount of indigotin obtained from 200 c.c. of extract in each case were obtained:—

	I.	II.	III.	IV.
	grm.	grm.	grm.	grm.
Experiment A.	0·1666	0·1675	0·1687	0·1665
Experiment B.	0·100	0·100	0·100	0·098

It is thus shown that the results obtained by fermenting an extract of plant under varying conditions are concordant, and it is therefore probable that the figures obtained represent the true amount of indigotin obtainable from the extract.

Attempts were accordingly made to bring the chemical method of precipitation into line with the fermentation method. It was thought probable that the difference was due to the employment of an excess of persulphuric acid in Bergtheil's method, since indigotin is oxidised and dissolved by an excess of this reagent, and the amount used [illegible] far exceeds the requirements on the assumption that it was only oxidised to indoxyl. We have found this to be the case, and that results coinciding exactly with those obtained by fermentation may be obtained by [illegible] as follows:—The extract of leaf is made as [illegible] Extracts were being taken to keep the [illegible] possible. The extract is then [illegible] and [illegible] as previously described. We have found that [illegible] with 30 grms. of lead (i.e., of 2 /) was sufficient for complete precipitation of the indigotin. This solution is the maximum required.

The identity of the results obtained by the [illegible] and by fermentation with enzyme is shown by the following experiments:—

Experiment A.—The quantity of indigotin [illegible] from two portions of extract of 150 c.c. each was determined by the persulphuric acid method (I. and II.); 220 c.c. of the same extract were fermented with 110 c.c. of enzyme solution, and two portions of 150 c.c. each were withdrawn, oxidised, and indigotin precipitated and determined when fermentation was complete (III. and IV.).

Experiment B.—The indigotin obtainable from two portions of extract of 150 c.c. each was determined by persulphuric acid (I. and II.), and 175 c.c. of the same extract were fermented with the same volume of enzyme solution, and the indigotin precipitated by acidifying determined in 300 c.c. of the fermented solution (III. and IV.). The following results, expressed as the amount of indigotin obtained from 100 c.c. of extract, were obtained:—

	Persulphuric acid method.		Fermentation.	
		grm.		grm.
Experiment A	I.	0·0847	III.	0·0843
	II.	0·0852	IV.	0·0822
Experiment B	I.	0·0950	III.	0·0950
	II.	0·0950	IV.	0·0930

The accuracy of the persulphuric acid method as a means of determining the amount of [illegible] from an extract of indigo plant is thus established.

Yorkshire Section.

Meeting held at the University, Leeds, on Monday, June 18th, 1906.

PROF. A. G. GREEN IN THE CHAIR.

THE ANALYSIS OF INDIGO.

BY W. FORTESCUE HARRISON.

Introductory.—The author was employed [illegible] —1904) in research work on plants [illegible] Seed Station (Bengal), and during the [illegible] tion was made of the results obtained.

In October, 1903, arrangements were [illegible] Government of India that the work should [illegible] in the Cloth Testing Laboratory [illegible] Leeds, under the personal [illegible] This [illegible] of the [illegible] the [illegible]

possible to develop an accurate method of analysis for both pure indigotin and crude indigo, there would become available a large amount of information for planters and dyers using plant indigo.

For here was material on which could be determined the daily yield of indigotin, obtained in an ordinary factory from known weights of green plant, throughout the period of manufacture; and, in addition, the results attained by the use of manures upon the experimental plots at Dalsingh Serai.

In order to be able to judge of the accuracy of the methods already in existence for the analysis of indigo, it was absolutely necessary to be able to prepare pure indigotin in quantity for use as a standard. (See this J., 1904, 746—747). Two methods were available for this purpose:—

(*a*) *Recrystallisation from nitrobenzene.*—This process proved somewhat laborious, some 30 grms. only being obtained after a week's work. Moreover, later experiments tended to throw doubt on the purity of the product obtained by this method.

(*b*) *Sublimation under diminished pressure.*—This method has already been briefly described (Chem. Soc. Trans., 1905, **87**, 983). A slight modification was now made by immersing the Jena flask in a bath of fusible metal, the level of the fusible metal just coinciding with the upper surface of the indigo within the flask. A square of asbestos-cardboard was so arranged that the portion of the flask, between the level of the fusible metal and the asbestos-cardboard was raised to such a temperature that only indigotin vapour was there present, and this zone of the flask remained quite clean at the close of the operation, the sublimate being deposited in the upper portion of the flask above the asbestos card.

Sublimation was observed to commence when a thermometer (filled with mercury under pressure of nitrogen) placed in the fusible metal indicated 300° C., the sublimation being finally effected between 370° and 390° C. The sublimate was beautifully crystalline and quite pure.* This statement is considered necessary, as Knecht states (J. Soc. Dyers and Colourists, 1904, **20**, 97). "Without going into any detail with regard to the work we carried out on this subject, I may say that, of the various methods of purification tried, sublimation under reduced pressure, though yielding large crystals, gave the least pure product."

In this fashion indigotin can be obtained in any desired quantity. Using the "B.A.S.F. rein" as source, 100 grms. can easily be prepared in a day. Examination and analysis showed: (*a*) That it contained no ash; (*b*) that it contained no impurity which could be removed by solvents; (*c*) on analysis it yielded theoretical figures when tested by the methods of analysis later described in detail (see p. 741).

An Examination of the Practicability of the Methods which have been proposed for the Analysis of Indigo.

Section I.—Methods involving the use of potassium permanganate.

This method, originally introduced by Mohr (Dingl. pol. J., cxxxii. 363), has been modified by Rawson, and has been examined critically by the present writer (Chem. Soc. Trans., 1905, **87**, 984). Although this method may be of use for commercial purposes in determining the relative merits between two samples of indigo, it is generally admitted that the process cannot, as it stands, be used for accurate determination of the indigotin percentage of a crude indigo. (See also this J., 1904, 747.) This statement is sustained after a critical examination of the improvements suggested by Rawson and by Grossmann. ("A Manual of Dyeing," Knecht, Rawson and Lowenthal; Griffin, London, 1901. "An Improved Method of Indigo-testing," Grossmann; this J., 1905, 308.) These processes, although no doubt effecting a clearer end-point of the reaction, entail at the same time losses of indigotin; for the precipitates given by barium chloride and calcium carbonate, respectively, are always blue coloured. Feeling that this might be due either to some error in the manipulation, or to some fault in the process of sulphonation, it was decided to prepare the various sulphonic acids of indigotin in a pure condition, and to study the behaviour of their barium and calcium salts, for it was considered probable that failure was due to the degree of sulphonation being too low. In this case it might be possible, at a higher degree of sulphonation, to throw down the impurities by the action of calcium carbonate without loss of the indigotin content of the solution.

I.—*Preparation of Potassium Indigotinmonosulphonate.*

One part of indigo (B.A.S.F. rein), 20 parts of sulphuric acid (100 per cent.), and 10 parts of treated pure sand, were thoroughly mixed together, and allowed to stand for about one hour with frequent stirring. The progress of the reaction was tested from time to time by transferring a drop of the mixture into water. When a violet solution was obtained in hot water, the whole mass was poured into water, cooled, and the precipitate filtered off and pressed on a porous plate. It was then re-dissolved in a large volume of boiling water, and the potassium salt precipitated by the addition of potassium carbonate. The salt could not be obtained in a crystalline form, but it was purified by repeated solution in boiling water. On analysis, 0·3018 grm. of sulphonate gave 0·0656 grm. potassium sulphate,

K = 9·74 per cent. (theory = 10·26 per cent.);

0·2213 grm. of sulphonate gave 0·1396 grm. barium sulphate,

S = 8·50 per cent. (theory = 8·42 per cent.).

Indigotin could not be determined by titration with potassium permanganate owing to the slight solubility of the mono-sulphonic acid.

II.—*Preparation of Potassium Indigotindisulphonate.*

6 grms. of "indigo B.A.S.F.," 120 grms. of sulphuric acid (96 per cent.), and purified sand, were heated in the water oven for an hour and a half, the product was poured into water, and the solution filtered hot. To the filtrate potassium carbonate was added until the potassium salt was nearly all salted out. The temperature of the mother liquor was then raised to the boiling point, when solution took place, and on cooling the disulphonate separated as a crystalline precipitate, which was collected on the filter pump, and washed thoroughly, first with a solution of potassium acetate, and then with alcohol. It may be further purified by redissolving in boiling water, cooling, filtering off the precipitate and washing as before. As a result of analysis 0·3190 grm. of sulphonate gave 0·1029 grm. potassium sulphate, K = 14·46 per cent. (theory = 15·6 per cent.).

0·423 grm. of sulphonate gave 0·3884 grm. barium sulphate. S = 12·53 per cent. (theory = 12·85 per cent.).

Titration of indigotin by permanganate gave 51·68 per cent. (theory = 52·2 per cent.).

III.—*Preparation of Potassium Indigotintrisulphonate.*

10 grms. of "indigo B.A.S.F.," 100 grms. of fuming sulphuric acid (15 per cent. SO_3), and 100 grms. of purified sand, were heated together for three hours at 45°—55° C., with frequent stirring, and the product poured into water. The procedure for the isolation and purification of the potassium salt was similar to that given above for the disulphonate. Potassium indigotintrisulphonate crystallises well from hot water in very minute blue needles, thus

* In the Chem. Soc. Proc., 1904, **20**, 189, and in the full paper (Chem. Soc. Trans., 1905, **87**, 982), the author claimed priority of production of pure indigotin by sublimation as described. A paper has, however, recently been discovered, "The Molecular Weight of Indigo," by E. von Sommaruga. (Annalen, 1879, 195, 109), in which the author shows he prepared pure indigotin by sublimation of the refined natural product under diminished pressure, and subjected it to analysis.

wandering filtration and purification, easy. 0·2072 grm. of this sulphonate gave 0·1832 grm. potassium sulphate; hence K = 18·4 per cent. (theory = 18·0 per cent.).

0·2522 grm. gave 0·2868 grm. barium sulphate: S = 15·61 per cent. (theory = 15·57 per cent.).

By titration with permanganate the indigotin percentage was found to be 41·6 per cent. (theory = 42 per cent.)

IV.—*Preparation of Potassium Indigotintetrasulphonate.*

6 grms. of "indigo B.A.S.F." were stirred into a paste with sand and a few cubic centimeters of 100 per cent. sulphuric acid, to this was added 60 grms. of 50 per cent. fuming sulphuric acid, and the whole heated to 110° C. for half an hour with frequent stirring. The method of isolation and purification of the sulphonate is the same as that adopted for the trisulphonate. Potassium indigotintetrasulphonate crystallises exceedingly well from hot water in fairly large transparent red crystals. 0·2585 grm. of the sulphonate gave 0·1201 grm. potassium sulphate: K = 20·8 per cent. (theory = 21·25 per cent.).

0·2982 grm. of the sulphonate gave 0·387 grm. barium sulphate: S = 17·7 per cent. (theory = 17·4 per cent.).

Indigotin by titration with permanganate gave indigotin, 34·7 per cent. (theory = 35·15 per cent.).

Conditions under which the sulphonation of pure indigotin can be effected without loss.

It was now considered necessary to determine whether loss of indigotin was involved in the process of sulphonation. For, if sulphonation could not be effected without loss, then it would be obviously useless to try the Grossmann or other modes of removing the impurities from crude indigo, as the fault of loss on sulphonation would be a vital one. The only detailed information on this subject seems to be found in a paper by Wangerin and Vorländer on "The Titration of Indigotin with Hydrosulphite." (Zeits. f. Farben- und Textilchemie., 1902, 1, 281.) These authors state that 60 per cent. sulphuric acid does not sulphonate indigotin, even when used in great excess.

The ordinary concentrated (94 per cent.) acid, as is well known, dissolves indigotin without leaving any residue. With sufficient shaking, half an hour's heating at 95°—100° suffices with 10 volumes of 94 per cent. or stronger acid for sulphonation. The authors then proceed to determine by titration with hydrosulphite how much indigotin is lost by oxidation in sulphonating with sulphuric acid of various strengths for different times. Employing as the temperature limits 95°—100° C., they state that loss occurs with acid of so low strength as 94 per cent. when heating is continued for half an hour. Acid of 100 per cent. is stated to give rise to a loss of 2·4 per cent. indigotin on heating for one hour at 95°—100° C. Acid of 5 per cent. fuming is stated to give rise to losses of indigotin ranging from 2 per cent. to 14·7 per cent., according to the time of heating (half an hour to one hour at 95°—100° C.). It is not possible to agree with these statements of Wangerin and Vorländer, for the figures given in the following table show that with pure indigotin, no loss was experienced on using 20 per cent. fuming sulphuric acid for three-quarters of an hour at 97° C.

In the present sulphonation experiments the indigotin, placed in a small beaker, was first mixed with sand (purified by exhaustive treatment at the boiling point with strong sulphuric acid, and a trace of nitric acid, to remove iron and organic matter, and finally washed and dried at 140° C.) and then treated with acid and placed in the water oven, the mixture being stirred at regular intervals. In this way, pure indigotin can be converted almost entirely into the tetrasulphonic acid in half an hour by treatment with 20 per cent. fuming sulphuric acid in the water oven—and this without loss. In the case of pure indigotin, acids of greater strength than 20 per cent. fuming do cause decomposition when the duration of sulphonation is three-quarters of an hour at the temperature of the water oven.

Later experiments showed that temperatures above that of the water oven gave rise to considerable loss where fuming acid is used with pure indigotin (*v.* p. 741).

The following table shows some of the conditions under which a loss of indigotin may be expected on sulphonation:—

Sulphonation of crude Bengal indigos.

Mode of Sulphonation.	Indigotin crystallised from Nitrobenzene.		Sublimed Indigotin.	
	Permanganate used.	Percentage of Indigotin.	Permanganate used.	Percentage of Indigotin.
	c.c.	per cent.	c.c.	per cent.
12·5 per cent. fuming acid—				
½ hour at 97° C.	9·0 9·0 8·95 9·0	100 99·7	—	—
20 per cent. fuming acid—				
½ hour at 97° C.	9·0	100	9·0 9·0	100
½ hour at 110° C.	—	—	8·9 8·9	99
2 hours at 97° C.	—	—	8·85	98·3
30 per cent. fuming acid—				
10 minutes at 97° C.	8·90	99	—	—
20 minutes at 97° C.	8·90	99	—	—
37 per cent. fuming acid—				
½ hour at 97° C.	—	—	8·85	98·3

Sufficient pure indigotin was sulphonated by 100 per cent. sulphuric acid to just colour the liquid, the coloured liquid was then kept at a temperature between 90°—100° C., and a current of sulphur dioxide (dried by means of concentrated sulphuric acid) passed through the coloured liquid. No alteration or diminution of colour was observed after the gas had passed for one hour. Thus it was established that there was no fear of loss of indigotin by the evolution of sulphur dioxide in sulphonating, the gas being without action on the sulphindigotic acid in presence of concentrated sulphuric acid. Crude indigos are not so highly sulphonated as is pure indigotin when acted on by acid of the same strength for the same length of time and at the same temperature. Thus pure indigotin can be converted almost entirely into the tetrasulphonic acid by treatment with 20 per cent. fuming acid for half an hour in the water oven at 97° C.; whilst under similar conditions, a crude Bengal indigo would not be so completely converted into the tetrasulphonic acid on account of the impurities acting as a resistance or diluent to the sulphuric acid. Fuming sulphuric acid of some 5—10 per cent. greater strength is required to give the same degree of sulphonation as that attained by the pure indigotin. This lower degree of sulphonation

experienced in the case of crude indigos was revealed only during the course of the latter experiments (*v.* p. 76), which led to the adoption of the potassium tetrasulphonate method for the analysis of indigo.

Action of the di-, tri-, and tetra-sulphonic acids of indigotin on calcium carbonate.

These acids and their potassium salts having been prepared and the conditions established for sulphonation without loss, the way was now clear to determine whether Grossmann's process could be safely employed. Experiments showed, however, that the disulphonic acid, when treated at Grossmann's prescribed concentration (1 : 1000), yielded the blue calcium salt as a precipitate—but the solutions of tri- and tetra-sulphonic acids, when treated similarly, yielded no precipitates. Here then seemed possible an application of Grossmann's method for the purification of crude indigos after sulphonation, if the degree of sulphonation were carried as far as tri- or tetra-sulphonate. But again disappointment was experienced. On sulphonating crude cake indigos with fuming sulphuric acid of various strengths, the red (tetrasulphonate) product was obtained (see preceding page). But now a new difficulty arose, for, although no precipitation was now observed of the blue calcium disulphonate, on the addition of calcium carbonate, much less of the impurity was removed than when a lower degree of sulphonation was effected. So with regret it was determined that Grossmann's method could not be employed in the purification of crude indigos.

At this stage the author was driven to the following conclusions as to the applicability of the permanganate process to the estimation of indigotin :—

(1) It can only be used for the estimation of absolutely pure indigotin. Even in the case of synthetic indigos the impurities are estimated, wholly or in part, and the results thereby obtained are too high (*v.* p. 736).

(2) Its application to the analysis of synthetic and crude indigos is not possible, at this stage, for the several processes recommended for preliminary purification of the crude indigo fail in the following respects :—

(*a*) They fail to remove the impurities completely and too high results are obtained on titration.

(*b*) Whilst impurities are removed, indigotin is also thrown down, and the results of titration are too low.

SECTION II.—*Estimation of indigotin by means of titanium trichloride.*

This method had already been successfully employed by Knecht* for the analysis of other colouring matters, and its employment recommended in the case of indigo. In his paper of 1904, Knecht describes the method for the estimation of indigotin by titanium trichloride,† but he states that it is not possible to apply this new method to samples of natural and artificial indigo. In his paper of 1905 (*loc. cit.*), however, Knecht claims to have been able to apply the titanium method with success to the estimation of indigotin in crude indigo. He states that he is able to do so by making use of Grossmann's method of preliminary purification with calcium carbonate and titrating the filtrate.

As a result of experiments made, and of which an account follows, the author cannot agree that the method as published by Knecht is, as it stands, suitable for the quantitative estimation of indigotin in crude indigo. His suggestion of using titanium trichloride for this purpose was, however, a most valuable one.* For it is found that, with certain modifications, it can be employed with complete success, as an adjunct to the process shortly to be described.

In the first place, dealing with pure indigotin only (reserving the question of the possibility of accurate analysis by titanium trichloride of synthetical and crude plant indigos), it appeared from the simple details of the process given by Knecht, that the reaction was a quantitative one, free from complications. It was found, however, on investigation that the quantitative reduction of indigotin depended upon two main factors: (1) the relative concentrations of the solutions of indigotin and titanium trichloride; (2) the relation of tartaric acid to mineral acid present during the reduction. This is made clear by consideration of the following experiments :—

(1) *Influence of the relative concentrations of the solutions of indigotin and of titanium trichloride.*

The reaction is not a quantitative one under all conditions of concentration. If relatively weak solutions of indigotin are used, then the consumption of titanium trichloride is greater than that demanded by theory for the indigotin in solution. There is probably a reduction beyond the indigo-white stage, due to local excesses of titanium trichloride. Knecht employed an indigotin solution at a concentration of 1 grm. of indigotin in 500 c.c., and the titanium trichloride about twice as strong. These conditions, for the selection of which, however, no reason is given, only give accurate results when certain precautions are adopted. Thus, though not apparently recognised by Knecht, it is absolutely necessary in order to get constant and quantitative results, to adjust the proportions existing in the solution between the mineral acid and tartaric acid, and to add the titanium trichloride slowly, *i.e.*, drop by drop, and not in a constant stream, and to keep the flask constantly agitated during titration.

Having ascertained the conditions for accurate determination of indigotin at a concentration of 1 grm. per 500 c.c. of solution; the effect of different concentrations of indigotin was determined as follows :—

In order to make the test as consistent as possible, the indigotin solution titrated in each case was that containing for each dilution the same amount of indigotin in solution and the same amount of acid, *viz.* :—

(A) 25 c.c. = $\frac{1}{10}$ of 0·5 grm. indigotin + $\frac{1}{10}$ of 10 c.c. sulphuric acid.

(B) 50 c.c. = $\frac{1}{10}$ of 0·5 grm. of indigotin + $\frac{1}{10}$ of 10 c.c. sulphuric acid.

(C) 100 c.c. = $\frac{1}{5}$ of 0·25 grm. indigotin + $\frac{1}{2}$ of 5 c.c. sulphuric acid.

(D) 200 c.c. = $\frac{1}{5}$ of 0·25 grm indigotin + $\frac{1}{2}$ of 5 c.c. sulphuric acid.

So that every titration was a reduction of 0·05 grm. indigotin in presence of 1 c.c. of sulphuric acid (100 per cent.) and of 4 grms. of neutral sodium tartrate.†

On titration with titanium trichloride, the following results were obtained :—

---

* J. Soc. Dyers and Col., 1903, 86 and 189; 1904, 97 and 1905 192.

† Knecht points out that three chlorides are known :—$Ti Cl_2$, $Ti_2 Cl_6$, $Ti Cl_3$—and of these $Ti Cl_3$ is the true titanous chloride. $Ti Cl_3$ is, in this paper, written titanium trichloride.

* The author wishes to express here his indebtedness to Dr. Knecht, who was so kind as to allow Mr. S. H. Wood to visit his laboratory, and see his new method at work.

† Sodium tartrate (neutral) was substituted for the Rochelle salt of Knecht for reasons stated later (see next page). The relation of 4 grms. sodium tartrate to 1 c.c. acid was established by experiments (*ibid.*).

Concentration of Indigotin.	Burette readings.	Indigotin found per cent.	Actual per cent. of indigotin.
A.—25 c.c. of 1/500 + 4 grms. sodium tartrate	14·21, 14·25 (Mean 14·23)	98·9	100
B.—50 c.c. of 1/1000 + 4 grms. sodium tartrate	14·75, 14·75 (14·75)	103·6	100
C.—100 c.c. of 1/2000 + 4 grms. sodium tartrate	15·3, 14·9, 15·15, 14·7 (15·0)	105·4	100
D.—200 c.c of 1/4000 + 4 grms. sodium tartrate	16·8, 15·9 (16·1)	113·0	100

It will be seen from the results just given that the percentage of indigotin obtained increases as the solution becomes more dilute, and, moreover, that irregularity of the readings is apparent at greater dilutions. This irregularity is due to variations in the rate of addition of the titanium trichloride, which, as might be expected, has a greater effect on dilute than on concentrated solutions.

Even at a concentration of 1/1500 the rate of addition of the titanium trichloride solution is an important factor, as the following results show:—

Concentration.	Rate.	Burette readings.	Indicated per cent.	Actual per cent.
1/500	3 drops per sec.	14·2	99·74	100·00
	Continuous stream	14·6	102·6	
1/1000	3 drops per sec.	14·65	102·9	100·00
	Continuous stream	14·95	105·1	

It was thought at first that this increased consumption on dilution was due to the dissolved oxygen of the water, and, undoubtedly, that accounts for a small fraction of the error. Thus it was determined experimentally, that the dissolved oxygen in 300 c.c. of distilled water was only equivalent to 1 c.c. of the trichloride; so that (*v.* table above) 25 c.c. = 0·09 c.c.; this would cause a rise of only 0·5 per cent. when comparing 25 c.c. of a solution 1/500 concentration, with 50 c.c. of a concentration of 1/1000. That oxygen solution cannot account for the total error is shown by the fact that, if the titanium trichloride solution is correspondingly diluted, the results become quantitative again, though the burette readings are more liable to variation. Indigotin solution at a concentration of 1/5000, and titanium trichloride correspondingly diluted, gave, as a mean of three readings, 99·7 per cent.

It was finally determined that the most suitable concentration for the solution of indigotin was 1/500, the titanium solution being of about the same strength (N/60). This solution can then be used on pure indigotin and on crude indigos without introducing any error, for a crude indigo (of 50 per cent. indigotin content) would become, on making up for titration, 1/1000; and the reaction is quantitative when the titanium trichloride is not more than twice as strong as the indigotin solution, provided the titanium trichloride be run in slowly, and the flask constantly shaken.

(2) *The relations which must exist between tartaric and the mineral acids.*

As has been stated by Knecht (*loc. cit.*, 1904), if the reduction of indigotindisulphonic acid by titanium trichloride is effected in presence of mineral acid, the solution turns green, and no definite end point can be determined for the reaction. The addition of salts of tartaric acid he finds effectual in rendering the end point quite definite. Knecht used for this purpose Rochelle salt in excess; but, owing to the insolubility of the acid, potassium salt, which is produced, it was found preferable to use normal sodium tartrate. As will be shown, a serious error is introduced if excess of these salts be used.

The amount of salt necessary depends upon the amount of acid used in sulphonation, and upon the amount of hydrochloric acid used in making up the standard solution of titanium trichloride. Before the effect produced by the presence of an excess of the tartrate was known, several analyses of pure indigotin had given values of 103·6 per cent., 107·6 per cent., &c., because the same amount of salt had been used for pure indigotin sulphonated with different amounts of acid. This effect is shown by the following results:—

1 grm. of indigotin was sulphonated, with 20 c.c. of sulphuric acid (fuming 20 per cent. SO_3), for half an hour in the water oven, and subsequently made up to 500 c.c.

Volume of Indigotin solution.	Sodium tartrate.	Consumption of titanium trichloride.	Indicated per cent. of indigotin.	Actual per cent. of indigotin.
c.c.	grms.	c.c.		
25	3	No end point, merely green colour.		
25	4	13·95	100·2	100·0
25	5	13·5	101·4	100·0
25	6	13·65	102·3	100·0
25	7	13·85	102·8	100·0
25	8	13·85	104·0	100·0
25	9	13·9	104·5	100·0

So that every 25 c.c. of the indigotin solution used (containing 1 c.c. of acid) requires 4 grms. of normal sodium tartrate to give quantitative results, when titrated with a solution of titanium trichloride containing 1 c.c. of concentrated hydrochloric acid per 50 c.c. of solution.

The sodium value of the acid in the 25 c.c. of the solution of indigotin (used in the results shown in the table above) is, in terms of normal sodium tartrate, equal to 4·9 grms. of the salt. So that the requisite conditions for accurate titration, at this concentration, are not the addition of an amount of the neutral salt equivalent to the acid, but rather less of the tartrate. In using this process in general, it is therefore necessary, in order to obtain quantitative results, to ascertain the smallest amount of normal sodium tartrate necessary to give a sharp end-point, under the given conditions of sulphonation and of acidity of the solution of titanium trichloride, and then to adhere to these conditions rigorously. A further danger attends the use of sodium tartrate in large quantity, especially when added to a cold solution of indigotin. It tends to salt out the sulphonic acid, and, in this case, when the reduction appears to be complete, on close inspection blue masses of the salted-out sulphonic acid can be seen in the fluid, which have escaped titration and are now slowly dissolving. In this fashion low and irregular results are obtained.

To obviate the necessity for adding a large amount of tartrate, the amount of acid used for sulphonation should be reduced to a minimum—in the present experiments the standard relation adopted for indigotin to acid is 1 grm. of indigotin to 2 c.c. of acid—and the [illegible] (in the form of solution of 50 per cent. [illegible]

should be added to the hot solution of the sulphonic acid about to be titrated. When these two fundamental conditions had been determined for the quantitative interaction of indigotin with titanium trichloride, *e.g.*, the relative concentrations of the solutions of indigotin and titanium trichloride, and the relations which must exist between tartaric and mineral acid during reduction, excellent figures were obtained on sulphonation of pure indigotin, thus, in sequence, 99 per cent., 100·2 per cent., and 100·01 per cent. It may be stated here that all the foregoing results have been obtained on pure indigotin, prepared by sublimation, under diminished pressure, as stated at the commencement of this paper.

Several other organic salts were employed in place of normal sodium tartrate. The free acids of oxalates and acetates proved to be too strong to give the yellow end-point. Sodium citrate, however, was found to work as well as the tartrate. Citric and tartaric acids have the same conductivity, and are therefore of the same strength.

Use of titanium trichloride for the estimation of indigotin in crude indigos.

Titanium trichloride was tried by Knecht (J. Soc. Dyers and Col., 1904, **20**, 98) for the estimation of indigotin in natural and synthetical indigo. He states, "I was much disappointed to find that the impurities present marred the delicacy of the end-point to such an extent as to render the method quite unreliable, and further work on it was consequently abandoned." In a subsequent paper, however, (J. Soc. Dyers and Col., 1905, **21**, 292) he withdraws this opinion, stating that he has applied Grossmann's method of purification with calcium carbonate with success. "By adopting Grossmann's modification, all difficulties were removed, and even in the case of low grade indigos absolutely sharp end reactions were obtained." It is, however, to be noted here, that, in reality, Knecht does not seem to have followed Grossmann's modification. For Grossmann prescribes as being present in the flask of 500 c.c. capacity, after adding calcium carbonate and making up to the mark 500 c.c. = (0·1 grm. indigo + 2 c.c. acid + about 6 grms. pure calcium carbonate.) Whilst Knecht used 500 c.c. = (1·0 grm. indigo + 5 c.c. acid + 12 grms. "chalk"). Putting this point aside, the results obtained by the author, when Grossmann's method was tried in conjunction with potassium permanganate, indicated so complete a failure, that it seemed somewhat surprising that complete success could be claimed for the method when used in conjunction with titanium chloride. Experiments were now made both with pure indigotin and crude cake indigos under the conditions used by Knecht, and attributed by him in error to Grossmann. Of several experiments made, the following four suffice to show the inaccuracies of the method:—

	Buretto readings.	Indigotin per cent.
(1) *Pure Indigotin* (before treatment with calc. carb.)	14·35 / 14·40	99·65
(2) *Pure Indigotin* (after treatment with calc. carb.)	6·30 / 6·45	44·30
(3) *Crude Indigo* (before treatment with calc. carb.)	9·9 / 9·9	68·50
(4) *Crude Indigo* (after treatment with calc. carb.)	6·80 / 6·85	47·75

Here both pure indigotin and crude Bengal indigo are reduced in value by this process of "purification" to below 50 per cent.

The value 68·5 per cent. indigotin found for the crude indigo, before treatment with calcium carbonate, is of course high, as the impurities were all present and reacted with the titanium trichloride. The true value of this crude indigo was afterwards determined by the potassium tetrasulphonate method to be 61 per cent. indigotin.

So that the loss of indigotin involved in this process is—

Indigotin.

(1) Pure indigotin (100·0—44·3) = 55·7 per cent. loss.

(2) Crude cake (61·00—47·75) = 13·25 per cent. loss.

Several other experiments were made in order to remove the impurities with calcium carbonate, but in every case the values of both pure and crude indigos were reduced to between 40 and 50 per cent. indigotin.

An experiment was now made to see whether, if the titration were made as rapidly as possible after treatment with calcium carbonate, better results could be obtained. Grossmann does not state the time allowed for the precipitate to settle. Knecht prescribes 20—30 minutes as the time required for subsidence of the precipitate. In the present case, it was found possible to pipette off portions of the clarified solution 15 minutes after treatment with calcium carbonate.

So experiments were made at the intervals of time stated below, the solution being one of pure indigotin. 25 c.c. pipetted off after 15 minutes gave 47·7 per cent. indigotin, after 30 minutes gave 44·0 per cent. indigotin, after 45 minutes gave 44·0 per cent. indigotin, and after 60 minutes gave 44·0 per cent. indigotin.

Thus 15 minutes standing is sufficient for 50 per cent. of the indigotin to be carried down in the case of pure indigotin, and no further deposition was observed after standing 30 minutes to 1 hour. Thus the employment of Grossmann's process fails to give accurate results, whether potassium permanganate or titanium trichloride be used for estimation of the indigotin remaining in this filtrate. Further, Knecht's employment of calcium carbonate (in twice as great quantity) in an indigotin solution (10 times as strong) and in presence of acid (2·5 times as strong), as that prescribed by Grossmann—accentuated the short-comings of Grossmann's process, and, yielded a clear fluid for titration of 40—50 per cent. indigotin content, independent of the original value of the indigo or indigotin present.

It is now definitely claimed that it was possible, for the first time, to make accurate estimation of pure indigotin, if strict attention be paid to the experimental conditions prescribed in this paper—by both the permanganate method and that of titanium trichloride. The problem remaining was a difficult one. Was it possible to isolate quantitatively the indigotin of crude and synthetic indigos, in a state fit for estimation by one or both of these methods?

Conditions under which indigotin may be separated, with quantitative accuracy, as potassium tetrasulphonate, from the solutions of sulphonates of either pure indigotin or of crude indigo, by the use of potassium acetate.

In the investigation into the reason for the failure of Grossmann's method, it was made clear that this was due to the production of the disulphonic acid. If, however, sulphonation were carried further, *i.e.*, to the stage of tetrasulphonation, then within moderate limits of dilution, the addition of calcium carbonate was not followed by precipitation of the calcium salt of the tetrasulphonic acid. So it was thought possible that from such solution, after partial neutralisation with calcium carbonate the tetrasulphonate might be precipitated as its potassium salt, by the addition of potassium acetate. This salt had previously been used with success for a similar purpose by A. G. Perkin ("Notes on the purification of some Congo and Acid Red Colours," this J., 1903, **14**).

In the early experiments, success was occasionally obtained, the filtrate being almost colourless, but no standard conditions for success could be determined. The use of magnesium carbonate followed by potassium acetate gave, at intervals, successful results, but no general method could be prescribed. Finally, the use of potassium acetate alone was completely successful. The method of analysis developed on this basis is as follows for pure indigotin:—

The indigotin is dried at 110° C., and, after cooling in a desiccator, 1 grm. is weighed out into a small (6 oz.) spouted beaker. To the indigotin is added 2—3 grms. of purified sand, and 5 c.c. of fuming sulphuric acid (20 per cent. SO_3) is run in from a burette. After well stirring with a short glass rod, the beaker is covered with a watch glass and heated in the water-oven for half-an-hour, stirring being repeated at intervals. After cooling, the sulphonic acid is poured into a 500 c.c. flask containing some water and finally the beaker, stirring rod, and sand are repeatedly washed with water, when cold, the solution

is made up to the mark with water (when 500 c.c. = 1 grm. of indigotin + 5 c.c. fuming sulphuric acid.)

The following solutions are necessary :—

(a) *The precipitant*, a filtered solution of potassium acetate, 450 grms. per liter.

(b) *The isotonic*, prepared by adding 5 c.c. of glacial acetic acid to 200 c.c. of the precipitant, and then to 400 c.c. with water.

The analysis is carried out as follows :—100 c.c. of the indigotin solution (of 1/500 concentration) is delivered by a pipette into a fairly capacious conical spouted beaker. To this is now added from a burette (provided with a constant supply of the precipitant solution) 100 c.c. of the precipitant. Precipitation is observed when the solutions are well agitated in the conical beaker. The beaker and its contents are now well warmed until complete solution is attained. Cooling is now effected in a stream of running water, and when the contents of the flask are water-cold, the beaker is transferred to a vessel containing ice and water. Here the beaker is left for one hour, during which time the tetrasulphonate settles out as a fine-grained crystalline precipitate, which will filter well. Meanwhile the isotonic solution is placed in a spouted conical beaker and cooled by immersion in ice and water. The whole is filtered by suction through a Gooch crucible, the paper in which is set by a small quantity of the cooled isotonic solution. With good manipulation the operation is complete in a few minutes. In the case of pure indigotin a carefully performed analysis will yield a filtrate almost colourless. The very pale blue colour can be imitated by diluting a solution of tetrasulphonate of known indigotin value. In this way the indigotin strength of the filtrate, when the process is working well, is estimated at one part of indigotin in three millions of water, a loss which is entirely negligible. The Gooch crucible is now placed in a funnel which rests in the neck of a 200 c.c. flask. With the aid of hot water this is washed free from blue, and any precipitate which adheres to the walls of the conical beaker is dissolved and added to the main fluid, which on cooling is made up to the mark. Portions of this solution are used for the estimation of indigotin :—

(a) *By means of potassium permanganate.*—20 c.c. of the solution are transferred to a shallow porcelain dish and 80 c.c. of distilled water and 0·5 c.c. of pure concentrated sulphuric acid are added. This solution, which is not of a greater concentration than 1 in 5000, is titrated with the solution of potassium permanganate (1 in 1000), until the addition of a drop produces no longer a cloud in the pure yellow liquid. Indigotin (100 per cent.) would require under these circumstances 9·0 c.c. of permanganate, and percentages are calculated from this standard.

(b) *By means of titanium trichloride.*—In this case 25 c.c. of the solution of potassium tetrasulphonate is used for each estimation. This volume of solution is delivered into a conical Erlenmeyer flask of Jena glass of 300 c.c. capacity; to it is added 1·5 c.c. of a 20 per cent. solution of normal sodium tartrate, and the liquid is raised to boiling point, and then titrated whilst hot with a current of carbon dioxide passing through the flask.

Determination of the degree of sulphonation attained to in this process.—It was considered necessary to determine the nature of the precipitate obtained by the use of potassium acetate under the foregoing conditions. Accordingly 2 grms. of sublimed indigotin was sulphonated under the conditions stated, and made up to a liter. Of this 500 c.c. was precipitated with potassium acetate, collected on a filter, and washed with ice-cold "isotonic" solution. It was then redissolved in water and again precipitated (to remove any traces of potassium sulphate), filtered, and the precipitate washed with hot alcohol (to remove potassium acetate) and finally dried at 150° C. The freshly prepared precipitate was dark red, but on drying became pale blue. Analysis of the product gave [illegible] manganate), 35·5 per cent. and 35·6 per cent. Theory for tetrasulphonate, 35·69 per cent. indigotin.

Potassium: 0·2964 grm. salt yielded 0·1344 gr. potassium sulphate or 20·28 per cent. of potassium (theory, 21·25 per cent.).

Sulphur: 0·2068 grm. yielded 0·2508 grm. barium sulphate, i.e., 17·32 per cent. of sulphur (theory, 17·4 per cent.).

The salt was regarded as the tetrasulphonate from an inspection of these figures, showing the theoretical value of tri-, and tetrasulphonate.

——	Trisulphonate.	Tetrasulphonate.	Salt obtained.
Indigotin....	42·5	35·69	35·3
Potassium ..	19·9	21·25	20·3
Sulphur	15·57	17·4	17·32

In view of these results it was decided to call this process the "potassium tetrasulphonate method" for the analysis of indigotin.

One of the good points of this process is that it will reveal the presence of unsuspected impurities (present in the indigotin believed to be pure), or of degradation products produced by sulphonation with too strong acid, or by heating to too high a temperature. In both these cases, when the tetrasulphonate is precipitated, the impurities pass away in the filtrate, and as a result, the percentage of indigotin will be lower on resolution and estimation than if estimation be made direct on the original sulphonation product. Thus, in an experiment made to test whether pure sublimed indigotin would bear heating with 20 per cent. fuming acid in a glycerin bath at 110° C. for 15 minutes, the following figures were obtained :—After sulphonation and *before* precipitation with potassium acetate, 98·9 per cent. indigotin (permanganate), 98·2 per cent indigotin (titanium). After precipitation with potassium acetate and resolution, 97·2 per cent indigotin (permanganate), 97·35 per cent. indigotin (titanium); whence it was plain that destruction of indigotin had occurred to the extent of practically 3 per cent., and that this destruction was revealed by the aid of potassium acetate, whilst the results obtained before precipitation show that the destruction products were acted upon both by permanganate and titanium.

In the case of synthetic indigos, when sulphonation has been made under proper conditions, the sulphonate, before precipitation, will give results close to 100 per cent. with both the permanganate and titanium processes. But after precipitation, the indigotin value falls on titration to 91—92 per cent., the impurities having been removed in the filtrate. Evidence of this fact is obtained from the appearance of the filtrate after precipitation with potassium acetate. Thus, in the case of pure indigotin properly sulphonated, the filtrate is only very faintly blue or bluish-green. In the case just cited, where destruction occurred through faulty sulphonation, the filtrate showed the colour of a dilute solution of chrome alum. The filtrate obtained from synthetic indigos was also characteristic being green in the case of the Meister, Lucius und Brüning, and deep red in the case of the B.A.S.F. products.

It will thus readily be understood that great difficulty was experienced in the beginning in setting this process upon an exact quantitative basis, for it was necessary to be in possession of absolutely pure indigotin, to know the conditions under which it could be tetrasulphonated without loss, and to be able to recover and estimate this tetrasulphonate after precipitation and resolution. This degree of success was attained when the standard sublimed indigotin gave figures within a few decimal points of 100 per cent. before and after precipitation with potassium acetate. In one case only has the process failed to work, i.e., when the degree of sulphonation has been too low—thus, if the acid used has been too weak, or the temperature of sulphonation too low, or the time of sulphonation too short, then disulphonic acid is formed. This, on precipitation with potassium acetate, [illegible]

the acid of the water pump, the potassium disulphonate, which is non-crystalline, passes through the paper, appearing in the filter flask as a uniform blue fluid. Sodium acetate (anhydrous as supplied by Kahlbaum), has been tried as a substitute for the more expensive potassium salt, but it failed to produce the desired effect, the sodium tetrasulphonate being obtained in the non-crystalline state.

Application of the potassium tetrasulphonate method to the quantitative estimation of the indigotin of crude Bengal indigo.—Although the conditions for tetrasulphonation of pure indigotin without loss had been determined, a similar degree of knowledge was still to be attained in the case of crude indigos.

Thus, although pure indigotin is completely converted without loss into tetrasulphonate by heating with 20 per cent. fuming sulphuric acid for thirty minutes at 98° C., in the case of crude cake indigo it is found that the diluent effects, caused by the oxidation of some portion of the impurities, are so great on the fuming acid, that in this case an acid of some 5—10 per cent. greater strength in sulphuric anhydride is required to produce only the trasulphonate.

Air dry average factory "Mahai."—In order that the large number of experiments now to be made should be comparable one with the other, it was necessary to work always on the same material. There was fortunately available a large stock of air dry average factory "Mahai." This material was obtained in India by setting aside the superfluous pieces remaining after bottling specimens of the finished cake representing each day's output throughout the season of "Mahai" (manufacture), 1903—1904. The pieces were then well mixed together and reduced to fine powder, and finally passed through a very fine sieve. Thus an air dry powder was obtained, representing a fair average of the season's output. It was found by preliminary experiments that if the brown red impurities were separated from the crude cake indigo (*v.* next column), and if these were then subjected to sulphonation, the addition of potassium acetate, under the conditions of concentration adopted for analysis of pure indigotin, did not produce precipitation, the sulphonation products of the brown red impurities being, fortunately, more soluble. It was then decided that if fuming acid of 25—26 per cent. sulphuric anhydride were used to sulphonate the crude indigo, tetrasulphonate was obtained. Precipitation was effected with potassium acetate, and the process conducted as previously described (p. 741), but with two modifications. On filtration coming to an end, the tetrasulphonate precipitate was washed with the "isotonic" solution until the brown colour of the washings passed to colourless or faintly blue. The Gooch crucible and washed precipitate was then set aside and the main filtrate passed through a second Gooch crucible. In this way any traces of the sulphonate which escaped the first filtration were detained, washed, and finally dissolved and added to the main solution for titration. With these stated exceptions, the process was carried out as described in the case of pure indigotin. As a result of a large number of experiments the indigotin value of the "air dry average factory mahai" was found to lie between 57—59 per cent., whilst, after drying at 110° C., the values obtained were 60·3—61·9 per cent. indigotin (*v.* tables p. 743). These results were obtained by both the permanganate and titanium methods, good agreement being obtained, but the permanganate gave a result always about 1 per cent. higher than the titanium. An observation, which afforded great hope for the process as applied to crude indigos, was that the end point obtained on titration with permanganate was practically that of pure indigotin.

A large number of determinations have been made, in duplicate, on the "average factory mahai," the duplicates being in agreement and giving uniformly the figures just stated. Moreover, an extension of the enquiry to specimens of the daily output of the factory "mahai" (season 1903—1904) shows that, whilst duplicates are obtained agreeing well on one and the same sample, the examination of the product of other days' manufacture shows a different percentage of indigotin, but with the duplicates in good agreement (see tables, p. 743). Thus all the experimental evidence is in favour of the conclusions that the potassium tetrasulphonate method, when carried out as prescribed, gives the indigotin in the total quantity present in the cake, and that all the impurities pass away with the filtrate. But having regard to the fact that the establishment of an absolutely trustworthy process for the estimation of indigotin, both in pure indigotin, in synthetical and crude indigos, seemed a matter of such vital importance from the point of view both of the Indian indigo industry and of buyers and users of plant indigo, an attempt was made to remove all possible doubt on this matter.

Purification of Crude Indigo by Solvents.—Whilst in India, the author attempted to prepare pure indigotin by the action of solvents (acetic-sulphuric acid followed by methyl acohol); in this way residues were obtained from a crude cake indigo, which, weighed as being pure indigotin, gave in duplicate 70·34 per cent. and 69·34 per cent. as the indigotin content of the crude Bengal cake (dry at 110° C.). But a determination of the nitrogen value showed the real percentage indigotin to be 63·69 per cent. (Chem. Soc. Journ. Trans., 1905, 87, 982.) The present experiments showed that, using the potassium tetrasulphonate method, the indigotin value of average crude factory mahai (dry at 110° C.) was 60—62 per cent. So it appeared advisable to attempt to remove the several impurities of crude indigo by solvents, with a view to leaving a residue of pure indigotin, and thus finally testing the accuracy of the tetrasulphonate method.

The main impurities associated with crude cake indigos are the so-called indigo gluten (Berzelius, Jahresber., 7, 256), indigo brown (Berzelius loc. cit.), together with varying proportions of mineral matter and what may be termed leaf débris. The indigo yellow or Kampheral of Perkin (Chem. Soc. Proc., 1905, 20, 172) was absent in the material dealt with, and need not at present be discussed. The indigo gluten and some of the mineral matter are readily removed, as is well known, by means of hot dilute hydrochloric acid (1 : 4). But, as regards the indigo brown, which is undoubtedly a mixture of substances, no satisfactory solvent has previously been suggested for its complete removal. After numerous experiments, however, it was found that pyridine effected this object, for whereas by this solvent indigotin is almost inappreciably attacked in the cold, the indigo brown is very readily dissolved.* In carrying out this process finely powdered crude indigo was digested with boiling pyridine (Kahlbaum II.) for a few minutes and the mixture allowed to cool and set aside overnight. On filtration a deep brownish red liquid was obtained and the residue on the filter was washed with pyridine several times, until the filtrate no longer possessed this tint. The final washings possessed a very pale blue colour, but this, it was ascertained, represented an almost negligible quantity of indigotin. Proceeding in this manner, the following results were obtained, the analyses being made in duplicate :—

	(I.)	(II.)
Loss of weight after treatment with hydrochloric acid (1 : 4)	21·58 per cent.	21·21 per cent.
Loss of weight after treating with pyridine the residue from HCl.	17·49 per cent.	18·03 per cent.

These residues, after pyridine extraction, were dried at 120° until no smell of pyridine could be detected, and then sulphonated. Titration was then effected with permanganate, before and after treatment with potassium acetate, with the following results :—

(*a*) Before treatment with potassium acetate, 95·0 per cent. and 95·0 per cent. indigotin.
(*b*) After treatment with potassium acetate, 91·1 per cent. and 90·5—91·9 per cent.

The fact that the purified indigo only contained 91 per cent. of indigotin then received attention.

* The author, in conjunction with Mr. A. G. Perkin, is at present investigating this brown substance, and desires to reserve to himself at present this method for its isolation.

The end reaction on titration showed that the residue was free from coloured impurities. Estimation of the ash showed the value to be 1·85 per cent. Now if this mineral matter were present as oxalate, as seems quite possible, it might account for nearly 4 per cent. of the impurity. Nitrogen estimations showed that there was still some nitrogenous impurity remaining which had escaped extraction, thus two determinations, gave 10·63 and 10·65 per cent. = indigotin 99·46 and 99·65 per cent.

It was suggested that the high nitrogen value might be accounted for by the presence of leaf débris. This would naturally be resistent to solvents, would contain nitrogen, and on sulphonation, would almost certainly give rise to products upon which permanganate would act, but which would be removed in the filtrate after treatment with potassium acetate, and hence the observed lower values in the figures set forth.

An experiment was carried out to determine whether leaf débris could be detected in the residue after extraction with acid and pyridine. A weighed portion of the residue was placed in an extraction thimble and subjected, in a Soxhlets' apparatus, to prolonged extraction with pyridine. When the pyridine washings came through colourless, the thimble was heated in an air oven until no smell of pyridine could be detected. On again weighing the thimble and residue, the weight of the residue was determined to amount to 3·55 per cent. of the material subjected to experiment. The residue proved, on ignition, to contain mineral matter to the extent of 1·27 per cent., leaving more than 2 per cent. as leaf débris.

This experiment is not regarded as final, and an attempt is being made to make quite clear the chemical nature of the material which resists solution after treatment with acid and prolonged extraction with pyridine.

Before leaving this portion of the subject, it is to be noted that if the figures, obtained as above on treatment of the average crude factory mahai (air dry) with acid and pyridine, are calculated back to show the indigotin content of the air dry material, we have the following close relation between the results obtained by the extraction process and the potassium tetrasulphonate method (60—62 per cent.). Two calculations gave 61·57 and 61·17 per cent. respectively.

So that at present, although it is not proved possible to be able, by the action of solvents to remove from crude cake indigo all impurities save indigotin; and thus by direct experiment to prove the absolute accuracy of the tetrasulphonate method—all the evidence is in favour of its being an accurate method. As a final proof of the accuracy of the potassium tetrasulphonate process, pure indigotin was mixed with known weights of the brown material (previously removed from crude Bengal cake by the action of pyridine and dried at 140° C.); on sulphonating these mixtures, and separating the indigotin as potassium tetrasulphonate, the indigotin percentage obtained on titration was precisely that of the mixture made.

In conclusion, it is confidently hoped that, as a result of the experiments previously described, the way is now open, for the first time, for the quantitative examination of natural indigo in the finished cake, and at all stages of its manufacture; and that it may be possible to apply the potassium tetrasulphonate method in India to the detection of the defects of the present method of manufacture, and also to the many methods in which assistance can be now rendered to enable natural indigo to hold its own against the competition of the synthetic product.

In the report on the work done at Dalsingh Serai for the Government of Bengal (*loc. cit.*, Section II., p. 7.), the author expressed the opinion that the "efficiency" of the present method of manufacture was very low. This prediction is fulfilled, as is clearly shown, by inspection of the results obtained on applying the potassium tetrasulphonate process to the products of the Pembercandah Factory Mahai, Season 1903—1904.

Tables showing the results of analyses, employing the potassium tetrasulphonate method, of the Pembercandah Factory "Mahai" Season, 1903—1904:—

Average	5·0	61·9	60·5	0·1834

From these results, it will be seen that if the percentage of indigotin contained in the whole plant (ordinary Indian varieties) be taken, as seems reasonable, at 0·6 per cent. Then from consideration of the weights of plant steeped and the indigotin recovered in the finished cake—the highest efficiency attained does not reach 50 per cent. of the total indigotin obtainable, whilst the average efficiency of the "Mahai" is 25 per cent., falling thence to 12·6 per cent. (cake No. 2). The attention of the Government of India will be called to this wasteful method of manufacture, with a view to the long-needed improvements being introduced to India without delay.

The author's thanks are due to the university authorities for the excellent facilities so freely placed at his disposal; also to Prof. A. G. Green for his unvarying kindness in this direction. In connection with the work itself, he is greatly indebted to his assistants Messrs. I. Q. Orchardson and S. H. Wood, who have been unremitting in their efforts to bring the work to a successful conclusion, and to whom much of the experimental work has naturally fallen.

He has finally to express his deep sense of gratitude to Mr. A. G. Perkin, F.R.S., with whom he has been daily associated, for the many and most valuable suggestions which have borne fruit in this investigation.

Discussion.

Prof. A. G. Green congratulated Mr. Bloxam on the results which he had obtained and said that they were a good example of what could be achieved by skilled analytical work. It was 50 years since Mohr had first put forward the permanganate titration method and had clearly set out its faults. It had thus taken 50 years to perfect the process. Mr. Bloxam was an optimist, and believed in the future of plant indigo. Recent news from India showed that there was every probability of an increase of yield of 50 per cent. in the production of most factories, and a simultaneous rise in quality of the product from second to first-class. The introduction of the Java-Natal plant had been the chief factor in bringing about this improvement.

Mr. T. Fairley asked if colorimetric tests would be of any value in supporting Mr. Bloxam's work. He suggested the use of Lovibond's tintometer. Possibly leaf debris might be separated from powdered crude indigo cake by suspension of the latter in solutions of various specific gravities and subsequent spinning in a centrifugal machine.

Mr. S. H. Davies said he presumed that the accurate determination of indigotin would be applied not only in the factory but to agricultural problems involved in the cultivation of indigo, and to the selection of the best varieties of the plant.

Mr. A. G. Perkin said that having frequently seen Mr. Bloxam's process working, he had no doubt that it was effective and simple, and might be worked by the average student with success. Much that was unreliable had been written on indigo analysis, and it was difficult to understand Wangerin and Vorländer's paper. The confidence placed in their results had greatly hindered Mr. Bloxam's work. Again, it did not seem to be known that powdered glass, recommended by some writers as useful during sulphonation, contained iron, and yielded with the acid a ferrous salt, which, of course, reacted with the potassium permanganate in the titration. The salting out process, again, did not entirely remove this defect. Purification of the glass by digestion with acid had been resorted to by Mr. Bloxam, but was tedious, and only removed the iron from the surface of the glass, so that during the stirring some iron again entered solution.

Mr. W. P. Bloxam, in reply, said he thought the new method would meet the present needs. What he still desired to discover, however, was the function of the impurities of plant indigo, and to ascertain what body or bodies was or were responsible for the scouring experienced by dyers in using plant indigo. In applying the potassium tetrasulphono-indigotate process to the analysis of synthetical indigos some curious results were obtained. None of them had been found to contain more than 92 per cent. of indigotin, and it was found possible to recognise the product by the colour of the filtrate—thus that from Meister, Lucius und Brüning gave a green, whilst the B.A.S.F. product gave a red filtrate. The method of analysis was so delicate that an instance might be cited in proof. The process was originally established on pure indigotin obtained by sublimation as standard. It was later found necessary to prepare more pure indigotin for use as standard. Three separate sublimation products were obtained and examined separately with solvents, &c., and pronounced to be pure. The three products were then mixed together and the value determined by the potassium tetrasulphono-indigotate process. The results showed the indigotin value to be slightly below 100 per cent., and on making a more stringent examination of the sublimation product with solvents, &c., the results of the analysis were confirmed, showing that one at least of the three sublimation products contained a small quantity of impurity which had at first escaped detection.

English Patents.

Separators; Impts. in centrifugal liquid ——. J. P. Johansson, Enkaping, Sweden. Eng. Pat. 18,444, Sept. 12, 1905.

The invention relates to liners for centrifugal machines which are formed of a number of vertical plates arranged round an axis, and bent in a direction inclined to the radii of the liner. The cover and bottom piece of the drum and the top and bottom of the liner are convex, so as to correspond to one another in order that the plates of the liner may be supported along the whole length of their upper and lower edges by the top and bottom of the drum, thus obviating the use of distance pieces between the plates. The distance between adjacent plates is gradually decreased from the axis to the periphery of the liner, and the spaces are quite free from obstructions of any kind, so that the liner can be easily cleaned.

—W. H. C.

Separating machines; Impts. in ——. W. S. Ayres, Hazleton, Pa., U.S.A. Eng. Pat. 19,914, Oct. 3, 1905.

The materials to be separated are caused to pass over a number of overlapping, rotating, flat or slightly conical discs. A forward movement among the particles to be separated is caused by inclining the series of discs from the inlet to the outlet, and a lateral movement is caused by the rotation of the discs. The discs are rotated "synchronously," and the lighter particles travel forward by gravity, being directed by a guide-bar, passing across the whole series of discs, from the feed to the outlet about. The heavier particles are carried but laterally by the rotating discs, and are finally dropped off the edges

of the latter into another trough. A modification in which only one disc is used, is described, and reference for further details is made to Eng. Pat. 19,913 of 1905 (this J., 1906, 981).—W. H. C.

Liquids; Apparatus for the continuous supply of two —— to a vessel. W. P. Thompson, London. From A. Schmitz, Aachen, Germany. Eng. Pat. 19,378, Sept. 25, 1905.

See Fr. Pat. 358,007 of 1905; this J., 1906, 168.—T. F. B.

Straining or filtering water or other liquids; Apparatus for ——. E. Gobbi, Asnières, France. Eng. Pat. 7616, March 29, 1906. Under Int. Conv., Dec. 23, 1905.

The filter is formed of a number of rings or discs piled one upon the other, and held tightly pressed together. A central tube passes through the pile. The liquid to be filtered passes through the interstices between the discs to the central tube. The filter can be cleaned by allowing some of the filtered water to flow backwards between the discs, which are loosened for the purpose, and are provided with springs between each pair of adjacent discs to keep them apart when the pressure holding them together is removed.—W. H. C.

United States Patents.

Ammonia-still [for ice-machines]. B. Thoens, New York. U.S. Pat. 818,858, April 24, 1906.

The patent relates to absorption ice and refrigeration machines, and consists in improvements whereby practically anhydrous ammonia gas can be produced for delivery to the absorption apparatus. The vapours from the ammonia generator, before entering the absorption apparatus, pass through a "rectifier-coil" cooled by water, and then to a separator, whereby practically the whole of the water vapour present is condensed. The condensed water from the coil and from the separator is returned to the ammonia generator.—A. S.

Ammonia [in refrigerating machinery]; Regenerating and purifying ——. L. Werlin, Elsmere, Del. U.S. Pat. 824,459, June 26, 1906.

Of the compressed ammonia, a portion is condensed, and of this portion a part is expanded to obtain the cooling effect, and the residual portion is evaporated "by the heat of condensation of the remaining [second] portion of the warm compressed gas." The vapours thus produced are purified by the action of the cold exhaust gas from the expansion device, whereby the less volatile impurities are condensed to a liquid free from ammonia; then the exhaust gas and the purified ammonia vapours are mixed and re-compressed.—E. S.

Separating liquids from solids; Apparatus for ——. W. H. Lomas, Doornfontein, Transvaal. U.S. Pat. 825,331, July 10, 1906.

See Eng. Pat. 149 of 1905; this J., 1906, 184.—T. F. B.

French Patents.

Volatile solvents diffused as vapours in the air of factories; Process for the recovery of ——. J. Douge. Fr. Pat. 362,611, Jan. 22, 1906.

The large volumes of air or of air and aqueous vapour with which the vapours of the volatile solvents are usually mixed, render the usual methods of recovery, such as condensation, refrigeration, absorption by liquids, or compression and subsequent expansion, of little practical value. The object of this invention is to remove the greater portion of the diluting air or air and aqueous vapour before proceeding to any of the above-mentioned methods of recovery. To attain this object, the mixture of air and vapour is aspirated from the localities in which it is produced, by a centrifugal aspirator separator, which, owing to the difference in the specific gravities of the air and vapour, is able to separate it into two parts, one of which consists chiefly of air and aqueous vapour, containing only a small proportion of the vapours to be recovered, and which is either returned to the building or discharged direct into the atmosphere. The other part, consisting of a mixture much richer in valuable vapours, is sent through a second and if necessary through a succession of similar machines. Finally, when the desired concentration has been attained, the vapours are recovered by passing this rich mixture through any of the ordinary types of apparatus to carry out the methods mentioned above.—W. H. C.

Centrifugal apparatus; Impts. in ——. L. Fuchs. Fr. Pat. 362,673, Jan. 24, 1906.

The claim is for improvements in that type of centrifugal machines in which the contents are discharged through the bottom, which is lowered for that purpose. This in the improved method is lowered not by an arrangement of levers, as in the ordinary machines, but by hydraulic or pneumatic pressure applied from below to a chamber surrounding the axis of the machine.—W. H. C.

Dryer for loose materials. B. Schilde. Fr. Pat. 362,853, Jan. 30, 1906.

The loose materials are placed on trays, the sides of which are grooved on the outside to form a kind of rack. The trays are piled one upon the other in a drying chamber, and are slowly lowered one by one on to guide-rails at the bottom, by means of toothed wheels, which engage with the racks on the sides of the trays. When the bottom tray is lowered upon the guide-rails, it is moved away horizontally, emptied, recharged, and replaced on the top of the pile, and another tray lowered.—W. H. C.

Carbon; Solubility of —— in calcium carbide. H. M. Kahn. VII., page 758.

Tar; Use of —— in making water-gas. G. H. Waring. J. Gas Lighting, 1906, 95, 35—36.

Oil tar has been used successfully as a generator fuel since 1898 in the works of the Omaha Gas Company, U.S.A. The tar is first freed from water by passage through two separators, and subsidence, and is then stored in the top of the first condenser, whereby it is

brought to about 130° F. The hot tar is sprayed into the generator along with steam, the spraying device being that shown in the accompanying illustration. Tar is admitted with the steam only on a down run, which is about every third one. To keep the 1-in. inlet pipe clear, the steam is turned on before, and is also cut off after the

tar supply. The gas maker admits the tar to the generator after turning on the oil in the carburetter, and shuts it off before turning off the oil. No unusual fouling of the plant occurs, the amount of smoke produced is unobjectionable, and the tar made is not affected in any way. Experience has shown that not more than 0·5 gall. of tar per 1000 cb. ft. of carburetted water-gas made can be used efficiently with oven coke, or 0·4 gall. when using gas coke, unless the down runs are more frequent than once in three. On the average, 1 gall. of water-free tar is equal to 8 lb. of oven coke or 10 lb. of gas coke. At the Philadelphia Gas Works the experience of several years shows that 1 gall. of tar is equal to 7 lb. of anthracite, and that not more than 0·25 gall. per 1000 cb. ft. of gas can be used efficiently along with anthracite. The tar has also an enriching effect upon the gas. There is a marked increase in the proportions of hydrogen and methane in the gas, and the calorific value is increased by about 11 per cent. Of the tar produced in the water-gas plant, from one-third to two-thirds can be used as fuel in the above manner, and it is suggested that if the process were adopted generally, the market value of the disposable balance of the tar would increase.—H. B.

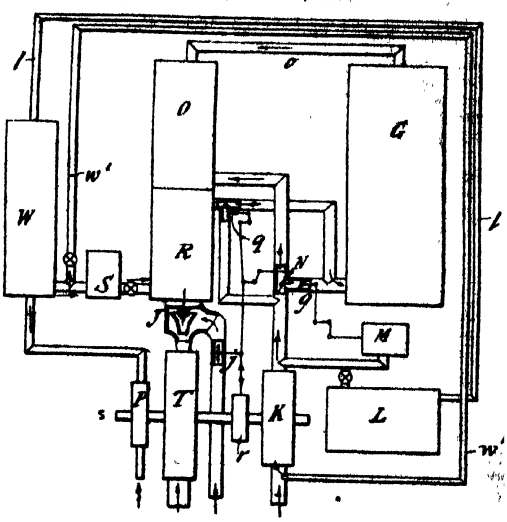
Gas-engines built in Great Britain; Notes on ——, and upon gas-cleaning. T. Westgarth. Iron and Steel Inst., July, 1906. [Advance proof.]

SCHEDULES are given showing the number and particulars of gas-engines of 500 h.p. or more which have been built or are being built by British makers, together with some notes on the various systems of gas cleaning.

Gas-engines; Application of large —— in the German iron and steel industries. K. Reinhardt. X., page 761.

Hefner, Harcourt, and Carcel lamps. Photometric investigations by the Physical-Technical Imperial Institute at Charlottenburg on the relation of the intensity of light of the Hefner lamp to the 10*-candle pentane lamp and the carcel lamp.* E. Liebenthal. J. Gas Lighting, 1906, **95**, 102—103.

INVESTIGATIONS at the Charlottenburg Institute have shown that the light of the 10-candle pentane lamp (as prescribed by the London Gas Referees), at an atmospheric pressure of 760 mm. and a humidity of 8·8 litres of aqueous vapour per cubic metre of dry air, is equal to 11 Hefner units under the same conditions. With a humidity of 10 litres (which is regarded at the National Physical Laboratory as the average humidity applicable to London), the value is 10·9 Hefner units (taking the Hefner unit at 8·8 litres). Harcourt's statement, that the light of the lamp does not vary if the flame fluctuates by as much as 6 mm. above or below the prescribed height, is found to be nearly correct if the flame be higher, but not if it be lower; if the tip of the flame plays about the lower edge of the inspection window, the light is about 3 per cent. lower than the normal. Using all precautions, the variations in the light of one and the same lamp, with the same pentane, and under the same meteorological conditions, were found to be upwards of 1 per cent. in the course of several hours. The light of the lamp decreased 0·55 per cent. for an increase of 1 litre in the amount of aqueous vapour per cubic metre of air—a decrease which is the same as that of the Hefner and 1-candle pentane lamps. The light increased 0·6 per cent. for an increase of 10 mm. in the barometric pressure, whereas the increase in the light of the Hefner and 1-candle pentane lamps respectively was only 0·1 and 0·4 per cent. The standard of light used for the above comparisons was a constant incandescent electric lamp. Earlier comparisons with the English candle gave a value of 1·14 Hefner units, and from these and the above results it would appear that the illuminating power of the 10-candle pentane lamp is about 4 per cent. lower than 10 English candles.



The carcel lamp was found to have an illuminating power (on the basis of the like atmospheric humidity) equal to 10·8 Hefner units, on the average; but the light fluctuated considerably, and the figures from which the mean value, 10·8, was deduced, vary among themselves by upwards of 10 per cent.—H. B.

ENGLISH PATENTS.

Fuel; Method of converting the chemical energy of —— into the kinetic energy of a moving fluid, and apparatus for use in connection therewith. A. Vogt, Tulse Hill, Surrey. Eng. Pat. 3607, Feb. 21, 1905.

A TURBINE, T, a water-pump, P, an air-compressor, K, and a governor, r, are all coupled together on the shaft, s. The compressor, K, delivers compressed air into the air-reservoir, L, the generator, G, and the combustion chamber, O, the distribution being controlled by the regulator, N, operated by the governor, r. In the generator, G, gas is produced by the action of the compressed air on the fuel, and is conducted by the pipe, o, to the combustion chamber, O, where it meets with a further supply of air, and is burnt. The water-pump, P, delivers water into the reservoir, W, which is connected to the compressed-air store, L, by the pipe l. From W, the water is forced by the compressed air partly along the pipe, w^1, to the intake of the compressor, K, and partly through the float valve, S, into the regenerator, R, where it is converted into steam, and passes on to the generator, G, or to the compressed-air main, the distribution being regulated by the valve, q. From the combustion chamber, O, the gases issue through an expansion nozzle of the "Laval" type to the regenerator, R, where the heat is utilised in converting the water into steam; the partly cooled gas then passes through the injector, J, into the turbine, T, where its velocity is utilised. By means of the valve, j, connected to the governor, r, a regulated amount of air is drawn by the injector from the atmosphere to further cool the gas issuing from the regenerator, R. The quantity of air entering the generator, G, is further controlled by the damper, g, connected to the diaphragm regulator, M, on the compressed-air main. The heat generated by the compressor is partly absorbed by the water entering by the pipe, w^1, and the generator and combustion chamber are very thoroughly protected against loss of heat by radiation.—W. H. C.

Gas fires and the like; Manufacture of refractory bodies for use in ——, for heating purposes. M. Delage, Paris. Eng. Pat. 12,466, June 16, 1905. Under Int. Conv., Oct. 26, 1904.

Cerium oxide is mixed, in the proportion of 10 to 50 per cent., with other refractory substances, such as aluminium silicate, and the mixture is moulded into the

desired forms. The refractory bodies so prepared emit practically no light, but are said to radiate a large quantity of heat.—H. B.

Burners for liquid fuel; Impts. in ——. W. Dieckmann, Edmonton; F. C. Ormrod, Walthamstow; J. A. Curle, Woodford; and S. F. Stockard, Muswell Hill. Eng. Pat. 13,013, June 23, 1905.

THE burner consists of three concentric nozzles, the intermediate one being for the supply of liquid fuel, whilst the outermost and innermost are for the supply of air or steam. The mouthpiece of one or more of the nozzles is shaped to have an orifice of a non-circular (*e.g.*, an oval) cross-section. The innermost nozzle is rotatable, so as to constitute a needle valve for regulating the fuel supply, and when its mouthpiece is of non-circular cross-section, it is provided with a connection whereby the nozzle may be rotated without rotating the mouthpiece.—H. B.

Gas producers; Impts. in ——. H. Foster and O. T. Greener, Newport, Mon. Eng. Pat. 14,575, July 14, 1905.

THE producer is provided with an iron hearth or combustion chamber in the form of a hollow, inverted, truncated cone, the hearth being of sufficient depth to contain the whole of the fuel, and the slope of the side being such that the clinker will be forced downwards by the weight of the superincumbent fuel into the water-sealed ash-pit at the bottom. The lower part of the sides of the hearth is provided with grids for the admission of air and steam. A casing with vertical sides surrounds the hearth. The air and steam blasts enter the top of the space formed between the hearth and the casing, and, on flowing round the hearth on their way to the grids, take up heat from it, and keep it at a moderate temperature.—H. B.

Gas producers; Impts. in suction ——. J. J. Bowmor, Newcastle-on-Tyne. Eng. Pat. 22,382, Nov. 2, 1905.

A SMALL boiler, round which the hot producer gases are drawn, is attached to one side of the producer, and is connected to a chamber in front of the fire-grate through a loaded valve. It is also provided with an escape valve loaded to a lower pressure than the latter valve, so that the steam generated passes off into the air unless drawn into the producer by the suction of the engine. An air pipe, which passes through the boiler flue, and supplies heated air to the producer, is likewise connected to the chamber in front of the fire-grate, the steam pipe and air pipe being controlled by a common loaded valve, so that steam and air in proper proportions only enter the chamber at each suction stroke.—H. B.

Gas generators; Impts. relating to ——. H. Goehtz, Hildesheim, Germany. Eng. Pat. 1331, Jan. 17, 1906. Under Int. Conv., Nov. 30, 1905.

THE generator is provided with an annular grate, arranged concentrically at the bottom of the combustion chamber, the grate consisting either of a ring of sheet iron of $\wedge$-shaped cross-section, or of a series of semicircular bars forming an annulus of $\cap$-shaped cross-section. The blast of steam and air is delivered into the annular grate through pipes, and either passes out beneath the lower edge of the annulus, or issues through the intervals between the bars. A roof-shaped deflecting plate, standing in the ash-pit beneath the grate, deflects the ashes descending through it to points convenient of access.—H. B.

Carburetting apparatus [for air-gas]; Impts. in ——. F. Hugershoff, Leipsic, Germany. Eng. Pat. 2440, Jan. 31, 1906.

THE carburetter proper, consisting of a zig-zag pipe of rectangular cross-section, is arranged within a casing filled with water, which serves as an attemperating liquid. Air is delivered by means of a meter drum at the lower end of the carburetter, and in passing upwards constitutes a downwardly flowing stream of the carburetting liquid, which is admitted in regulated doses at the top end of the carburetter. Within the casing is arranged a number of vertical pipes, through which atmospheric air may circulate, to assist in maintaining a uniform temperature, and a rotary stirring wheel, driven by the meter drum, to keep the attemperating water in motion. The carburetted air issues through a branch pipe at the upper end of the carburetter, and may be led off to a separate gas-holder, or into a bell, inverted over the casing, and adapted to serve as a gas-holder.—H. B.

Gases produced in the destructive distillation of coal or other carbonaceous material; Purification of ——, *and apparatus therefor.* G. Wilton, London. Eng. Pat. 2907, Feb. 6, 1906.

THE crude gas from, say, the hydraulic main is led directly, without the intervention of the usual condensing plant, through a scrubber in which it is caused to bubble through cooled gas liquor, preferably containing light tars in admixture. The liquor is caused to circulate from the scrubber through a cooling tower, so as to re-enter the scrubber always in a cold condition. The cooling and scrubbing thus effected may be preceded by treating the gas in the hydraulic main with cooled gas liquor, for the removal of heavy tars and naphthalene.—H. B.

Incandescent mantles; Treatment of the woven tubes or of the yarns used in the manufacture of ——. A. I. van Vriesland, Scheveningen, Holland. Eng. Pat. 24,680, Nov. 29, 1905.

SEE Fr. Pat. 359,945 of 1905; this J., 1906, 467.—T. F. B.

Arc lamp electrodes; Impts. in ——. The British Thomson-Houston Co., Ltd., London. From Allgem. Elektricitäts.-Ges., Berlin. Eng. Pat. 20,330, Oct. 9, 1905.

IN the manufacture of electrodes consisting essentially of metals, such as iron or manganese, or of metallic oxides, or of titanium carbide, finely powdered silicon carbide is mixed with the material of the electrode. The silicon carbide, it is stated, does not fuse when the arc is formed, and thus steadies the arc.—H. B.

UNITED STATES PATENTS.

Coke oven. W. Klönne, Rath, Germany. U.S. Pat. 825,221, July 3, 1906.

Smoke; Apparatus for purifying ——. W. Cline, Assignor to J. F. Brimmer and W. Fuhrman, Lancaster, Pa. U.S. Pat. 824,469, June 26, 1906.

THE smoke passing from the flue to the chimney is caused to traverse a chamber interposed between them. A liquid is sprayed into this chamber near the inlet end, and in the same direction in which the smoke is passing. The spray washes the smoke, and falls to the bottom of the chamber, and is then conducted by a pipe to a series of settling tanks, where the impurities are deposited, and from which the purified liquid is pumped back to the sprayer for use over again.—W. H. C.

FRENCH PATENTS.

Fuel; Manufacture of artificial ——. J. M. A. Stillesen. Fr. Pat. 362,901, Jan. 4, 1906.

SEE U.S. Pat. 809,998 of 1906; this J., 1906, 169.—T. F. B.

Motive fluid for internal combustion motors; Preparation of a ——. P. Winand. Fr. Pat. 363,021, Feb. 6, 1906. Under Int. Conv., Feb. 8, 1905.

SEE Eng. Pat. 3006 of 1906; this J., 1906, 582.—T. F. B.

Furnaces for vertical retorts. E. Derval. Fr. Pat. 362,501, Jan. 18, 1906.

THE retort setting is characterised by the arrangement of the producer and recuperators upon the same level as the retort chamber, the hot products of combustion from the latter being led into the recuperators at the top, and forcing down them in a direction opposite to that of the inflowing air. The retort chamber is divided by

three series of horizontal partitions, which cause the burning gases flowing round the retorts to change their direction four times before reaching the outlet; the quantity of heated air admitted with the producer gas is insufficient for its complete combustion, and a supplementary supply of air is admitted at the third change of direction, to ensure, by the renewed combustion, the adequate heating of the lowest sections of the retorts. Methods of building up the retorts, and devices for closing them, and for introducing steam, are described.—H. B.

Gas-producer. A. J. J. Adam. Fr. Pat. 362,312, Jan. 10, 1906.

The cover of the producer, which carries a charging hopper and fuel distributor, eccentrically disposed, is adapted to be rotated continuously in a horizontal plane, so that the fuel may be discharged over the entire fuel bed. The fuel distributor, which is arranged within the lower part of the hopper, consists of a conical body, rotating on a horizontal axis, and formed with a longitudinal V-shaped trough which alternately fills with, and discharges, the fuel. The cover is in the form of a shallow tray, and is kept filled with water to prevent over-heating. The fuel in the producer rests upon a plate, which is suspended from chains wound upon pulleys arranged round the lower part of the producer; the blast-pipe extends centrally upwards through the plate, which, by the gradual rotation of the pulleys, is caused to descend slowly as the fuel is consumed, thus keeping the top level of the fuel constant. When the plate has reached the base of the producer, bars are inserted through the furnace walls at a point above the cinders, so as to form a temporary grate, whereupon the cinders are raked out, and the plate wound up again to its highest level, descending again *de novo*.—H. B.

[*Locomobile*] *Gas-producer.* H. Hurlebusch. Fr. Pat. 362,425, Jan. 15, 1906.

The locomobile gas-producer consists of a small producer of any suitable kind, attached to a casing having the general aspect of the boiler of a locomobile, the top of the casing serving as the foundation of a gas engine. Within the casing is arranged the apparatus for purifying and cooling the gas on its way from the producer to the engine; it consists of a series of compartments and channels, provided with water-spray and beds of moist coke and sawdust. The entire apparatus is mounted on wheels.—H. B.

Gases; Apparatus for the analysis of ——. Monopol Betriebskontroll-Apparate, K. Steinbock. Second Addition, dated Dec. 4, 1905, to Fr. Pat. 359,352, Nov. 2, 1905. XXIII., page 778.

Filaments for incandescent lamps; Process for the formation of ——. Zirkon-Glühlampenwerk. Dr. Hollefreund and Co. Fr. Pat. 362,847, Jan. 30, 1906.

The filaments, either loosely or in bundles, are placed along with a piece of any suitable metal, alloy, mixture of metals, or carbon, in a tube of metal or porcelain, which is then sealed up hermetically. As complete a vacuum as possible is next produced in the tube, which is afterwards heated to such a temperature that the metal, &c., inside is volatilised, and deposited as a fine, adherent film upon the filaments. After cooling, the vessel is opened, and the filaments taken out to undergo any other desired treatment, or to be used as they are.—W. H. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 687.)

Hydrocarbons; Oxidation of —— *by ozone at low temperatures.* J. Drugman. Chem. Soc. Proc., 1906, 22, 163—164.

The mode of action of ozone on a saturated and an unsaturated hydrocarbon is very different. Ozone acts, at the ordinary temperature, very slowly on saturated hydrocarbons such as methane and ethane. The process is one of gradual hydroxylation. In the case of ethane, ethyl alcohol is the first product formed.

The reaction in the case of an unsaturated hydrocarbon such as ethylene is instantaneous, even at temperatures far below 0°C. A very explosive addition compound is first formed, which decomposes extremely readily, giving oxidation products containing only one carbon atom. The carbon chain is broken at the double bond. Comparison with the results of Harries' work makes it appear probable that the addition product is an ozonide, but the decomposition of this is more complex than that usually obtained with a liquid or solid ozonide. The following equations probably represent the process:—

(1) $C_2H_4 + O_3 = C_2H_4O_3 = \begin{cases} (a)\ CH_2O + HCO_2H \\ (b)\ CH_2O + CO + H_2O \end{cases}$

(2) $C_2H_4O_3 + H_2O = 2CH_2O + H_2O_2$.

ENGLISH PATENT.

Tar oils, phenols, and similar products; Emulsions of ——. W. Spalteholz, Amsterdam. Eng. Pat. 13,151, June 26, 1905.

See Fr. Pat. 355,342 of 1905; this J., 1905, 1166.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 687.)

α-Naphthol and benzophenone chloride; Condensation products of ——. A. G. Shrimpton. Chem. News, 1906, 94, 13—14.

Diphenyldi-α-naphtholmethane, $(C_6H_5)_2C(C_{10}H_6.OH)_2$, was formed by the condensation of α-naphthol with benzophenone chloride, according to the equation:—

$(C_6H_5)_2CCl_2 + 2C_{10}H_7OH = (C_6H_5)_2C(C_{10}H_6OH)_2 + 2HCl$.

It forms microscopic crystals melting at 208·2°—209·2° C., is soluble in benzene, carbon bisulphide, ether, acetone, and chloroform, less soluble in alcohol and petroleum spirit, and dissolves in alkalis, giving a madder-brown solution, which shows a blue fluorescence. By modifying the method adopted for the preparation of the above compound, a second condensation product was obtained, consisting of fine yellow microscopic crystals melting at 180·5 to 181° C., and possessing good dyeing properties.—D. B.

Trinitrobenzene derivatives with cyclic amines; Contribution to the knowledge of ——. E. O. Sommerhof. Z. Farben.-Ind., 1906, 5, 270—271.

The author cannot admit V. Georgievic's contention (this J., 1906, 530) that picric acid must exist in two modifications because it dyes wool different shades from a cold and from a boiling bath. In the cold, he states, the picric acid is merely fixed on the fibre in the form of a solid solution. On heating, a "loose" chemical combination is formed between the picric acid and the wool fibre, which is of a darker colour than the dyestuff itself. Similarly, picric acid and also trinitrobenzoic acid form compounds of different colour with aromatic amines. Thus on mixing equimolecular methyl alcoholic solutions of trinitrobenzoic acid and pseudo-cumidine in the cold, a colourless salt is obtained; on warming an isomeric coloured substance, a "loose" molecular addition product is formed.—H. L.

Phenylacetic acid ketone dyestuffs. Trihydroxydeoxybenzoin and derivatives thereof. E. Noelting and V. Kadiera. Ber., 1905, 38, 2056—2060.

The authors have condensed pyrogallol with phenylacetic acid, and obtained phenylgallacetophenone (trihydroxydeoxybenzoin) m.pt. 141°—142°, a homologue of trihydroxybenzophenone (Alizarin Yellow A) the condensation product of pyrogallol and benzoic acid. By treating the new substance with hydroxylamine the ketoxime, m.pt. 166° C., and with sodium nitrite or amyl nitrite the isonitrosoketone, m.pt. 144° C., respectively were

obtained. The di-isonitroso derivative, m.pt. 168° C., was prepared by treating the oxime with sodium nitrite, and this substance was converted into the corresponding diketone, trihydroxybenzil, m.pt. 143° C., by acids, the isonitroso groups being eliminated. These five new substances are mordant dyestuffs similar to gallacetophenone [Alizarin Yellow C) and trihydroxybenzophenone. Their dyeing properties are given in the following table :—

Dyestuff.	Cotton mordanted with :		Wool mordanted with chrome.
	Alumina.	Iron.	
Ketone	olive-orange	brownish-black	olive
Diketone	olive-orange	brownish-black	olive
Isonitrosoketone	olive-orange	brownish-black	olive
Oxime	a little greener and duller		greenish-olive
Di-oxime	the same as the monoxime		greenish-olive
Gallacetophenone	greenish-yellow	greyish-black	greenish-olive
Trihydroxybenzophenone	orange	brownish-black	reddish-olive

—H. L.

Triphenylmethane derivatives ; o-Hydroxylated ——. E. Noelting and P. Gerlinger. Ber., 1906, **39**, 2053—2056.

4¹.4².4³-Hexamethyltriamino-2³-hydroxytriphenylmethane $(CH_3)_2N.C_6H_3(OH).CH[C_6H_4.N(CH_3)_2]_2$ is prepared by condensing Michler's carbinol with dimethyl-*m*-aminophenol by means of concentrated hydrochloric acid and a little alcohol. Recrystallised from alcohol it forms fine white needles turning reddish on exposure to the air, and melting at 172°—174° C. with decomposition. It is easily soluble in organic solvents. Oxidation to a blue dyestuff is very incomplete owing probably to the presence of an *o*-hydroxyl group. On the other hand the acetyl compound obtained by treating the leuco body with hot acetic anhydride can be smoothly oxidised with lead peroxide, and yields a dyestuff which dyes the fibre blue with a violet tone.

4¹.4².4³-*Hexamethyltriamino-2¹.2³-dihydroxytriphenylmethane* $(CH_3)_2N.C_6H_3(OH).CH[C_6H_3(OH)N(CH_3)_2][C_6H_4.N(CH_3)_2]$ is prepared by condensing *p*-dimethylaminobenzaldehyde with 2 mols. of dimethyl-*m*-aminophenol. It crystallises from alcohol in white needles, melting at 175° C. with elimination of water, which gradually turn pinkish when exposed to the air. It is readily soluble in dilute aqueous alkalis, and in organic solvents. Oxidation with lead peroxide and glacial acetic acid produces only a poor yield of a violet-blue dyestuff. The di-acetyl compound of the leuco body is, however, readily oxidised to a dyestuff which produces fairly strong violet-blue shades. When the leuco body is dissolved in concentrated sulphuric acid and heated for six hours on the water-bath, a molecule of water is split off, and a very readily oxidisable dark bluish-red substance

$$O<\begin{matrix}C_6H_3.N(CH_3)_2\\C_6H_3.N(CH_3)_2\end{matrix}>CH.C_6H_4.N(CH_3)_2$$

is obtained. By heating this leuco product to 150° C. with concentrated sulphuric acid, it is oxidised to the corresponding dyestuff, which represents the dimethyl-*p*-amino derivative of Rosamine. It produces very bluish-red—almost violet—shades. The introduction of the same group into the Malachite Green molecule, it is pointed out, produces Crystal Violet. Here the change is much less marked. The introduction of one or two acetoxy groups in the *o*-position in the Crystal Violet molecule has, further, much more effect on the shade than the introduction of a pyrone oxygen atom.—H. L.

Malachite Green ; Influence of substitution in the benzene ring on the shade of ——. E. Noelting and P. Gerlinger. Ber., 1906, **39**, 2041—2053.

The influence of substitution in the unsubstituted benzene ring of Malachite Green,

$$C_6H_5.CH<\begin{matrix}C_6H_4.N(CH_3)_2Cl\\C_6H_4.N(CH_3)_2,\end{matrix}$$

as far as hitherto determined, is as follows. A nitro-group in the *p*-position makes the shade yellower (see E. and O. Fischer, Ber., 1879, 800 and 802, and O. Fischer, Ber., 1881, 2524 ; 1882, 632 ; and 1884, 1839), in the *o*-position much bluer, and in the *m*-position is without any effect on the shade. Methyl in the *p*-position produces a yellowish-green (see Hanzlik and Bianchi, Ber., 1899, 1287) ; chlorine in the *o*-position a greenish-blue known as Setocyanine (see Geigy, Ger. Pat. 94,129), in the *p*-position a yellowish-green according to the authors and not a bluish-green as described by Käswurm (see Ber., 1886, 742). A sulphonic acid group in the *o*-position produces a well-known blue fast to alkalis (see Geigy, Ger. Pats. 80,892 and 87,176). An *o*-carboxyl prevents the formation of a dyestuff ; the presence of an esterified *o*-carboxyl group makes the shade much bluer (see Haller and Guyot, Compt. rend., **119**, 206). Neither *o*-, *m*-, nor *p*-hydroxyl has much influence on the shade (see O. Fischer, Ber., 1881, 2522). The authors have filled in the gaps in the above series of substituted Malachite Greens by preparing the *o*- and *m*-methyl, *m*- and *p*-chloro, and *m*-sulpho derivatives and also the *o*-, *m*-, and *p*-methoxyl derivatives of Malachite Green substituted in all cases in the benzal nucleus. They find that, as already observed in the nitro bodies, substitution in the *o*-position makes the shade bluer, in the *p*-position yellower, and in the *m*-position is without influence.

—H. L.

Phenolphthaleïn and quinolphthaleïn ; Constitution of the salts of ——. A. G. Green and P. E. King. Ber., 1906, **39**, 2365—2371.

The view of Green and Perkin (this J., 1904, 319) that the coloured salts of phenol- and quinol-phthaleïns possess a quinonoid structure has been adversely criticised by Meyer and Spengler (Ber., 1905, **38**, 1318), who adhere to Meyer's conception of these salts as lactone derivatives, and accept Baeyer's theory of a carbonium valence (this J., 1905, 320) as an explanation of their colour. Meyer and Spengler in their communication specially emphasised the fact that notwithstanding numerous attempts, no coloured, quinonoid carboxylic esters of phenol- and quinol-phthaleïns have been prepared, similar to those obtained by Nietzki from Fluorescein. The authors have succeeded in preparing such coloured esters, which is further confirmation of their view that the coloured salts of phenol- and quinol-phthaleïns possess a similar quinonoid structure to that of the salts of fluorescein.

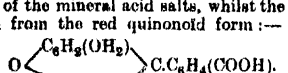
Methyl ester of phenolphthaleïn.—Phenolphthaleïn was dissolved in boiling methyl alcohol, the solution saturated hot with zinc chloride, and a current of hydrogen chloride led through. After standing overnight, the dark red solution was poured into ice-cold, faintly acidulated water. The voluminous scarlet precipitate which separated was rapidly filtered off, washed with ice-cold water, and dried between filter-paper. The analytical results and properties of the product confirmed the view that it was the quinonoid methyl ester of phenolphthaleïn :

$$\begin{matrix}(COOCH_3)C_6H_4\\(HO)C_6H_4\end{matrix}>C:C_6H_4:O.$$

The ester is very unstable, being completely decolorised by contact with water for 12 hours, or with alcohol for a few minutes.

Methyl ester of quinolphthaleïn.—A solution of the phthaleïn in five parts of methyl alcohol was subjected to the action of a current of hydrogen chloride for half an hour, and the solution allowed to stand overnight, when a dark red, crystalline precipitate separated. This was filtered off, and washed with alcoholic ether. It consisted of the chloride of the quinonoid methyl ester of quinolphthaleïn :—

$$(COOCH_3).C<\begin{matrix}C_6H_3(OH)\\C_6H_3(OH)\end{matrix}>O.Cl.$$



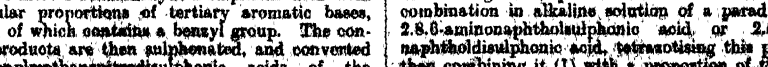
The chloride is stable when dry, but is slowly hydrolysed on boiling with water. It has not been found possible to isolate the free ester, owing to the ease with which it undergoes hydrolysis.—A. S.

Phthalein series; Salts formed with mineral acids in the ——. G. Heller. Z. Farben-Ind., 1906, 5, 265—269.

The author shows that Gallein, $C_{20}H_{12}O_7$, the phthalein of pyrogallol, is capable of forming stable well-crystallised salts with mineral acids, and this property may be utilised for the preparation of pure Gallein hydrate. Thus 1 part of commercial anhydrous Gallein is gently warmed with 10 parts of 96 per cent. alcohol and 1 part of concentrated hydrochloric acid. The nearly clear solution obtained is filtered, and the phthalein is precipitated with water. This product is then dissolved at the ordinary temperature in 4 parts of alcohol (or acetone), with the addition of 2 parts of alcoholic hydrochloric acid. Gallein alcoholate hydrochloride soon begins to crystallise out; it is filtered off and carefully added to concentrated sulphuric acid, in which it dissolves with an intense red colour. This solution is filtered through glass-wool, and on precipitation with water, pure Gallein hydrate, $C_{20}H_{12}O_7,H_2O$, is obtained.

Gallein alcoholate hydrochloride, $C_{20}H_{12}O_7,HCl,C_2H_5OH$ (prepared as described above), crystallises in fine brown needles. By dissolving Gallein in acetone or methyl alcohol, and adding concentrated hydrochloric acid to the solution, Gallein acetonate hydrochloride, $C_{20}H_{12}O_7,HCl$, C_3H_6O (blue-black needles), and Gallein methylalcoholate hydrochloride respectively are obtained. Gallein sulphate, $C_{20}H_{12}O_7,H_2SO_4$, and Gallein hydrobromide, $C_{20}H_{12}O_7,HBr$, are similarly prepared; both crystallise free from solvent. All these salts are decomposed by water. The author has further prepared the hydrochloride and sulphate of Gallein ethyl ester, the hydrochlorides of hydroxyquinolphthalein alcoholate, acetonate, and methyl alcoholate and hydroxyquinolphthalein sulphate, which are all crystallised substances decomposed by water. These salts are of theoretical interest in view of recent publications of Werner on partial valencies (Annalen, **332**, 296) and of Baeyer (Ber., **38**, 570) on the basic character of the carbon atom and on "carbonium" isomerism.

Pure Gallein hydrate is a stable reddish-brown crystalline substance, which may be dried at 100° without decomposition. It loses a molecule of water at 180° C., and begins to sinter at 240° C. When very finely ground and shaken with a small quantity of acetone or alcohol, it dissolves very readily with an intense violet coloration. On diluting or warming this solution, or allowing it to stand for some time, the coloration disappears, and a faintly red-tinted solution is obtained. This solution contains the Gallein in a different form, which must be the lactone form, the faint red coloration being due to the presence of small quantities of a red quinonoid form, which is isomeric with the violet modification. This red modification may be isolated as a dark red crystalline powder by adding a small quantity of chloroform to the acetone solution. By adding chloroform in gradually increasing quantity, practically all the dissolved dyestuff may be precipitated in this form. The violet modification is the basis of the mineral acid salts, whilst the alkali salts are derived from the red quinonoid form:—

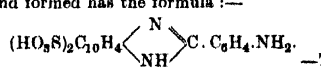


On acidifying alkaline solutions with acetic acid the red form is obtained, while with mineral acids the violet is precipitated owing to the secondary action of the mineral acid. There are thus in all four forms of Gallein, of which three have been isolated as definite compounds.—H. L.

English Patents.

Dyestuffs; Manufacture of green acid mordant ——. O. Imray, London. From Farbw. vorm. Meister, Lucius, und Brüning, Hoechst a/Main, Germany. Eng. Pat. 17,382, Aug. 28, 1905.

New green acid mordant dyestuffs are prepared by condensing 5-nitro-1-benzaldehyde-2-sulphonic acid with two molecular proportions of tertiary aromatic bases, one or both of which contains a benzyl group. The condensation products are then sulphonated, and converted into triphenylmethanenitrodisulphonic acids of the following general formula:—



In this formula R^1, R^2, and R^3 represent a methyl, ethyl, or benzyl group. These nitrodisulphonic acids, which are in the form of leuco-compounds, are reduced to aminodisulphonic acids, diazotised, and combined with salicylic or cresotinic acid. The azo compound is converted into the finished dyestuff by oxidation with lead peroxide. Example, (*a*) 5-nitro-2-sulpho-1-benzaldehyde is prepared by boiling a solution of 185 kilos. of 5-nitro-2-chloro-1-benzaldehyde in 1000 litres of alcohol, with a solution of 140 kilos. of sodium sulphite in 500 litres of water, for 24 hours in a reflux apparatus. The solution is filtered and may then be directly used. (*b*) 422 kilos. of ethylbenzylaniline are introduced into this solution of 5-nitro-2-sulpho-1-benzaldehyde and then 100 kilos. of 96 per cent. sulphuric acid are added. The mixture is boiled for 24 hours, and the reaction product is precipitated with water, filtered, dried, and sulphonated on the water-bath by means of four parts of concentrated sulphuric acid. The sulphonated product is precipitated with water, filtered, and reduced in the usual way. (*c*) The *m*-amino-diethyldibenzyldiaminotriphenylmethanedisulphonic acid so prepared is diazotised, and combined in alkaline solution with salicylic acid, and the product is oxidised with lead peroxide. The dyestuff is obtained as a dark green powder readily soluble in water, which is said to dye wool, treated with chromium salts previously or subsequently to dyeing, in strong green shades fast to washing and padding.—H. L.

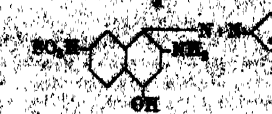
Colour bases; Products soluble in water, fats, and oils from the salts which higher fatty acids and acids of the oleic series form with ——. Meister, Lucius, und Brüning. Eng. Pat. 10,079, April 30, 1906. XIII*A*., page 768.

Phenyl-1.2-naphthimidazole or homologues or derivatives thereof; Manufacture of amidosulphonic acids of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 20,780, Oct. 13, 1905.

The *o*-amino-azo-compounds of the naphthalene series, obtained by combining diazotised *p*-phenylenediamine or acetyl-*p*-phenylenediamine with certain naphthylaminosulphonic acids (*e.g.*, 2.5.7-naphthylaminedisulphonic acid), are combined with a nitrobenzaldehyde or aminobenzaldehyde to form a triazine derivative; on reduction, *e.g.*, with iron and acetic acid, the nitro group or groups are reduced, and also the *p*-phenylenediamine residue is eliminated, whereby there is formed a phenylnaphthimidazolesulphonic acid derivative; thus, from the naphthylaminesulphonic acid referred to above, the compound formed has the formula:—

—T. F. B.

Colouring matter [Thio-indigo Red]; Manufacture of organic compounds containing sulphur, and of red —— *therefrom.* G. W. Johnson, London. From Kalle und Co., Akt.-Ges., Biebrich on Rhine, Germany. Eng. Pat. 22,736, Nov. 6, 1905.



See Fr. Pat. 359,398 of 1905; this J., 1906, 424.—T. F. B.

Colouring matter [Thio-indigo Red]; Manufacture of red sulphur-containing ——. G. W. Johnson, London. From Kalle und Co., Akt.-Ges., Biebrich on Rhine, Germany. Eng. Pat. 23,316, Nov. 13, 1905.

See Fr. Pat. 359,399 of 1905; this J., 1906, 424.—T. F. B.

Azo colouring matter [Dyestuff]; Manufacture of ——. H. W. Lake, London. From the Chem. Fabr. Griesheim-Elektron, Frankfort-on-Maine, Germany. Eng. Pat. 6189, March 14, 1906.

New polyazo dyestuffs are claimed, which dye cotton directly in black shades stated to be of remarkable fastness to washing. The process consists in first preparing a combination in alkaline solution of a paradiamine with 2.8.6-aminonaphtholsulphonic acid, or 2.8.3.6-aminonaphtholdisulphonic acid, tetrazotising this product, and then combining it (1) with a proportion of the following aminomonoazo dyestuff,

and (2) with a meta-diamine of the benzene series. In place of the above aminoazo dyestuff the corresponding monoazo dyestuffs, containing a nitro or acetylamino group in place of the amino group, may be employed. In this case the nitro group is reduced, or the acetyl group is split off by hydrolysis, after combination is completed.

Example I.—7·5 parts of acetyl-*p*-phenylenediamine are diazotised and combined in alkaline solution with 11·95 parts of 2.8.6-aminonaphtholsulphonic acid. The product is hydrolysed with caustic soda to split off the acetyl group, tetrazotised, and then combined in alkaline solution with 24·1 parts of the above monoazo dyestuff. When the formation of this intermediate product is complete, 5·4 parts of *m*-phenylenediamine are added. After 12 hours the solution is warmed to 70° C., and the dyestuff is precipitated with salt. It dyes cotton in deep black shades.

Example II.—12·2 parts of dianisidine are tetrazotised, and combined in alkaline solution with 17·05 parts of 2.8.3.6-aminonaphtholdisulphonic acid. The intermediate product is then further diazotised, and allowed to run into an alkaline solution of the monoazo dyestuff obtained by combining acetyl-*p*-phenylenediamine-*o*-sulphonic acid with 11·95 parts of 2.5.7-aminonaphtholsulphonic acid in acid solution. When combination is complete the new body is further combined with 6·5 parts of *m*-toluylenediamine. The acetyl group is then split by boiling with aqueous caustic soda. The dyestuff dyes cotton in black shades.

The new products are said to equalise very well owing to the presence of the para amino group, which also increases the dyeing power, and deepens the shade.

—H. L.

Sulphinic acids of the aromatic series; Manufacture of ——. C. Dreyfus and The Clayton Aniline Co., Ltd., Manchester. Eng. Pat. 7288, March 26, 1906.

Sulphinic acids of the aromatic series may be produced by diazotising primary aromatic amines, and treating the diazo solutions with finely-divided copper or other copper compounds in the presence of sulphurous acid. Nitrogen is evolved, and the original amino group is replaced by the sulphinic group, SO_2H. The patentees claim the use of cuprous sulphide, or a mixture of cuprous sulphide with finely-divided sulphur or other substances in place of the finely-divided copper or copper salts hitherto employed. The requisite mixture of cuprous sulphide and sulphur may be prepared by continued heating of an aqueous solution of a cupric salt and sodium thiosulphate, or by boiling with water the precipitate of sodium cuprous thiosulphate (obtained by mixing hot solutions of copper sulphate and sodium thiosulphate) until decomposition takes place. The material is best used moist and in a finely-divided condition, and during the evolution of nitrogen the temperature should not be allowed to exceed 5° C. Examples are given, describing the preparation of *o*-toluenesulphinic acid from *o*-toluidine, benzenecarboxylic-*o*-sulphinic acid, $C_6H_4(COOH)(SO_2H)$, from anthranilic acid; naphthalene-1-sulphonic-4-sulphinic acid from naphthionic acid; and a sulphinic acid of the following constitution:—

$$[N(CH_3)_2.C_6H_4]_2CH.C_6H_2(CH_3)(SO_2H)$$
$$[SO_2H:CH_3:CH=1:2:4]$$

from *p*-tetramethyldiaminodiphenyl-*p*-amino-*o*-tolylmethane.—H. L.

1.2-Diazonaphtholsulphonic acids; Manufacture of salts of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabr., Ludwigshafen-on-Rhine, Germany. Eng. Pat. 10,525, May 2, 1906.

The sulphonic acids of 1.2-aminonaphthol may it is claimed, be diazotised by treating the free acids with nitrites in the presence of common salt or other alkali or alkaline-earth salt. Example. A solution of 7 parts of sodium nitrite in 30 parts of water are allowed to flow rapidly, with good stirring, into a mixture of 24 parts of 1.2-aminonaphthol-4-sulphonic acid with a solution of 15 parts of common salt in 200 parts of water. Diazotisation is complete after about three-quarters of an hour, and a clear brownish-yellow solution is obtained. The diazo oxide of the sulphonic acid may be obtained, it is stated, by acidifying this solution with hydrochloric acid. (See also Eng. Pat. 25,034 of 1905; this J., 1906, 393.)

—H. L.

Colouring matters of the anthracene series [Anthracene dyestuffs]; Manufacture of ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabr., Ludwigshafen, Germany. Eng. Pat. 10,505, May 4, 1906.

The dyestuffs derived from 2.2′-dimethyl-1.1′-dianthraquinonyl or derivatives or homologues thereof (see Fr. Pat. 357,239 of 1905; this J., 1906, 68) are converted into new dyestuffs by chlorinating agents. The new products are similar in appearance to the unchlorinated dyestuffs, but produce redder shades. They may be converted into cherry-red vats, which produce bluish-red shades on cotton, changed into bright orange-red by washing.—H. L.

Anthracene series; Manufacture of compounds of the ——, *and of colouring matter [Sulphide dyestuffs] therefrom.* J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 13,057, June 6, 1906.

Dianthraquinonylamine, obtained as described in Fr. Pat. 357,138 of 1905 (this J., 1906, 66), is nitrated by treatment with nitric acid in presence of nitrobenzene; a nitro compound is formed, which appears to be dinitrodianthraquinonylamine; by melting this substance with alkali sulphide, a dyestuff is obtained which dyes cotton blue shades from an alkaline hydrosulphite vat.—T. F. B.

Dyestuffs; Manufacture of red vat dyeing ——. O. Imray, London. From Soc. of Chem. Ind., Basle. Eng. Pat. 10,405, May 3, 1906.

Red vat dyeing dyestuffs similar to thioindigo are said to be produced by heating a mixture of salicylthioacetic acid with isatin and an aromatic nitrohydrocarbon or acetic anhydride at a high temperature. The new dyestuffs crystallise in the form of brilliant yellowish-red to brownish-red needles, and dye cotton in yellowish-red shades much yellower than those produced by thioindigo.

—H. L.

Dyestuffs; Manufacture of red, violet, and blue vat dyeing ——. O. Imray, London. From Soc. of Chem. Ind., Basle. Eng. Pat. 11,760, May 19, 1906.

Red, violet, and blue vat dyeing dyestuffs are produced by heating a mixture of salicylthioacetic acid or thioindoxyl with the arylides of isatin, its homologues, or substitution products, in the presence of acetic anhydride or an aromatic nitrohydrocarbon or alcohol.

Example I.—Three parts of salicylthioacetic acid, 2·5 parts of *α*-isatinanilide, and 25—30 parts of acetic anhydride are boiled under a reflux condenser for 2—3 hours. After a short time the solution acquires a bluish-violet colour, and the dyestuff begins to separate. On cooling and filtering, it is obtained as lustrous bluish-violet felted needles, which dye cotton in violet-blue shades from an alkaline hydrosulphite vat.

Example II.—Two parts of thioindoxyl, 3 parts of *α*-isatinanilide, and 30 parts of acetic anhydride are boiled under a reflux condenser for 2—3 hours. The dyestuff which separates in violet-red crystals dyes cotton from an alkaline hydrosulphite vat in reddish-violet shades, stated to be of great fastness.

Two further examples are given. It is stated that the violet to blue dyestuffs obtained from *α*-isatinarylides contain the arylamine group in the molecule, whilst *β*-isatinarylides yield red dyestuffs probably identical with those prepared from isatin, the arylamine group being eliminated. (See preceding abstract.)—H. L.

FRENCH PATENTS.

1.2-Naphthylene-urea-hydroxysulphonic acids, and azo dyestuffs therefrom; Manufacture of ——. L. Cassella und Co. Fr. Pat. 361,335, April 6, 1905.

1.2-NAPHTHYLENE-UREA-HYDROXYSULPHONIC acids are produced by dissolving diaminonaphthalenehydroxysulphonic acids, *e.g.*, 1.2-diamino-5-hydroxynaphthalene-7-sulphonic acid, in water, and passing in a current of phosgene in the presence of sodium acetate. 1.2-Diamino-5-hydroxynaphthalene-7-sulphonic acid is prepared by reducing a monoazo dyestuff obtained by combining a diazo compound with 2.5-aminonaphthol-7-sulphonic acid in acid solution. The new urea separates out as sodium salt in brilliant colourless crystals of the following constitution :—

$$SO_3Na \atop OH > C_{10}H_4 < \overset{NH}{NH} > CO$$

It is readily soluble in hot, but sparingly soluble in cold water. The free acid is obtained as a colourless crystalline powder by the addition of mineral acids to solutions of the sodium salt, and is a not readily oxidisable substance, the alkaline solutions of which show an intense violet-blue fluorescence. It may be readily combined in alkaline solution with diazo compounds, and yields, it is stated, valuable monoazo- and polyazo dyestuffs distinguished by brilliant shade, fastness to acids, and strong affinity for cotton. The monoazo dyestuffs prepared from 1.2-naphthylene-urea-hydroxysulphonic acids and diazotised bases of the benzene series such as aniline and its homologues, acetyl-*p*-phenylenediamine, aminophenol ether, sulphanilic acid, &c., produce scarlet shades on cotton; *α*-naphthylamine and its sulphonic acids, aminoazobenzene and its sulphonic acids violet-red to violet shades, benzidine, tolidine, and dianisidine reddish-blue to blue shades. The dyestuffs prepared from *o*-aminophenol and its derivatives are said to yield wool colours, of excellent shade and fastness after chroming. One example is given, in which the combination of diazotised *o*-toluidine with 1.2-naphthylene-urea-5-hydroxy-7-sulphonic acid is described.—H. L.

Anthraquinone derivatives [*Arylaminoanthraquinones*]; *Production of* ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 362,140, Jan. 3, 1906. Under Int. Conv., Jan. 9, 1905.

ARYLAMINOANTHRAQUINONES or their derivatives are produced by heating aminoanthraquinones with halogen derivatives of aromatic compounds, or their substitution derivatives, in the presence of copper or copper compounds, substances, such as chalk, sodium acetate, magnesia, &c., being, with advantage, also added to the mixtures employed, to combine with the halogen acids formed in the reactions. *p*-Nitrophenyl-*α*-aminoanthraquinone is, for example, obtained by acting at 200° C. with *p*-chloronitrobenzene (100 kilos.) on *α*-aminoanthraquinone (10 kilos.), in the presence of copper chloride (0·5 kilo.) and anhydrous sodium acetate (3 kilos.). A compound which is probably symmetrical 1.4-dichlorodiphenyldiaminoanthraquinone, is similarly prepared by heating under pressure at 200°—210° C., a mixture of *p*-dichlorobenzene, 1.4-diaminoanthraquinone, copper chloride, and sodium acetate. 1-Naphthylamino-4-hydroxyanthraquinone, again, is formed from a mixture of *α*-chloronaphthalene, the sodium salt of 1-amino-4-hydroxyanthraquinone, copper carbonate, and anhydrous sodium acetate. Numerous other examples of the application of the method are given in the original specification.—E. B.

1.2-Dichlorobenzenesulphonic acid; Separation of the isomeric acids formed in the nitration of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 362,574, Jan. 20, 1906.

1.2-DICHLOROBENZENE-4-SULPHONIC acid on nitration in the usual way is known to yield 1.2-dichloro-3-nitrobenzene-4-sulphonic acid, from which the corresponding amino compound has been obtained. The authors have isolated a new isomeric acid, which is simultaneously formed, and contains the nitro group in one of the ortho-positions to the chlorine atoms. The new 1.2-dichloro-3- or -6-nitrobenzenesulphonic acid yields an amino-acid on reduction. On diazotising this substance, and treating the solution with an alkali, one of the chlorine atoms is split off, and replaced by a hydroxyl group. The new nitro- and amino-1.2-dichloro-benzene-4-sulphonic acids and their sodium salts are all more soluble in water than their isomerides. Separation of the nitration products may thus be conveniently effected by crystallisation from water, either before or after reduction.—H. L.

Dyestuff derived from salicylthioacetic acid; Process for producing a red vat-dyeing —— [*Thio-indigo Red*] *similar to indigo.* Soc. pour l'Ind. Chimique à Bâle. Fr. Pat. 362,876, Jan. 31, 1906. Under Int. Conv., Oct. 30, and Nov. 4, 1905.

SEE Eng. Pat. 4687 of 1906; this J., 1906, 470.—T. F. B.

Thioindigo Red. H. Alt. Färber-Zeit, 1906, 17, 169—171 and 185—189.

AFTER describing the preparation and properties of this new dyestuff (see this J., 1906, 367 and 424) the author discusses in detail its application in dyeing and printing. It is well adapted to the dyeing of woollen tissues from a fermentation or hydrosulphite vat, and as the leuco compound only oxidises slowly, shades of remarkable evenness are obtained. In cop-dyeing very useful effects are produced in combination with indigo, whilst by topping the red with other fast dyestuffs it is possible to obtain a great variety of shades, which are distinguished by their fastness. Equally good results are obtained in hank and loose wool dyeing. Unlike indigo, Thioindigo Red is characterised by its great resistance to oxidising agents and it is therefore well adapted for use as a bottom colour in combination with fast wool dyestuffs worked in a chrome bath, or chromed after dyeing. Cotton may be readily dyed from a hydrosulphite or iron sulphate vat, or in a sodium sulphide bath. The leuco body, however, possesses little affinity for the vegetable fibre, and in order to obtain heavy shades it is necessary to employ strongers vats containing from 15 to 20 grms. of dyestuff per litre. It is well adapted for mercerised cotton yarns and cloths, as it resists strong alkalis fairly well in the cold. For calico printing it may be used either as a direct colour or as a red discharge for direct cotton dyestuffs non-resistant to hydrosulphite.—D. B.

Dressing and thickening agents; Decomposition and solution of ——. G. and G. Tagliani. Z. Farben-Ind., 1906, 5, 241—257.

FROM an exhaustive series of experiments, it is concluded

that the best method of removing dressing and thickening agents from cotton threads and cloth is to soak the fabric for two hours in a 2—3 per cent. solution of "diastafor" (a preparation of native ferments, rich in diastase) at a temperature of 38° C. It is then squeezed, rinsed in water, and finally boiled with lye. *Diastafor* is stated to possess remarkable solvent properties not only for starch, but also for nitrogenous and proteid substances, such as gluten, gelatin, gum, and mucilage. Although the removal of thickening agents can be effected equally well by steeping the fabric at 100° C. in a solution of sodium carbonate or hydroxide containing a small quantity of glucose or glycerin, this plan is less expeditious and more expensive. For the treatment of printed goods the fabric is passed through water to remove gum, it is then squeezed, soaked for 30—60 minutes in a 3 per cent. solution of "diastafor" at 50°—60° C., and finally washed.—D. B.

English Patents.

Oils, fats, or the like; Manufacture of viscid or fluid emulsions of —— [*for lubrication of textile fibres*]. O. A. H. H. Koesters. Eng. Pat. 4688, Feb. 26, 1906. XII., page 767.

Cellulose articles; Direct production of coloured ——. F. and A. van den Bosch and O. Müller. Eng. Pat. 6042, March 22, 1906. XIX., page 775.

Silk; Manufacture of artificial ——, *from viscose.* Soc. Franç. de la Viscose, Paris. Eng. Pat. 8045, April 3, 1906. Under Int. Conv., April 3, 1905.

See Fr. Pat. 361,319 of 1905; following these.—T. F. B.

Viscose; Manufacture of lustrous threads, bands, strips, and the like of ——. M. Müller, Altdamm, Germany. Eng. Pat. 10,094, April 30, 1906. Under Int. Conv., May 1st, 1905.

In place of the usual precipitating bath employed for converting viscose solutions into lustrous threads, bands, films, and plates, which is stated to be composed of a solution of acids or ammonium sulphate, the author employs a bath containing 40 kilos. of sodium bisulphate, 7 kilos. of 66 per cent. sulphuric acid, and 60 litres of water. This bath is stated to produce a satisfactory result, and to be cheaper than one prepared from ammonium sulphate.—H. L.

Gassing machines for yarn or thread; Apparatus for supplying a uniform mixture of gas and air, chiefly intended for use with ——. H. B. Arundel and J. Higginson, jun., Stockport. Eng. Pat. 15,065, July 21, 1905.

The gas and air are raised separately, before mixing, to a uniformly maintained pressure, by independent but similar apparatus, each consisting of a pump or fan in combination with a regulating and relief chamber. The gas, for example, is delivered by a pump into a bell floating in a water tank, the bell being loaded so as to maintain the desired pressure. A vertical pipe, attached to the under side of the crown of the bell, and having openings at its upper end, slides within a vertical pipe communicating with the gas-supply pipe to the pump. The pump is run continuously at a uniform speed, whatever the rate of gas consumption; when the latter falls, the gas delivered to the bell simply returns down the vertical pipes to the pump, and a circulation of gas is maintained without affecting the speed of the pump.—H. B.

Fabrics, felts, yarns, slivers, and the like; Method of and machinery for treating —— *with liquids, emulsions, gases, vapours, or dusts.* R. Hardcastle, Mexborough-in-Wharfedale, Yorks. Eng. Pat. 13,356, June 28, 1906.

The method, which is applicable to dyeing and similar purposes, consists in forcing liquids through the material by pressure, as the latter is caused to travel before the orifices of a pressure chamber, from which such liquids are forced. The fabric is pressed against a flat, stationary slotted frame provided for the passage of the liquid with one or more slots of sufficient length to extend along the entire width of the material. The liquid is impelled through the material in a continuous and even stream, so that every part is subjected to an equal treatment, and after passing through the material it enters a receiving chamber. The material may also be pressed against a slotted plate forming the outlet of the pressure chamber by a suitable plate or backing frame slotted in the manner above mentioned. This latter plate may form the face of a receiving chamber. The material while under treatment is preferably immersed in a body of liquid contained in a vat.—D. B.

Dyeing; Processes of cold ——. C. Henry, Paris. Eng. Pat. 13,714, July 4, 1905.

See Fr. Pat. 355,391 of 1905; this J., 1905, 1227.—T.F.B.

Sponges; Method of dyeing ——. T. Asher, Duisberg, Germany. Eng. Pat. 14,866, July 19, 1905.

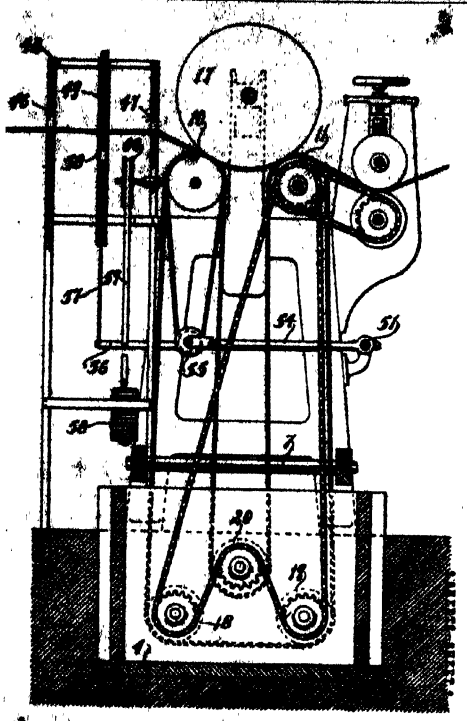
See Fr. Pat. 356,176 of 1905; this J., 1905, 1228.—T.F.B.

Dyeings; Production of stable ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 22,331, Nov. 1, 1905.

See Fr. Pat. 359,466 of 1905; this J., 1906, 373.—T.F.B.

Aniline Black; Dyeing wool or other animal fibres with ——. G. Bethmann, Leipzig, Germany. Eng. Pat. 26,962, Dec. 27, 1905.

The method consists in well washing and steeping the goods in alkali and water, then treating them with acid, and finally, after an eventual washing in water and a subsequent squeezing, impregnating them with an Aniline Black padding mixture containing only such a percentage of sodium chloride as is required for the purpose of developing the dyestuff. After steaming or ageing, the goods are treated with sodium bichromate in the usual manner. In this way wool can be dyed entirely without any preceding or simultaneous oxidation and injurious effects to its quality.—D. B.



Aldehyde-hydrosulphite salts [*Discharges*]; *Manufacture of* ——. G. B. Ellis, London. From Chem. Fabr. von Heyden Akt.-Ges., Radebeul, Saxony. Eng. Pat. 25,602, Dec. 8, 1905.

See Fr. Pat. 360,306 of 1905; this J., 1906, 475.—T.F.B.

United States Patents.

Washing fabrics; Apparatus for ——. I. E. Palmer, Middletown, Conn. U.S. Pat. 816,179, March 27, 1906.

The fabric passes between the rollers, 10 and 17, into the cleansing tank, 4, under the roller, 20, between the rollers, 17 and 11, and under the rollers, 19 and 18. From the tank the fabric now passes between spacing bars, 7, which gradually feed it along the roller, 10, so that it makes several passages through the tank, receiving alternate washings and squeezings, before finally leaving the apparatus. About midway of the length of the rollers, 10 and 11, the fabric, instead of passing under the roller, 20, passes round a pulley, 55, and then upwards over the roller, 10, and along the same course as at the commencement. The pulley, 55, is mounted on an arm, 54, which is fixed to a rock-shaft, 51, the latter being also connected to an arm, 56, which actuates, by an arm, 57, the slide, 49, so that a change in tension on the fabric, acting on the arm, 54, raises or lowers the slide, 49. The fabric enters the apparatus through openings, 45 and 47, in the skeleton frame, 43, and passes also through an intermediate opening, 50, in the slide-bar, 49. The tension device is counterbalanced by a weight, 58, attached to the arm, 54, by a flexible connection, 59, the latter passing over a guide-pulley, 60. If the guide-bar, 49, is raised or lowered, the tension on the fabric is diminished

or increased, and this may be made automatic at any desired tension by adjusting the weight of the counter-balance, 58.—B. N.

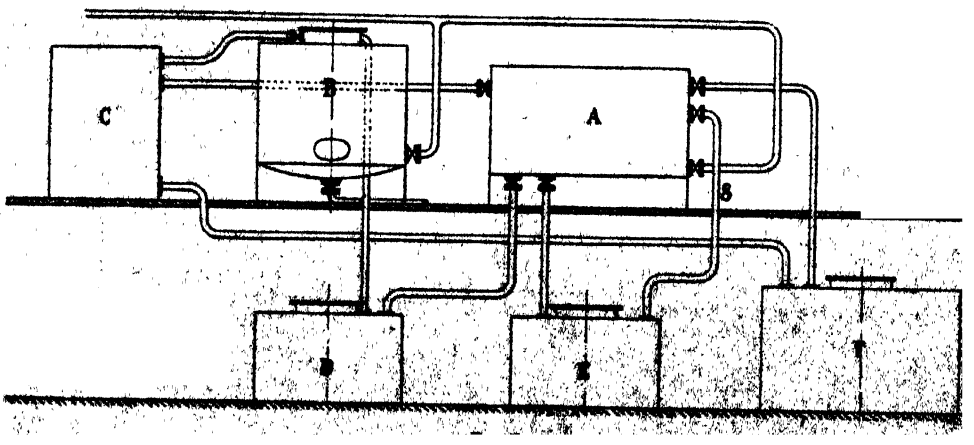
Dyeing machine [for yarns]. J. Hussong, Camden, N.J. U.S. Pat. 822,844, June 5, 1906.

The yarns to be dyed are suspended in the form of hanks from sticks, carried by a frame, in a dye vat divided into two compartments by a vertical partition extending nearly to the top and bottom, and provided with a perforated false bottom, placed some distance above the bottom of the vat, a perforated false top mounted on the frame above the sticks to ensure the proper circulation of the liquor in the vat, and a screen between the sticks and the perforated partition to keep the hanks in position when the dye-liquor is caused to flow upwards through the hanks. The vat, when in use, is closed by a cover. Reversible mechanism, e.g., a turbine, is placed in one of the compartments to circulate, alternately in opposite directions, the liquor in the dye-vat.—E. B.

Warp-printing devices; Printing mechanism for ——. E. Schmidt, Oberschöneweide, Germany. U.S. Pat. 822,308, June 5, 1906.

Warp-yarns, spread upon a printing-drum, are printed by means of a number of sets of travelling "printing-rollers," to which colours are supplied from boxes suspended from a series of transverse bars carried by a pair of "suitably supported endless belts." The "rollers" press against the yarns "simultaneously and with a bodily-reciprocating movement parallel with the axis of the drum."—E. B.

French Patents.



Viscose threads [Artificial silk]; Impts. in spinning ——. Soc. Franç. de la Viscose. Fr. Pat. 361,319, April 3, 1905.

With the object of preventing individual filaments of viscose from adhering to one another when a number of them are twisted together to produce threads suitable for weaving purposes, a mixture of an alkali (sodium or potassium) aluminate and an alkali silicate is either added to the solution from which the filaments are formed, or is employed, in place of the ferrous sulphate hitherto used for the same purpose, in a bath through which the filaments are passed immediately after their formation. The first of these methods is to be preferred. The threads obtained, it is stated, besides being silky in appearance and to the touch, dye very regularly.—E. B.

Ramie and analogous textile materials; Process and apparatus for decorticating and degumming ——. J. Bendel. First Addition, dated Dec. 14, 1905, to Fr. Pat. 338,752, April 15, 1903 (this J., 1904, 748).

Perforated or reticulated frames, made in parts hinged together, are employed to carry the strips of ramie during the treatment to which they are subjected for the purpose of degumming, &c. In softening and degumming the ramie, the frames are hung over rods fitted into two concentric supporting rings, connected together by cross-bars. The fibrous strips are thus immersed in the necessary baths contained in circular tanks. To decorticate the fibres, the frames with the strips upon them are passed through an apparatus from which fine jets of water are sprayed.—E. B.

Wool in the unmanufactured state and in the form of fabrics; Extracting —— with volatile solvents. H. Lecouflet. Fr. Pat. 362,220, Jan. 5, 1906.

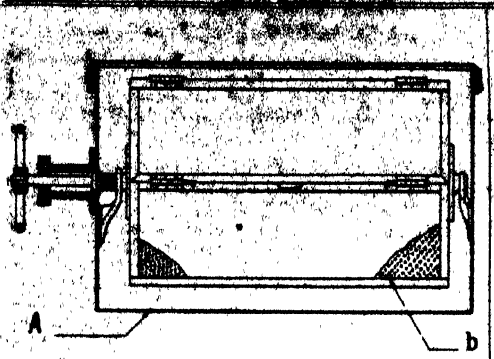


FIG. 2.

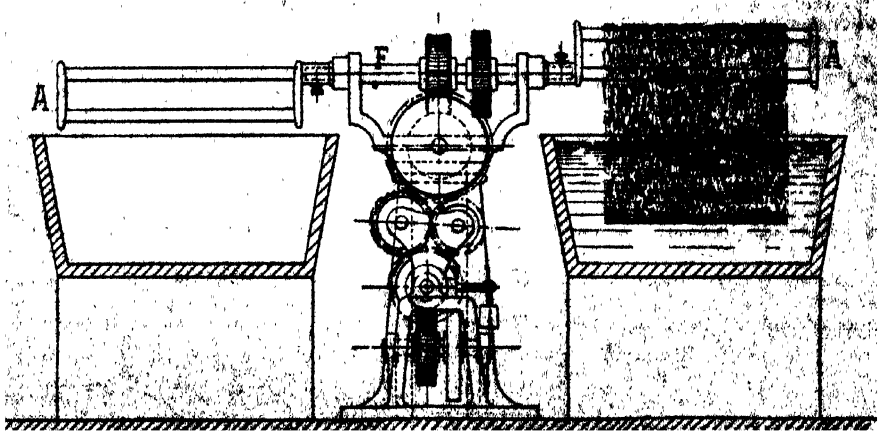
A PERFORATED, rotatable cylinder, *b*, (see figures), is filled with the greasy wool or woollen tissues, &c., to be extracted, and placed within a vessel, A, which is then closed by an air-tight lid. A grease solvent, *e.g.*, light petroleum, is then conveyed into the vessel, A, from a tank, F. After the cylinder has been revolved for a while in this, the solvent is withdrawn to a tank, E. A further quantity of "pure" solvent is thereupon introduced into the vessel, A, to complete the extraction of the fatty matters present in the wool. This also, after use, is run into the tank, E. The solvent retained by the wool is next expelled by means of steam, the vapours passing to a vessel, C, where they are condensed, the solvent thus recovered returning to the tank, F. The extracted wool is then removed from the cylinder, *b*, and replaced by a second charge of greasy wool, the latter being treated, first, with the impure solvent in the tank, E, which is then passed into a tank, D, and, afterwards, with "pure" solvent from the tank, F. Further lots of wool are treated in the same manner, the solvent being taken from the tank, D, to a still, B, and the purified solvent passing to the tank, F, while the extraction operations are proceeding.—E. B.

Indigo white preparations suitable for use in vats, particularly in fermentation vats; Process for obtaining ——. Farbw. vorm. Meister, Lucius, und Brüning. First Addition, dated April 6, 1905, to Fr. Pat. 352,695, March 6, 1905.

See Eng. Pat. 7390 of 1905; this J., 1906, 530.—H. L.

Bleaching and dyeing bobbins; Spindles for —— *in* ——. A. Rolls and Co. Fr. Pat. 362,318, Jan. 16, 1906.



THE perforated spindles used in bleaching or dyeing cops or cheeses are provided with a grooved attachment against which the ends of the cop or cheese may be pressed. The object of the device is to prevent the liquor from finding a channel between the tube and the cop or cheese, and to ensure a thorough penetration of the material.—H. L.

Cotton on bobbins; Process and arrangement for the winding of —— *for dyeing or mercerising.* P. Fontaine. First Addition, dated Jan. 18, 1906, to Fr. Pat. 359,302 of Nov. 10, 1905.

SEVERAL bobbins with rigid perforated cores are mounted around the same spindle as an axis, alternate bobbins being of the same diameter. A core of smaller diameter is thus between two cores of greater diameter, and the smaller is able to penetrate into the larger when the whole is subjected to pressure from the screw at the end of the spindle. The cotton of the superposed bobbins then forms a continuous muff.—B. N.

Yarns in the form of hanks; Machine for boiling-off, charging, dyeing, and washing ——. See, C. Durand et Cie. Fr. Pat. 361,288, March 29, 1905.

THE yarns to be dyed, &c., are suspended in the form of hanks from reels, A (see Fig. 1), eccentrically fixed to rods, F, which are driven by suitable mechanism, so that neighbouring ones rotate in opposite directions, to the end that adjacent portions of the hanks shall ascend or descend together (see Fig. 2). This arrangement, it is claimed, while allowing the hanks to move in close proximity to one another, prevents them from becoming entangled. The reels, when required, are mechanically raised, to allow them to be removed and replaced, and the baths to be changed.—E. B.

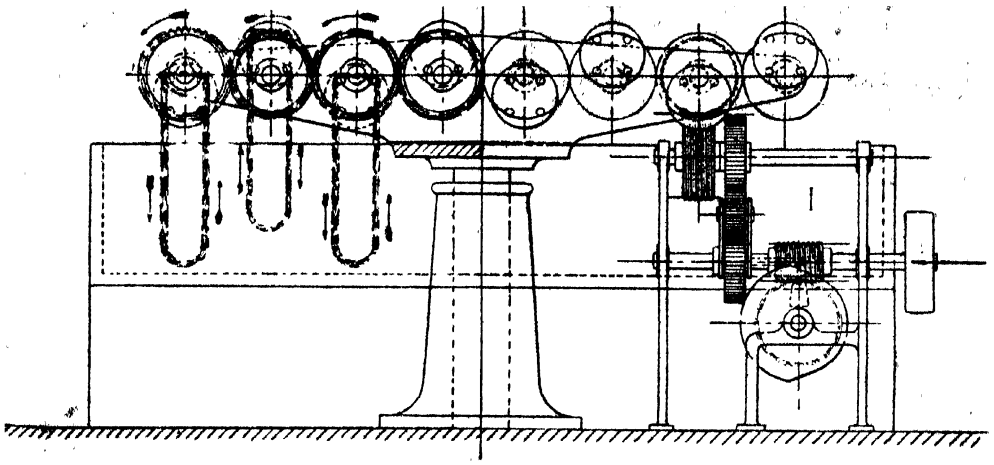


FIG. 2.

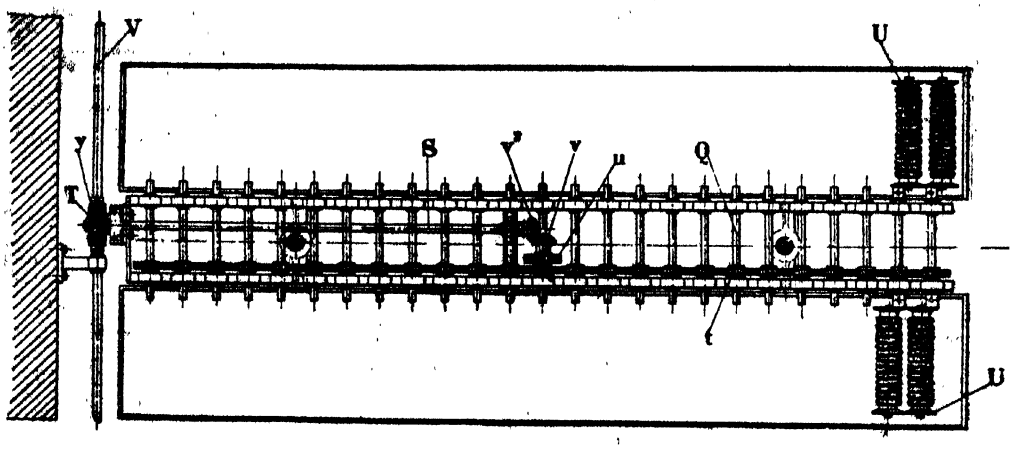


arms composed of silk, cotton, &c.; Machine for dyeing, in the form of hanks,——. J. Garel. Fr. Pat. 368,261, Jan. 6, 1906.

Two sets of reels, U (see figures), are eccentrically attached to the opposite ends of a number of short shafts, Q, mounted upon a supporting frame, and carrying wheels, *t*, gearing in line one with another. A shaft in the middle of the series has keyed upon it a second gear-wheel, *u*, by means of which motion is transmitted, through a transverse shaft, S, by the intermediary of the wheels, v^2, *v*, to the wheels, *t*, and thence to the reels, U. The reel-carrying frame is attached to an overhead carriage in such a manner that it can be raised and lowered by means of gearing, and, when raised, can be run sideways upon rails upon which it rests. To actuate the reels, the framework is lowered into position so that the worm-wheel, T, at one end of the shaft, S, comes into gear with an endless screw, *y*, keyed upon the main driving shaft, V. When the hanks to be dyed have to be treated in two or more baths, they are treated for a sufficient length of time in the first of those, and the framework bearing the hanks is then raised, and moved until it is directly above the tanks containing the second bath. It is thereupon lowered, the reels, &c., set in motion as before, and the hanks further treated as required. Much time and labour are thus saved.

—E. B.

GERMAN PATENT.

Cellulose threads and films; Process for preparing transparent, durable, and elastic ——. Vereinig. Glanzstoff-Fabr. A.-G. Ger. Pat. 169,567, Jan. 17, 1905. XIX., page 775.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page 693.*)

FRENCH PATENT.

Wood, metals, and other substances; Product adapted for the coloration and preservation of ——. Soc. Mass et Rose. Fr. Pat. 361,378, April 14, 1905.

THE process consists in treating or impregnating wood and other materials with a solution containing coal-tar dyestuffs, especially certain azo dyestuffs, alcohol, and commercial pyroligneite of iron—*e.g.*, aminoazobenzene sulphonic acid (Fast Yellow), 10 parts; alcohol, 85 parts;

and pyrolignite of iron, 30° B., 5 parts. It is claimed that pyrolignite of iron acts as a powerful antiseptic, besides fixing the dyestuffs. The process is stated to be of value for preserving and colouring metals, paper, linoleum, and in particular all kinds of wood.—H. L.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 697.)

Chromic acid; Action of —— on hydrogen iodide. K. Seubert and J. Carstens. Z. anorg. Chem., 1906, **50**, 53—66.

The speed of reaction between chromic acid and potassium iodide is proportional to the quantity of free mineral acid added, that is, to the number of hydrogen ions. The reaction is in its first stage a tri-molecular one, the components being hexavalent chromium, and iodine and hydrogen ions. The nature of the intermediate products after this first stage can at present only be surmised, but all the chromium is finally reduced to the chromic condition, and for every atom of chromium three atoms of iodine are liberated, as indicated by the simple equation :—$CrO_3 + 3HI = Cr(OH)_3 + 3I$.—F. Sodn.

Magnesium oxide; Physical properties of fused ——. H. M. Goodwin and R. D. Mailey. Trans. Amer. Electrochem. Soc., May 1, 1906. [Advance Proof.]

For the preparation of rods of the fused oxide an electrically heated graphite tube was employed, pure magnesium oxide being fed into the tube, which was protected on the outside by a jacket of powdered coke. Owing to a reaction between the carbon and magnesia at high temperature, it was impossible to obtain rods as large as the internal diameter of the tube. An arc furnace was subsequently employed, and from blocks of fused oxide thus obtained, rods were cut suitable for the tests which were carried out. The surface of the white fused oxide resembles glazed porcelain; the crystalline structure becomes more coarse the slower the cooling. The hardness is between that of apatite (transparent variety) and felspar (white cleavable variety). The specific gravity (mean of three samples) is 3·493 at 20° C. The melting point, estimated with an optical pyrometer, was found to be approximately 1920° C. The electrical conductivity was measured: below 1100° C. magnesium oxide is a much better insulator than porcelain, but above that temperature its large temperature coefficient indicates that it probably becomes a better conductor than porcelain. The coefficient of expansion, measured with an Abbe-Fizeau dilatometer, is not much greater than that of quartz crystal cut parallel to its optic axis, and is nearly equal to that of platinum, which fact will doubtless be of value in constructing apparatus for high temperature work. Chemically the fused oxide is very inert towards many neutral salts at high temperatures; the alkalis, however, attack it energetically.—R. S. H.

Ferric hydroxide and oxide; Pseudomorphs of —— after ferric sulphate. A. Vesterberg. Ber., 1906, **39**, 2270—2274.

Into a 250 c.c. flask are poured 50 c.c. of water and 50 c.c. of concentrated sulphuric acid, and 5 grms. of reduced iron are added. After the stormy evolution of gas has ceased, the flask is heated till the water is driven off, and the acid boiled till the iron is completely converted (about two days) into ferric sulphate. After cooling, the acid is poured off as far as possible, the magma of crystals poured into 100 c.c. of water, and then this is poured, with constant stirring, into 100 c.c. of strong solution (1:2) of sodium hydroxide. The resulting hydroxide is washed free from alkali by long heating on the water-bath with successive quantities of water. On drying in the air, it is seen under the microscope to consist of pseudomorphs of the ferric sulphate, and these pseudomorphs persist when the hydroxide is converted into oxide by ignition, though they are very friable and easily powdered.—J. T. D.

Potassium chlorate and nitrate; Isomorphism between ——. [Separation of isomorphous bodies.] J. Herbette. Compt. rend., 1906, **143**, 128—130.

Of the two forms in which potassium nitrate crystallises, one is isomorphous with potassium chlorate, but not the other, only one form of this latter salt being known. A similar relationship has been observed between the tartrates of potassium and thallium. These facts are capable of practical application in the separation of such isomorphous bodies. It has been found that if salts A and B have only one form in common, A may be isolated, quite free from B, by choosing conditions which render crystallisation in the common form impossible.—F. Sodn.

Borates; Potassium and sodium ——, [and determination of boric acid in alkali borates]. M. Dukelski. Z. anorg. Chem., 1906, **50**, 38—48.

The author has by a study of equilibrium in the system whose components are K_2O (or Na_2O), B_2O_3, H_2O, ascertained the formulæ of all the borates capable of stable existence in the solid phase at 30° C. They are :—$K_2O,B_2O_3,2{\cdot}5H_2O$; $K_2O,2B_2O_3,4H_2O$; $K_2O,5B_2O_3,8H_2O$; $Na_2O,B_2O_3,4H_2O$; $Na_2O,B_2O_3,8H_2O$; $Na_2O,2B_2O_3,10H_2O$; and $Na_2O,5B_2O_3,10H_2O$.

For the analyses, the mannitol method of estimating boric acid was found to give very accurate results when carried out as follows :—The alkali was first titrated with hydrochloric acid, using methyl orange as indicator. The solution was then boiled, under a reflux condenser, to expel all carbon dioxide, and the boric acid titrated with caustic soda and phenolphthalein in presence of mannitol. It is important that the mannitol be in sufficient quantity, and that the volume of liquid for titration be not too great.—F. Sodn.

Lead peroxide; New process for the manufacture of ——. L. Friderich, E. Mallet, and P. A. Guye. Monit. Scient., 1906, **20**, 514—518.

Normal or basic lead sulphate can be converted into lead peroxide with a nearly theoretical yield, by mixing it with magnesia, suspending the mixture in water, and passing in chlorine. In a trial with 5 kilos. of lead sulphate in a rotating barrel of 25 litres capacity, the operation was completed in about three hours, and required: Water, 13 litres; magnesia, 1·2 kilos.; and chlorine, 1·2 kilos. The crude reaction-product obtained contains at least 90 per cent. of lead peroxide, and by purification first with caustic soda, and then with acid, a product of 97 per cent. purity can be obtained, containing only traces of chlorine. The cost of production of 100 kilos. of lead peroxide is given as follows :—

		Francs.
36 kilos.	of magnesia at 7 francs per 100 kilos	2·50
33 „	„ chlorine at 15 „ „ „	4·95
146 „	„ lead sulphate at 23 „ „ „	33·58
Labour, &c.	.....	3·00
Total	.....	44·03

—A. S.

Mercuric iodide; Isomorphism of —— with zinc and cadmium iodides. A. Duboin. Compt. rend., 1906, **143**, 40—41.

From solutions of zinc and mercury iodides, or cadmium and mercury iodides, left to evaporate, successive crops of crystals are obtained containing progressively less mercury and more zinc or cadmium, the relative quantities of the two bearing no necessary relation to their atomic weights. Mercuric iodide thus appears to be completely isomorphous with zinc or cadmium iodide.—J. T. D.

Phosphorus trisulphide. R. Boulouch. Compt. rend. 1906, **143**, 41—44.

The author finds that when any substance containing phosphorus and sulphur in proportions between those corresponding to the formulæ P_2S_5 and P_2S_3, is fused, and suddenly cooled, and treated with carbon bisulphide,

an insoluble pulverulent portion remains, and a viscous portion dissolves. Continued repetition of this process, both in the pulverulent portion, and on the viscous portion recovered by evaporating the solvent, ultimately separates the substance completely into P_4S_3 and P_2S_5. The substance, P_3S_3, is thus not a definite compound. —J. T. D.

Phosphorus chloronitride. Besson and Rossett. Compt. rend., 1906, **143**, 37—40.

This substance is best produced by heating together phosphorus pentachloride and ammonium chloride, washing, drying, and redistilling the distillate. It has the molecular formula, $(PCl_2N)_3$, is a white solid substance resembling a carbon compound, and soluble in most organic solvents. Water slowly decomposes it, forming ammonia and hydrochloric and phosphoric acids. Sulphuric anhydride appears to form a compound with it, as does also nitrogen peroxide, but these compounds are exceedingly unstable, and their composition has not been established.—J. T. D.

Carbon; Solubility of —— in calcium carbide. H. M. Kahn. Compt. rend., 1906, **143**, 49—51.

At a high temperature, calcium carbide can dissolve carbon. Heated for 3½ minutes with currents rising from 400 to 600 ampères at 110 volts, the percentage of carbon dissolved, rose from 0·5 to nearly 4·0; with a constant current of 500—600 ampères, the percentage dissolved, increased with the time from 2½ in 3½ minutes to 5 in 6½ minutes.—J. T. D.

Vinasse; Treatment of —— at the Raab spirit factory. J. Ginsberg. XVII., page 771.

Vanadium salts; Electrolytic preparation and properties of ——. L. Marino. XIA., page 765.

Arsenic; Production of ——. Oil, Paint, and Drug Rep., July 16, 1906. [T.R.]

The annual report of the U.S. Geological Survey gives the following particulars of the production of arsenic:—

Production.—In 1905 there was produced in the United States 1,507,386 lb. of white arsenic (arsenious oxide), valued at $35,210, as compared with 72,413 lb., valued at $2185, in 1904. There are signs that the production of arsenic in this country will show marked expansion in the near future, and it is hoped that the chemical manufacturing industry utilising arsenic will progress also.

The following table shows the production of arsenic in the United States in the last five years:—

Year.	Lb.	Value.
		Dols.
1901	600,000	18,000
1902	2,706,000	81,180
1903	1,222,000	36,691
1904	72,413	2,185
1905	1,507,386	35,210

The peculiar feature of the domestic industry is the irregularity shown in production, which is unlike the status of the foreign industry as reported in recent years.

Imports.—The significance of the importation of arsenic and its compounds for the manufacturing industries of the United States may be appreciated from the statistics given in the following table for the period 1900 to 1905 inclusive:—

Year.	Lb.	Value.
		Dols.
1900	5,765,859	265,209
1901	6,989,588	313,782
1902	8,119,866	390,655
1903	8,557,961	394,602
1904	6,896,283	343,380
1905	7,675,962	256,540

World's production.—A noteworthy feature of the industry has been the growth in the production of Spain, which shipped to the United States in 1905 approximately 1750 short tons of white arsenic (99·8 per cent. of arsenious oxide). The largest producer of metallic arsenic and arsenious oxide in the world is Germany. Hopes are entertained that Canada may become an important producer with the development of its new deposits of mispickel in Ontario.

The following figures give the output of the principal producing countries during the last year for which statistics are available:—Canada (1905), 54 metric tons, value $5400; Germany (1904), 2,800 tons, value $244,917; Italy (1901), 6 tons, value $120; Japan (1903), 6 tons, value not given; Portugal (1904), 1370 tons, value $58,887; Spain (1903), 1088 tons, value $87,040; United Kingdom (1904), 992 tons, value $27,795; United States (1905), 684 tons, value $35,210.

English Patents.

Hydrochloric acid and gas-treating towers; Packing materials for ——. H. Hurlbutt, jun., Mold, and F. Hurlbutt, Queen's Ferry, Flintshire. Eng. Pat. 17,198, Aug. 25, 1905.

A series of raised bands or ribs are run horizontally round the surfaces, and preferably at right angles to the axes of the packing pieces for acid-treating towers, which ribs cause the acid flowing down to break up and spray over all round, as a fountain or waterfall. The packing pieces, of earthenware or other suitable material, are preferably formed in hollow lengths, of any desired cross-section; and the ribs may be formed of any convenient section, as semicircular or rectangular, and may be on either or both the exterior and interior surfaces.

(Reference is directed to Eng. Pats. 14,774 and 20,290 of 1896, and 23,052 of 1900; this J., 1896, 700; 1901, 897.)—E. S.

Nitric acid or nitric oxide; Processes for the production of —— from atmospheric air. H. Pauling, Gelsenkirchen, Germany. Eng. Pat. 7870, April 2, 1906.

In order to produce nitric oxide or nitric acid, air, or a mixture of air with oxygen, is heated to about 1200° C.; a portion of the products of the reaction is then withdrawn, cooled, and blown into the air under treatment, in order to cool the latter without causing it to be rarefied by the introduction of a foreign gas.—E. S.

Nitric acid; [Electrical] Production of pure —— [from air]. H. Pauling, Gelsenkirchen, Germany. Eng. Pat. 7871, April 2, 1906.

Air is subjected to the action of electrical discharges and water or aqueous vapour is added to the hot gases thus formed while they have a minimum temperature of 200° C., the quantity of such water or aqueous vapour being so proportioned as not to cool the gases below 100° C., so that the nitric vapours may remain gaseous. The gases are then passed through metallic pipes (in which, if desired, the mixture of the hot gases with water or steam may take place), and lastly, for condensation, into suitable clay apparatus. (See Fr. Pat. 323,760 of 1902; this J., 1903, 495.)—E. S.

Salt; Manufacture of ——. J. Hargreaves, Farnworth-in-Widnes, Lancs. Eng. Pat. 13,127, June 26, 1905.

Brine containing ferrous salts is treated with chlorine, or with sodium hypochlorite or the like, to convert the ferrous into ferric salts, the precipitation of which is facilitated by addition of "soda" or lime in excess. The heavy precipitate containing lime and magnesia thus formed carries down with it the finely-divided and suspended ferric hydroxide, and the brine, freed from the precipitate, yields, on crystallisation, salt of a "pure white colour."—E. S.

Common salt; Preparation of —— for domestic and other use. G. T. Holloway, London. Eng. Pat. 16,279, Aug. 10, 1905.

The coarser particles of common salt, freed from fine powder by screening, are agitated with about 1 per cent.

of their weight (in the case of kitchen salt) of finely powdered sodium carbonate. In some cases, the sodium carbonate so used is previously mixed with a portion of finely-powdered salt. The coarse salt thus becomes coated, and this coating serves the purpose of converting the deliquescent chlorides of magnesium and calcium present into non-deliquescent carbonates, at or near the surface of the granules.—E. S.

Acetates of copper and lime; Process for the manufacture of double ——. I. C. Ponthus, Lyons, France. Eng. Pat. 3536, Feb. 13, 1906. Under Int. Conv., Aug. 31, 1905.

See Fr. Pat. 357,414 of 1905; this J., 1906, 87.—T. F. B.

Sulphate of alumina and sulphate of potash; Separation of —— from solutions containing the same. A. Pezzolato and M. T. de Felice, Rome. Eng. Pat. 6122, March 13, 1906.

Solutions of crude potassium alum, such as are obtained by acting on alum stone or the like with alkali bisulphate or sulphuric acid, are treated with potassium sulphide solution to completely precipitate iron as sulphide, and aluminium as hydroxide, hydrogen sulphide being evolved. Potassium sulphate is crystallised out of the filtered solution. The precipitate is treated with sodium sulphide solution to obtain solution of sodium aluminate, which when cleared, is decomposed by hydrogen sulphide to precipitate aluminium hydroxide (subsequently converted into aluminium sulphate), and recover sodium sulphide. A portion of the potassium sulphate obtained as first described, is heated in a muffle furnace, and transformed into sulphide by causing hydrogen sulphide, evolved in preceding processes, to act upon it,

$$(K_2SO_4+4H_2S=K_2S+4S+4H_2O),$$

"thereby producing sulphur which is collected and utilised to prepare sulphuric acid."—E. S.

Alkali cyanides; Process for separating —— from their solutions in water. J. Tcherniac, London. Eng. Pat. 11,371, May 15, 1906.

Claim is made for separating alkali cyanides from their solutions, or for dehydrating a hydrated alkali cyanide, by adding solid caustic alkali. For example, a solution containing 30 per cent. of sodium cyanide is made by passing gases containing hydrogen cyanide into a solution of caustic soda containing a slight excess of alkali beyond the amount required, and a quantity of solid caustic soda, approximately equal to that originally contained in the solution, is added. The solution is now again nearly saturated with hydrogen cyanide, and a further quantity of solid caustic soda added, when about one-half of the sodium cyanide present separates in the form of a fine white powder. If the solution of sodium cyanide should become so concentrated that on cooling it sets to a mass of hydrated crystals, these can be converted into a sandy powder consisting of the anhydrous or less hydrated salt, by addition of solid caustic soda.—A. S.

Calcium hydride; Method of producing ——. Consortium für Elektrochem. Ind., Nurnberg, Germany. Eng. Pat. 11,767, May 19, 1906. Under Int. Conv., May 19, 1905.

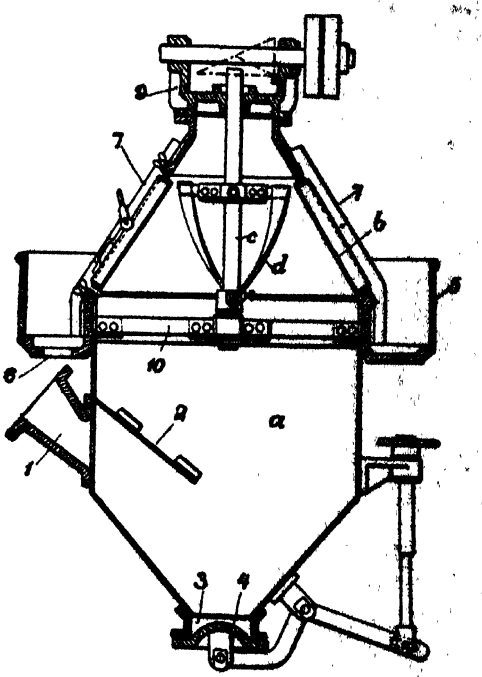
Calcium is melted, preferably in an iron vessel, and hydrogen is conducted into the molten metal. The hydrogen is rapidly absorbed, and the product may be removed from the crucible in solid lumps, described as containing 84 per cent. of calcium hydride (CaH_2). Calcium hydride is stated to be well suited for producing hydrogen for aërial navigation. (See this J., 1906, 363.)—E. S.

United States Patents.

Ammonia from gases; Process of extracting ——. R. Brunck, Dortmund, Germany. U.S. Pat. 825,297, July 10, 1906.

See Fr. Pat. 356,889 of 1905; this J., 1906, 13.—T. F. B.

Tin; Producing oxygen compounds of ——. C. E. Acker, Niagara Falls, N.Y., Assignor to Acker Process Co., N.J. U.S. Pat. 824,898, June 26, 1906.



A hypochlorite, such as calcium hypochlorite, is caused to react in presence of water on a tin chloride (stannous or stannic chloride), and the hydrated tin oxide which separates is calcined. The chlorine set free by the reaction is withdrawn in such manner as to be recovered without substantial admixture of air. (Compare U.S. Pat. 810,897, of Jan. 30, 1906; this J., 1906, 218.)—E. S.

Peroxide of hydrogen; Stable solution of ——. W. Heinrici, Halle on the Saale, Germany. U.S. Pat. 825,883, July 10, 1906.

See Fr. Pat. 356,880 of 1905; this J., 1906, 19.—T. F. B.

French Patents.

Liquids which are not easily filtered, such as milk-of-lime, and diffusion juice [from beet sugar factories]; Apparatus for purifying ——. H. Kořán. Fr. Pat. 362,646, Jan. 23, 1906.

The milk-of-lime or other liquid to be purified enters the reservoir, *a*, by the pipe, 1, and is forced to take a downward direction by the partition, 2. The larger particles of impurities such as sand, coke, unslaked lime &c., settle to the bottom, and are drawn off from time to time through the opening, 3, which is provided with a valve, 4; the milk-of-lime rises in the vessel, *a*, and passes through the fine metallic sieves, *b*, which are held in position by the angle-irons, 7, into the trough, 5, from which it flows away through the opening, 6. Agitator blades, *d*, carried by the shaft, *c*, supported on the cross angle-irons, 10, and driven from above by the mechanism, 9, give a downward direction to the finer particles of impurities which have been carried upwards by the liquid, so that only a very pure liquid reaches the sieves, *b*. As the inflowing liquid has to pass over the solids deposited in the conical bottom of the vessel, *a*, the latter are completely exhausted.—W. H. C.

Salts of the oxyhalogen acids; Electrolytic production of ——. Deutsche Solvay-Werke A.G. Fr. Pat. 362,737, Jan. 10, 1906. XIA., page 766.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 698.)

ENGLISH PATENT.

Glass-melting and pouring apparatus. P. T. Sievert, Dresden, Germany. Eng. Pat. 5605, March 8, 1906. Under Int. Conv., March 11, 1905.

THE molten glass flows from the melting-bath into a device consisting of a movable carrier placed in a heating-chamber arranged in front of the furnace. This carrier is placed on a section of the wall of the closed heating-chamber, which section can be removed from the wall for the purpose of emptying the carrier, the latter being surrounded on all sides, and especially on the bottom, by hot gases. The movable section of the wall may either be carried on a vertically-moving carrier, or else the carrier or the section of the wall may be hinged, so that the carrier can be tipped about the joint or hinges, and emptied.—A. G. L.

Blast-furnace slag; Relation between the hydraulic properties and chemical composition of granulated ——. L. Jesser. Tonind. Zeit., 1906, 739; Chem.-Zeit., 1906, **30**, Rep. 225.

No perfect concordance can be traced between the hydraulic properties and chemical composition, the hardness of the cement being greatly influenced by the method of granulation in water, and the further treatment of the slag. The ratio of silica to alumina, however, has an undeniable effect on the hydraulic properties, though—the proportion of lime remaining constant—no regular decrease in strength can be detected between the ratios 1 : 0.5 and 1 : 0.3. The lime content also influences the hydraulic properties. The border line between good and inferior slags with a minimum content of lime may be expressed by the ratio silica 1:alumina 0.25:lime 1.4, the respective proportions by weight being: 1:0.76:0.32.
—C. S.

Cement; Researches on reinforced——, and the influence of the removal of stress. F. Schüle. Compt. rend., 1906, **143**, 28—30.

THE experiments were made on:—1. Two series of prisms or briquettes arranged for tensile stress. 2. Rectangular beams, armoured and unarmoured, 170 cm. long, loaded at two points 30 cm. apart. 3. Beams of T-section, 430 cm. long, loaded at seven points 50 cm. apart. In each case, starting with a certain load, the load was increased considerably, and after deformation or extension, the load was diminished to its original value. In the first set of experiments, a considerable permanent or residual deformation occurred; and, even after fissures appeared in the cement, the adhesion of cement to iron caused considerable residual stress, tension in the iron, compression in the cement. In the second set of experiments, the hypothesis of plane sections remaining planes after deformation was not realised; the actual tensions in the extended zone were always less than those calculated from the hypothesis, because of internal stresses due to the adhesion of metal and cement. The ratio of permanent to total deformation was found to be greatest when the load was just sufficient to produce the beginnings of fissure in the extended zone of the beams. In the third set there were two series of experiments; one with beams which had been made a year, the other with beams only six weeks old. The breaking stresses of the latter series were only two-thirds of those of the former; in both series the permanent deformation varied from 5 to 40 per cent. of the total deformation. The repeated application of a stress uniformly distributed over the length of the beam produced fissures not merely at the middle point, but over half the length of the one year old beams, and three-quarters of the length of the six weeks old beams. By this process, the adhesion of metal to cement was destroyed before the tension in the iron had reached half the elastic limit. Five of six one year old beams broke at the middle just after the elastic limit of the iron had been exceeded; the other gave way at the extremities under a smaller load. The six weeks old beams all gave way at the ends below the elastic limit of the iron.—J. T. D.

ENGLISH PATENTS.

Kilns for burning bricks, tiles, and the like; Impts. in ——. A. C. Brewerton, Reading. Eng. Pat. 13,036, June 23, 1905.

THE claim relates to improvements in kilns described in Eng. Pats. 3628 of 1876, and 15,659 of 1899. In addition to the usual chimney flue, the kilns are connected together in groups by one or more flues connected to the top of the kilns, and provided with suitable dampers. By manipulating these dampers, the hot gases coming from a kiln which has been burnt off can be sent to another kiln which has been recently charged. The gases pass down through the contents to the main flue, and serve to heat the bricks, &c., prior to the admission of the fire-gases which are to complete the burning. The hot gases may also be passed beneath a drying floor on which the bricks or tiles are stacked before being put into the kilns.—W. H. C.

Clays; Cleaning and separating ——, *and apparatus therefor.* M. Bohn, Nagy-Kikinda, Hungary. Eng. Pat. 1105, Jan. 15, 1906.

THE clay to be cleaned is advanced along the interior of a horizontal cylinder by means of a screw-conveyor placed therein. The lower part of the cylinder consists of a series of sieves of different sized meshes. As the screw-conveyor fits closely against these, it pushes the clay through the holes in the sieves, and keeps the latter clean at the same time, the clay thus being graded into its components according to their size. Any stones, &c., are pushed through to the end of the cylinder, and emerge by a suitably sized opening.—A. G. L.

UNITED STATES PATENT.

Marble and stone; Manufacture of artificial ——. T. M. Thom, Cheshunt. U.S. Pat. 825,068, July 3, 1906.

SEE Eng. Pat. 8804 of 1905; this J., 1906, 537.—T. F. B.

FRENCH PATENT.

Slag; Process for the manufacture of building stones, pipes, and briquettes from ——. Cöln-Müsener Bergwerks-Act.-Ver. Fr. Pat. 362,808, Jan. 29, 1906.

THE slag—for example, blast-furnace slag—is crushed or ground, mixed with water, with or without addition of lime, and then subjected in moulds to a pressure of several atmospheres of carbon dioxide or gases containing it.
—A. S.

X.—METALLURGY.

(*Continued from page* 700.)

Blast refrigeration; Different modes of ——, *and their power requirements.* J. E. Johnson, jun. Iron and Steel Inst., July, 1906. [Advance proof.]

THE author shows that the brine-circulation system of drying air by refrigeration used by Gayley (this J., 1904, 1148) is not the cheapest method with respect to power required and cost of attendance. The most economical method is that of direct expansion, the air being passed directly over the coils in which the ammonia is expanded,

instead of over coils in which cooled brine is circulated. In order to avoid the formation of much ice, the refrigeration is effected in two stages by the use of two ammonia compressor-cylinders, one working from a suction temperature of 36° F., and the other from a suction temperature of 15° F. Further economy is effected by cooling the incoming air by means of the outgoing cold air. It is claimed that by this regenerative, two-stage, direct expansion system, it is possible to dry the blast with less than half the first cost for plant, with much less attendance, and with one-third of the power required by the single-stage, non-regenerative, brine-circulation system. It is pointed out that from a commercial point of view there is no gain in cooling the air to too low a temperature, 32° F. being probably low enough in summer, and 22° F. in winter.—A. S.

Gas-engines; Application of large —— in the German iron and steel industries. K. Reinhardt. Iron and Steel Inst., July, 1906. [Advance proof.]

A REVIEW of (1) the extent of the application of gas-engines in iron-works and collieries in Germany; (2) the working results obtained, including the influence of purification on the gases; and (3) the present practice in the design of large gas-engines in Germany.

Coke; Comparison of Rhenish-Westphalian foundry and blast-furnace ——. F. Wüst and G. Ott. Stahl u. Eisen, 1906, **26**, 841—844.

THE authors have determined various chemical and physical constants of coke used in the Ruhr district for blast-furnace (36 samples) and foundry (26 samples) purposes, to ascertain whether the results would show differences which would account for the higher price of foundry coke. The minimum, maximum, and average figures extracted from the table of results are given below:—

	Blast furnace.			Foundry.		
	Min.	Max.	Aver.	Min.	Max.	Aver.
Ash ..... per cent.	6·74	14·30	9·48	7·30	13·07	9·85
Sulphur . ,,	0·77	1·52	1·10	0·73	1·58	1·08
Phosphorus ,,	0·013	0·047	0·022	0·013	0·047	0·022
Carbon .. ,,	81·94	89·66	87·35	83·35	90·19	86·64
Calorific value, grm.°C.	6621	7245	7058	6735	7288	7001
Sp. gr., apparent ..	0·77	1·00	0·90	0·69	1·02	0·89
,, real	1·72	2·09	1·87	1·85	2·02	1·92
Porosity, vol. per cent.	44·57	67·30	51·34	44·60	62·75	53·34
Crushing stress, kilos. per sq. cm.	85	200	127	61	194	113
Loss on heating in a stream of carbon dioxide	1·44	9·75	5·07	1·56	12·38	4·46

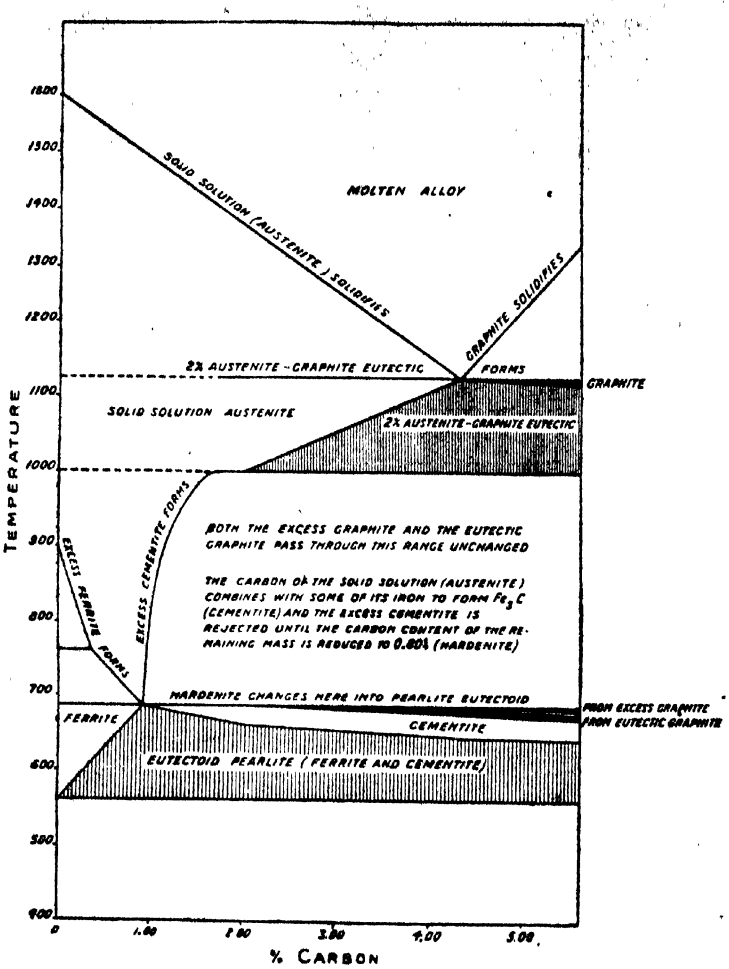
The results show that no difference can be thus established between foundry and blast-furnace coke; the only sensible difference shown is in the attack of the coke by carbon dioxide at a red-heat.—J. T. D.

Iron; Crystallography of ——. F. Osmond and G. Cartaud. Compt. rend., 1906, **142**, 1530—1532.

THE authors have previously found that the three varieties of iron all crystallise in the cubic system, and have now examined the effect of pressure on the crystal surfaces in producing slip or translation, and the position of macles. In α-iron, translation does not easily occur, but when it takes place, is parallel to the faces, a_1, of the octohedron; in β-iron there are no planes of translation; and in γ-iron translation parallel to the faces, a_1, occurs with ease. In α-iron, macling occurs as in fluorspar, but the plane of union is the face, a_2; no macles can be formed by reheating after deformation. In β-iron no macles are ever formed. In γ-iron, the macling is that of fluorspar, the plane of the macle and the plane of junction being the face, a_1, whether the macles be mechanical, or be made by reheating after deformation.

No crystallographic differences exist between the two allotropic forms of nickel.—J. T. D.

Iron; Crystallography of ——. F. Osmond and G. Cartaud. Compt. rend., 1906, **143**, 44—46.



A WELL-CRYSTALLISED piece of manganese steel, chilled in cold water from a temperature of about 1100° C., shows under the microscope a number of macles, parallel to the four faces of the regular octohedron. An etched polished section shows needle-like lines, parallel in each granule to two, three, or four definite directions. This is the martensite structure; it is produced by the stresses set up through the rapid changes of volume produced by sudden cooling. It is a structure proper to γ-iron; but it may remain, even after careful annealing, when the whole of the iron has reverted to the α-form, as a kind of pseudomorph. When that is the case, the granules are cut into a number of fine lamellæ parallel to four different planes, and the natural cleavages, p, of α-iron are interrupted; hence the fragility is lessened. This is the cause of the improvement of the mechanical qualities of mild steels by tempering. The martensitic structure is, on a small scale, that of octohedral meteoric irons. Such a structure is not peculiar to iron, but is general in all cases where in the solid state an allotropic change accompanied by change of volume occurs, if the resulting mechanical stresses can produce mechanical macles.

—J. T. D.

Iron-carbon alloys; Constitution of ——. A. Sauveur. Iron and Steel Inst., July, 1906. [Advance proof.]

THE author discusses the Roberts-Austen Roozeboom diagram relating to iron-carbon alloys (this J., 1901, 1016); whilst agreeing with previous workers as to the nature of the alloys immediately after solidification, and the transformations experienced by alloys containing less than 2 per cent. of carbon, he is unable to agree that in the case of alloys containing more than 2 per cent. of carbon, graphite plays any part in the transformations which take place after solidification. It appears to have been generally accepted hitherto, that when the iron contains more than 2 per cent. of carbon, the cementite present in the slowly-cooled alloy has been produced not only by the breaking up of austenite, but also by the direct union of graphite with some of the iron of the austenite. According to this view any graphite present in an iron-carbon alloy is due to "lag," i.e., to absence of favourable conditions (slow cooling, &c.), for the reaction of the graphite and iron, and consequently all cast irons free from silicon and other disturbing elements should normally be white. The author's view, on the other hand, is that the graphite which forms during solidification plays no part in the further transformation of the alloys, but acts merely as an inert substance, passing through the critical range unaffected. In the accompanying figure the composition of iron-carbon alloys after solidification, and after slow cooling, is shown, in accordance with this view. One of the chief arguments in favour of this view is the well-known behaviour of graphite, which resists transformation by any known heat treatment short of melting. Further evidence pointing in the same direction was afforded by the following experiments:—Some electrolytic iron was melted in a graphite crucible "brasqued" with magnesia, together with an excess of sugar charcoal, and the crucible was then allowed to cool very slowly in the furnace. Under such conditions, exceptionally favourable to the production of a pure iron-carbon alloy in a state of stable equilibrium, the resulting alloy should contain relatively little graphite, if this constituent plays any part in the formation of cementite. The alloy was found to contain 4·354 per cent. of total carbon, and should therefore theoretically contain 2·40 per cent. of graphite, whereas actually the amount of graphite was 3·666 per cent., so that not only had any graphite failed to combine with iron at the critical temperature, but some of the cementite had decomposed into carbon (temper carbon) and iron during the very slow cooling. A piece of this alloy was next heated for five hours at the critical temperature (1000° C.), when instead of additional cementite being formed by the interaction of graphite and iron, a considerable quantity of that constituent was decomposed, 1·688 per cent. of temper carbon being produced.

The causes of the great variations in the percentage of

graphite in commercial cast iron are :—(1) The presence of impurities, and (2) the rate of cooling. In order to obtain the theoretical proportion of graphite in an iron-carbon alloy, two conditions are essential: (1) very slow cooling during solidification, and (2) absence of disturbing foreign elements. The production of malleable cast-iron castings by annealing for a long time is easily and logically explained if graphite be regarded as a normal constituent of cast iron. White cast-iron is in an unstable condition, the formation of graphite having been prevented through too sudden cooling, or because of the presence of disturbing elements. Re-heating to a relatively low temperature will allow of a partial or complete return of the metal to its stable condition, i.e., with a normal content of graphite, hence the production of malleable graphitic iron from white cast-iron by annealing.

The author further discusses the changes taking place at the thermal critical points of steels, with respect to the nature of the structural constituents, and concludes that the four constituents formed during the cooling of steel are :—(1) A solid solution of carbon in γ-iron (austenite); (2) a solid solution of carbon in β-iron (martensite); (3) a solid solution of carbon in α-iron (troostite); and (4) the iron-iron carbide eutectoid (pearlite).

A method of calculating from the proportion of total carbon the percentages of the various constituents which should normally be present in iron-carbon alloys is given in an appendix, and also a table showing the proximate and ultimate compositions of alloys containing between 0·1 and 5 per cent. of carbon, both after solidification and after slow cooling.—A. S.

Steels; Determination of transformation points of —— by the method of electrical resistance. P. Fournel. Compt. rend., 1906, **143**, 46—49.

By an examination of the forms of the curves showing the alteration of electric resistance with temperature, the author has determined the transformation points in five steels to be as follows :—

	Steel No.				
	1.	2.	3.	4.	5.
Carbon ..	0·08	0·11	0·22	0·87	1·05
Silicon ..	0·24	0·03	0·22	0·126	?
Manganese	0·45	0·86	0·57	0·47	0·23
A_1	—	670°	685°		
A_2	775°	750°	730°	730°—770°	730°—750°
A_3	880°	880°	780°		

The resistance was measured on a wire, 0·3 mm. diameter, rolled round a double sheet of mica, and heated *in vacuo* by an electric resistance furnace. The wire was arranged in series with an ohm-meter, and a current of a few hundredths of an ampère passed through. The temperature was ascertained by a Le Chatelier pyrometer, the junction of which was inserted between the folds of the mica. Care was taken that the rates of heating and of cooling were the same for each series of measurements. —J. T. D.

Silver ores; The Francke-Tina process for the reduction of ——. A. Fox, jun. Proc. Inst. Civil Eng., 1905—1906, **163**, Part I.

The process is in operation in parts of Peru and Bolivia, but is so expensive in working that it can only be applied to rich ores. The ores at Caylloma consist of galena, copper pyrites, and iron pyrites, together with polybasite, pyrargyrite, and argentite, with a little blende and manganese blende, in a gangue of rhodonite and quartz. A general analysis shows:—Copper, 0·4 per cent.; iron, 3·0; lead, 0·9; zinc, 0·6; sulphur, 4·0; manganese oxide, 18·0; insoluble, 58·0; and alumina, &c., 6·0 per cent. The ore is hand-sorted at the mines into three classes: the first, about 7 per cent. of the whole, is shipped to England; the second, about 45 per cent., is sent to the San Ignacio Mill on muleback for treatment; the third, about 48 per cent., is at present thrown on the dump. At the mill the ore is dry crushed in a stamp battery; each stamp weighs 700 lb., gives 100 blows per minute, and crushes 0·6 ton per 24 hours through a 12-mesh screen, 76 per cent. of the product being fine enough to pass a 40-mesh screen. The crushed ore is roasted in 1200-lb. charges with 5 per cent. of salt in a 3-hearth reverberatory furnace for about 2½ hours on each hearth, by which 70 per cent. of the silver is converted into chloride. The fuel employed is either taquia (dried llama and alpaca dung), yareta (a resinous plant), wood, or coal. After furnacing, the ore is stirred up with water in a wooden tub or "tina" having copper or bronze fittings, small quantities of copper sulphate, lime, cyanide, and mercury being added; and the whole boiled up with steam. From time to time the amalgam formed is withdrawn, and the mercury is distilled off for further use.

The action in the tina is supposed to be as follows:—The silver chloride formed by roasting is dissolved in the salt solution, reduced by the copper, and taken up by the mercury; the consumption of copper is equal to more than 40 per cent. of the silver produced, which is much in excess of the theoretical quantity required. The extraction of silver by this process is about 70 per cent., of the little gold present only 50 per cent. The costs are:—For crushing, 8s. per ton; roasting, 19s.; amalgamating, 10s.; general, 3s.; total, 40s. per ton. The defects of the process as there carried out are thus specified by the author:—"The wet ore from the mines has to be dried; dry crushing is very slow; the dust loss is heavy; fuel for roasting is scarce and dear; salt is dear; there is a large amount of labour required; the repairs to the machinery are heavy; and water power for driving the mill is only available for six months in the year. Experiments in wet crushing and concentrating over tables so as to obtain a product rich enough for export, and treatment of the tailings by cyanide, have been somewhat successful."—J. H. C.

Copper; Power of —— to form alloys with pure iron and iron-carbon alloys. V. O. Pfeiffer. Metallurgie, 1906, **3**, 281. Chem.-Zeit., 1906, **30**, Rep., 210.

The author employed electrolytic copper and Swedish nail iron, using an electric furnace as the source of heat, by which temperatures of 1700° C. could be obtained. The metals were melted together in a magnesia crucible in an atmosphere of nitrogen. An addition of 0·5 to 35 per cent. of copper caused no alteration in the solidifying point of the iron; on adding more copper the point of solidification of copper became more distinct. There is no evidence of copper being soluble in iron or iron in copper to any appreciable extent, and also no evidence of the formation of mixed crystals of copper with either α- or γ-iron. Microscopic examination showed that the copper is only present in suspension in the solidified melt. Similarly in alloys containing 4 per cent. of carbon no solution took place, the copper remaining suspended in the fusion mixture. On allowing the liquid melt to stand, the copper collected at the bottom of the crucible.—E. F. A.

Mineral production of Quebec. Eng. and Mining J., July 7, 1906. [T.R.]

The report of J. Obalski, chief of the Bureau of Mines of Quebec, gives the following statement of the production of the Province in 1905. The quantities are in short tons of 2000 lb., except where otherwise noted:—

	Quantities.	Value.
		Dols.
Bog iron ore	12,878	35,266
Chromic iron ore	8,528	104,565
Copper ore	28,644	128,850
Asbestos	48,960	1,476,450
Asbestic	19,220	31,100
Mica (pounds)	378,560	95,460
Calcined ochre	1,905	22,675
Phosphate	1,475	8,875
Slates (squares)	4,900	21,568
Flag-stones (sq. yds.)	2,930	2,490
Cement	254,833	408,000
Granite	—	120,000
Lime (bush.)	1,000,000	140,000
Bricks	120,000,000	625,000
Stone	—	580,000
Totals	—	3,750,800

There were 5,017 men employed during the year, the wages paid amounting to $1,634,363, and the period of employment from five to 12 months. Two men were killed and two injured, the average of each being 0·4 per 1000 employees.

English Patents.

Metals and alloys; Production of fused ——, from oxides and other compounds. C. Vautin, London. Eng. Pat. 10,881, May 24, 1905.

It has been proposed previously to obtain metals from their compounds by mixing and igniting the latter with finely-divided metallic aluminium (see Eng. Pats. 6506 of 1894, and 16,685 of 1896; this J., 1895, 582; 1897, 742). According to the present invention the metal oxide, *e.g.*, iron oxide, or a mixture of metal oxides, in a dry solid state, is mixed with silicide or boride of magnesium or aluminium, and the mixture is ignited. The silicide or boride is converted into silicate or borate, which forms a slag, and the metal, *e.g.*, iron, is produced in a fused state. Claim is also made for the application of the process to the welding of metals.—A. S.

Iron or steel; Uniting or coating —— with other metals or alloys. G. L. Davies and W. G. Clark, Wessels Nek, Natal. Eng. Pat. 15,675, July 31, 1905.

The invention relates to the method of uniting or coating iron or steel with other metals, described in Eng. Pat. 17,660 of 1904 (this J., 1905, 1309), and consists in improvements whereby a plate of iron or steel can be coated on both sides simultaneously with copper, gold, or silver, or with an alloy containing one or more of these metals. Two furnaces are employed, one having a magnesite or other basic lining, in which the coating metal or alloy is maintained in the molten condition, whilst the other, in which the plate of iron or steel is heated, contains "a bath of molten flux composed of approximately equal quantities of silica and an alkali or

alkaline-earth carbonate." The heated plate is transferred to a highly heated mould of magnesite, clay, or foundry loam, and the molten coating metal run in.—A. S.

Steel; Method of and apparatus for manufacturing ——. F. André, Haardt bei Neustadt, Germany. Eng. Pat. 1356, Jan. 18, 1906.

See Fr. Pat. 362,371 of 1906; this J., 1906, 700.—T. F. B.

Steel; Manufacture of —— by the pneumatic process. A. Tropenas, Montelimar, France. Eng. Pat. 6484, March 17, 1906.

The molten pig iron or mixture of pig iron and scrap is blown as usual in the converter, but as soon as, or a very short time after, the "carbon flame" appears, a small quantity of ferro-silicon or iron high in silicon (varying according to the composition of the charge) is added. It is stated that by working in this manner, the evolution or progression of the "carbon flame" is not altered in any way, and thus the characteristic signs of this flame can be used for the stopping of the operation at the precise moment when the fining is finished.—A. S.

Gold; Treatment of complex ores containing ——. R. W. E. McIvor, M. Fradd, and The Metals Extraction Corporation, Ltd., London. Eng. Pat. 13,433, June 29, 1905.

The ores are roasted dead, ground, mixed in suitable proportions with a manganese ore containing manganese dioxide, and with magnesium chloride, and the mixture saturated with steam, whereby the gold is converted into chloride, and is afterwards recovered by known methods. —A. S.

Iridium; Art of producing metallic ——. H. H. Lake, London. From H. C. Parker, New York. Eng. Pat. 24,003, Nov. 21, 1905.

See U.S. Pat. 805,316 of 1905; this J., 1905, 1310.—T. F. B.

Tinned plates; The detinning of ——. K. Goldschmidt and J. Weber, Essen on Ruhr, Germany. Eng. Pat. 12,870, June 21, 1905.

See Fr. Pat. 356,228 of 1905; this J., 1905, 1311.—T. F. B.

United States Patents.

Precious metals; Process for recovering ——. J. A. Just, Pulaski, N.Y., Assignor to The Just Mining and Extraction Co., Syracuse, N.Y. U.S. Pat. 820,000, May 8, 1906.

The object of the invention is to extract gold and silver or other precious metals from ores, without previously chlorinating or roasting the latter. The claims are for the recovery of precious metals (gold and silver) from ores or material containing the same, by treatment with nitro-sulphonic acid, $HO.SO_2.NO_2$, to obtain the precious metals in solution, and precipitation of the metals in any suitable known manner. In practice, the best method of carrying out the invention is to treat the finely-ground ore with sulphuric acid along with sodium nitrate and atmospheric oxygen.—A. S.

[*Copper-nickel-manganese*] *Alloy* [*Electrical resistance*], W. B. Driver, East Orange, N.J. U.S. Pat. 824,103, June 26, 1906.

The alloy consists of copper, nickel (10—30 per cent.), and manganese (5—10 per cent.), practically free from iron or other foreign substances. One claim relates to an alloy containing 75 parts of copper, 20 parts of nickel, and 5 parts of manganese, for use as an electrical resistance material.—A. S.

Furnace; Roasting ——. F. Klepetko, New York. U.S. Pat. 824,181, June 26, 1906.

The furnace consists of a number of superposed hearths, through which a vertical hollow shaft passes. Hollow arms project from the shaft, and extend into the several hearths. The shaft and arms are divided into intercommunicating sections, and a body of water is caused to circulate through the central section and the arms corresponding therewith. The steam generated from the water is caused to circulate through the sections (and also through the corresponding arms) on either side of the central section.—A. S.

Furnace; Ore-roasting ——. C. H. Rider, St. Louis, Mo. U.S. Pat. 824,263, June 26, 1906.

The roasting chamber of the furnace has inlet and outlet doors in its front wall, and communicates at its rear end with a stack. A cylindrical retort is mounted in an inclined position in the roasting chamber, and can be rotated. There is an opening in one end of the retort, normally closed by a plate, and registering in turn, as the retort is rotated, with the openings in the wall of the roasting chamber. A feed-hopper is mounted above the inlet opening, and a discharge shoot below the outlet opening. The gaseous products from the retort are discharged into a dust chamber, from which they pass through a pipe to a condenser, and thence through another pipe to the stack.—A. S.

Furnace; Smelting ——. J. D. Rivard, Los Angeles, Cal. U.S. Pat. 824,383, June 26, 1906.

The furnace comprises an inclined chamber communicating at its upper end with a combustion chamber below. Liquid hydrocarbon fuel is supplied to the combustion chamber through injection burners, and air is supplied on each side of a central baffle-wall of chequer-work in the rear portion of the chamber. At the lower end of the inclined chamber is a stack, at the bottom of which is a "directing-chamber" containing a covered crucible. There is a reheating chamber in the top wall of the inclined chamber, communicating with the latter by means of ports. Pipes are also provided connecting the reheating chamber with a blower, and the blower with the stack. The ore is fed in at the upper end of the inclined chamber, and during its passage through this chamber, is subjected to action of a number of hot blasts of gas directed downwards upon it. Between the ore-feed opening and the stack is an opening through which material capable of producing carbon monoxide is introduced into the inclined chamber. The molten material flows out at the lower end into the crucible, whilst the products of combustion pass over the crucible, down through passages between the walls of the crucible and the sides of the "directing-chamber," and through ports in the walls of the latter, near the bottom, into the stack.—A. S.

Furnace; Reverberatory —— for the production of steel. V. Defays, Brussels. U.S. Pat. 825,522, July 10, 1906.

See Fr. Pat. 337,589 of 1903; this J., 1904, 493.—T. F. B.

Slag-granulating apparatus. E. B. Clark, Chicago, Ill. U.S. Pat. 824,340, June 26, 1906.

The apparatus comprises a tank which communicates at its lower part with an adjacent chamber of about the same height, and has a filter-bed near the bottom. The mixture of slag and water is fed into the tank, and passes through the filter-bed into the adjacent chamber. Means are provided for preventing the water in the tank from falling below a certain level above the filter-bed, these means consisting of a number of discharge-pipes at different heights in the adjacent chamber, the lowest pipe being above the level of the filter-bed.—A. S.

Ores; Process for the reduction of [*sulphide*] ——. W. Koehler, Cleveland, Ohio. U.S. Pat. 824,663, June 26, 1906.

Sulphide ores are heated, and subjected to the action of a gaseous mixture containing a halogen-acid, such as "anhydrous hydrochloric acid," and an oxidising agent, such as "anhydrous" nitric acid.—A. S.

Nickel from nickel carbonyl; Apparatus for obtaining ——. C. Langer, Clydach, Assignor to The Mond Nickel Co., Ltd., London. U.S. Pat. 825,844, July 10, 1906.

See Eng. Pat. 13,350 of 1905; this J., 1905, 1070.—T. F. B.

French Patents.

Silicon combined with calcium or its compounds; Thermal process based on the action of ——. T. Goldschmidt. First Addition, dated Jan. 10, 1906, to Fr. Pat. 361,197 of Dec. 30, 1905.

Instead of forming a thermite by compounding silicon and calcium with certain oxides, as directed in the main patent (this J., 1906, 593), according to the present addition, the silicon therein used is replaced by aluminium, with or without the addition of other reducing or non-reducing metals. Good results are stated to be obtained, for example, by using with a mixture of equal weights of aluminium and calcium, mixtures of equivalent proportions of calcium and of ferric oxide and of aluminium and ferric oxide. The calcium in the "thermite" may be replaced, partially or entirely, by strontium or barium. —E. S.

Pyritic ores containing zinc; Treatment of ——. The Metals Extraction Corporation, Ltd. Fr. Pat. 362,677, Jan. 25, 1906.

Pyritic ores containing zinc are roasted at a low red heat to oxidise as much as possible of the zinc sulphide to sulphate; the product is then lixiviated, and the solution of zinc sulphate obtained is treated with calcium chloride. The zinc chloride, freed from the precipitated calcium sulphate, is heated in an autoclave with the roasted and lixiviated ore, containing zinc oxide, which is dissolved. The solution of zinc oxychloride thus obtained is precipitated by chalk or caustic soda to obtain zinc carbonate or hydroxide. Alternatively, the pyritic zinc ore may be roasted at a high temperature, and be then treated in an autoclave with zinc chloride solution, to dissolve out of it the zinc oxide formed. Ores thus freed from zinc may be smelted, and treated by known processes to recover any lead, copper, silver, or other metals they may contain.—E. S.

Zinc and other metals; Continuous process for refining ——. J. Callmann and R. Bormann. Fr. Pat. 362,802, Jan. 29, 1906. Under Int. Conv., March 20, 1905.

See Eng. Pat. 3252 of 1906; this J., 1906, 481.—T. F. B.

Metals; Processes of extracting —— from their minerals, or from waste containing them. A. Gutensohn. Fr. Pat. 363,011, Feb. 6, 1906.

See Eng. Pat. 2619 of 1905; this J., 1906, 319.—T. F. B.

Minerals; Treatment of complex sulphide —— after oxidation, and of oxidised minerals containing zinc. W. G. Rumbold and G. Patchin. Fr. Pat. 363,025, Feb. 6, 1906. Under Int. Conv., Feb. 8, 1905.

See Eng. Pat. 2532 of 1905; this J., 1906, 325.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 701.)

(*A.*)—ELECTRO-CHEMISTRY.

Carborundum; Measurement of temperature in the formation of ——. S. A. Tucker and A. Lampen. J. Amer. Chem. Soc., 1906, **28**, 853—858.

On taking down an electric carborundum furnace built on the lines of a technical furnace, it was found that there were fairly sharp lines of demarcation between the layers of graphite, carborundum (crystallised silicon carbide), and siloxicon (amorphous silicon carbide). By placing through the centre of the furnace a horizontal graphite tube, containing a plug of graphite which could be pushed to any desired section of the furnace, it was found possible to measure, by aid of a Wanner pyrometer, the temperature of formation of carborundum, and also that of its decomposition into graphite and silicon. The results obtained for the temperature of formation, *i.e.*, the point where the amorphous siloxicon changes into the crystalline carborundum, were not quite so concordant as those for the temperature of decomposition, but the average results may be taken as follows:—Temperature of formation of carborundum, 1950° C.; temperature of decomposition of carborundum into graphite and silicon, 2220° C. —A. S.

Conductors of loosely-packed small pieces for electrical heating resistances. J. Brown. Electrotechn. Zeits., 1906, **27**, 213.

The corollary of Ohm's law that the resistance of a conductor is independent of the shape of its cross-section is not quite applicable in the case of granulated charcoal, or of "kryptol," which, according to recent statements, consists of mixtures of charcoal, graphite, sand, clay and other silicates, carborundum, tungstates, &c. It was found that with such discontinuous conductors, the heating phase is characterised by a preliminary diminution of the resistance. As this preliminary phase is caused by the disengagement of occluded gases, its extent can be considerably diminished by reducing the E.M.F. of the current, by applying the current gradually, and by increasing the exposed surface of the conductor, whilst it can be increased by the introduction of gases, or by addition of substances capable of evolving vapours. In apparatus where high temperatures are required, the renewal of the resistance mass from time to time cannot be avoided, and in such cases, it is advisable to employ a material having, as far as possible, a simple and uniform composition; otherwise, the more readily oxidisable or combustible constituents are consumed, and the composition and electrical properties of the resistance mass become subject to considerable variations.—A. S.

Nickel oxide electrode in the Jungner-Edison accumulator; Chemical and physical behaviour of the ——. J. Zedner. Z. Elektrochem., 1906, **12**, 463—473.

In continuation of his previous work (this J., 1905, 1239), the author has been led to the following conclusions:—In the charged condition the active material of the electrode consists of the hydroxide, $Ni(OH)_3$, and in the discharged condition, of the hydrated lower hydroxide, $Ni(OH)_2.2H_2O$. Since by its action water is removed, the E.M.F. is higher in dilute than in concentrated solution. The E.M.F. of the combination, $Ni(OH)_3/KOH/H$, for concentration above 24 per cent. of potassium hydroxide, may be calculated from the formula $E=1{\cdot}323-0{\cdot}1\gamma$ (where γ = the number of molecules of potassium hydroxide per molecule of water). The chemical reactions occurring during discharge and charge may be represented by the equation:—

$$Ni(OH)_3+2H_2O\rightleftarrows Ni(OH)_2.2H_2O+OH'+\oplus,$$

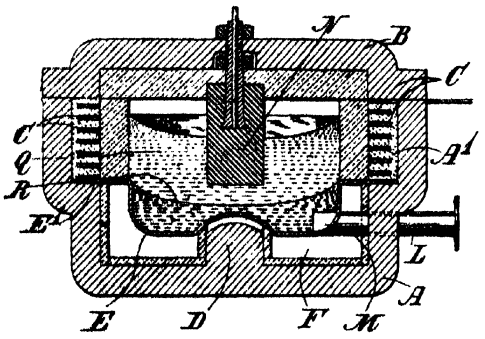
the discharge reaction being read from left to right, the charge from right to left. A study of the discharge curves leads to the conclusion that the first stage is due to the hydroxide, $Ni(OH)_3$, a second, much less well marked, step in the curve being ascribed to the discharge of occluded oxygen.—R. S. H.

Vanadium salts; Electrolytic preparation and properties of ——. L. Marino. Z. anorg. Chem., 1906, **50**, 49—52.

In the electrolytic reduction of vanadic to vanadous compounds the substitution of a mercury cathode for one of platinum, as proposed by Rutter (Z. Elektrochem., 1906, **12**, 230), is unnecessary. But it is essential to prevent the solution from becoming warm, and to avoid large excess of acid, especially hydrochloric acid. A solution of vanadyl sulphate containing 5—60 per cent., and an E.M.F. of 4—5 volts are suitable.

Silver sulphate, suggested by Rutter, cannot be used as a test for vanadous salts, since it is reduced by vanadic compounds also.—F. Sodn.

Cyanogen; Action of a silent electric discharge upon —— H. Gaudechon. Compt. rend., 1906, **143**, 117—119.



Pure, dry cyanogen, under the influence of the electric discharge, does not polymerise, but yields solid condensation products, with the elimination of nitrogen. They are brown soluble substances the composition of which varies with the conditions of formation.—F. Sodn.

Magnesium oxide; Physical properties of fused ——. H. M. Goodwin and R. D. Mailey. VII., page 757.

ENGLISH PATENTS.

Electrolytic cells [for fused substances]; Impts. in ——. E. A. Ashcroft, London. Eng. Pat. 5648, March 17, 1905.

THE outer casing, A, and lid, B, are of magnet steel, and within a recess, A^1, is arranged a coil, C, of heavy strip copper, this latter coil carrying the electric

current, and generating a magnetic field within the cell. The lines of magnetic force inside the cell spread in an axial or fan-like manner from the central pole, D, to the bottom of the lid, B, while outside the coil, C, they are conducted through the casing. In order that the magnetic effect of the coil may be varied, a commutator is connected with the several turns of the coil. A metal pan, E, forms the bottom of the cell, and is supported in the casing, A, by the flange, E^1, so that a flue space, F, is provided for the passage of furnace gases for heating purposes. L is an outlet and inlet pipe, divided into two parts by a partition, M. A fused electrode, R, is in contact with one terminal through the bottom of E, the flange, E^1, and the coil, C, the other electrode, N, of carbon, dipping into the fused electrolyte, Q. The lines of current flowing between N and R, are substantially axial or fan-like, and cut the lines of force approximately at right angles, thus causing the contents of the cell to swirl violently.—B. N.

Electrolytic solutions; Apparatus for agitating ——. F. J. Clarke, Birmingham. Eng. Pat. 17,152, Aug. 24, 1905.

THE apparatus consists of a system of pipes or passages arranged upon the bottom of the electrolytic vat, and provided at points above the floor level with discharge and "intake" perforations. An external pump is in connection with the perforated passages, but an intervening column or cushion of air completely isolates the pump from the electrolyte.—B. N.

Generator of electricity; Thermo-chemical ——. L. P. Basset, Epinay, France. Eng. Pat. 7375, March 27, 1906. Under Int. Conv., March 27, 1905.

THIS invention relates to a generator of electricity comprising two batteries in series, in one of which electric current is being generated by the solution of a metal, such as copper, in a suitable electrolyte, such as a solution of sulphuric acid and bromine. The second battery is traversed by the current generated, and also by the electrolyte. The latter when it leaves the generating battery contains the dissolved metal in solution, and a reducing agent such as sulphurous acid is then added. Copper is deposited on the cathodes of the second battery, as the electrolyte traverses the latter, until there is a sudden fall of E.M.F. in the first battery, whereupon the direction of the electrolyte is reversed through the two batteries. After the deposition of metal, the electrolyte consists of hydrobromic and sulphuric acids, but by passing it through an apparatus suitably heated, these acids may be made to interact so as to regenerate the bromine and sulphurous acid.—B. N.

Arc lamp electrodes; Impts. in ——. The British Thomson-Houston Co., Ltd. From Allgem. Elektricitäts Ges. Eng. Pat. 20,330, Oct. 9, 1905. II., page 747.

Nitric acid; [Electrical] Production of pure —— *[from air]*. H. Pauling. Eng. Pat. 7871, April 2, 1906. VII., page 758.

UNITED STATES PATENT.

[Copper-nickel-manganese] Alloy [Electrical resistance]. W. B. Driver. U.S. Pat. 824,103, June 26, 1906. X., page 764.

FRENCH PATENTS.

Accumulators; Manufacture of plates for ——. E. de Marçay. Fr. Pat. 362,909, Jan. 24, 1906.

A MIXTURE of aluminium chloride and litharge is made by mechanical means, a solution of sodium carbonate being then added, and the whole kneaded together. The mass is incorporated within a framework of lead, and left to solidify. The aluminium salt and sodium carbonate react, with formation of aluminium hydroxide and sodium chloride and disengagement of carbon dioxide. The salt is removed by washing with water, and the hydroxide is converted into aluminium sulphate by immersion in dilute sulphuric acid, the aluminium salt being afterwards removed by lixiviation. By the action of the electric current a skeleton of lead peroxide or of spongy lead may be obtained, solidly fixed to the framework, the plates having great surface, large capacity owing to the great porosity, and a great mechanical resistance to shocks. —B. N.

Sugar juice; [Electrolytic] Method of clarifying ——. R. J. Thomas and W. F. S. Howe. Addition, dated Jan. 5, 1906, to Fr. Pat. 353,568, April 20, 1905. XVI., page 771.

Salts of the oxy-halogen acids; Electrolytic production of ——. Deutsche Solvay-Werke A.-G. Fr. Pat. 362,737, Jan. 10, 1906.

SOLUBLE salts of vanadium, manganese, molybdenum, or uranium are added to the electrolyte employed for the production of the salts of the oxy-halogen acids with a view to suppressing the cathodic reduction and consequent loss of efficiency. Details of experimental results are given to show the effect of these several additions.—R. S. H.

(*B.*)—ELECTRO-METALLURGY.

Steel; Electrolytic corrosion of structural ——. M. Toch. Trans. Amer. Electrochem. Soc., May 1, 1906. Electrochem. and Metall. Ind., 1906, **4**, 215—216.

THE author has carried out experiments with strips of steel embedded in sand and cement moistened with salt solutions, and submitted to electrolysis. He concludes that electrolytic corrosion under these conditions is confined to the anode where it takes place with violence, the cathode being protected by the electric current. The impression that cement is a protector against corrosion is fallacious. If the steel be protected with a real insulating material corrosion can be entirely prevented.—R. S. H.

ENGLISH PATENT.

Shaft-furnaces; Impts. in electrically heated ——. Allmänna Svenska Elektriska Aktiebolaget, Westeras, Sweden. Eng. Pat. 7597, March 29, 1906. Under Int. Conv., March 30, 1905.

THE furnace is provided with a hearth forming an annular chamber of uniform or substantially uniform cross-section for taking up the melted material. In the hearth is a central hollow core of fireproof material, a hollow

extension of the core extending upwards through the centre of the shaft, thus producing an in-draught of cold air into the hollow core. In the latter is placed an iron core provided with a primary winding, and the e is thus produced in the melted mass a secondary current which heats the material.—B. N.

United States Patent.

Metal tubes; Electrolytic manufacture of ——. O. Dieffenbach, Darmstadt, Germany. U.S. Pat. 817,419, April 10, 1906.

"Comminuted kieselguhr" is mixed with a suitable electrolyte, and an electric current is passed through the mixture, whilst simultaneously a relative motion is produced between the electrolyte and the rotating cathode. The hydrogen bubbles are thus dislodged, and the metallic deposit is smoothed by the action of the kieselguhr.—B. N.

French Patents.

Metalliferous minerals; Electrolyser for treatment of — —. E. T. de Montrépeux. Fr. Pat. 362,680, Jan. 25, 1906.

A cylindrical wooden vat provided with mechanism for its rotation serves as the electrolysis vessel. The vat is provided internally with longitudinal rows of carbon electrodes, forming alternately anodes and cathodes. The heads of the electrodes pass through the walls of the vat, and on the outside are fixed to connectors, enabling them to be placed suitably in series. The current is collected from metallic strips which make contact with bands of metal forming the terminals.—R. S. H.

Electric furnace for the manufacture of steel. G. Gin. Fr. Pat. 362,734, Jan. 26, 1906. Under Int. Conv., May 3, 1905.

The furnace is divided into three compartments which communicate with one another in series, and serve respectively for the refining of the crude metal by oxidation, for the reduction of dissolved oxide, and for the carburisation, and finally for the adjustment of the composition of the finished metal. The electric current passes through vertical carbon electrodes dipping into the slag above the metal in the different compartments, and the connections are made so that whilst all the current passes in through the compartment reserved for refining, it passes out in parallel through the other two compartments. Means are provided for tilting the furnace in order to pour out the finished product (this J., 1905, 1115).—R. S. H.

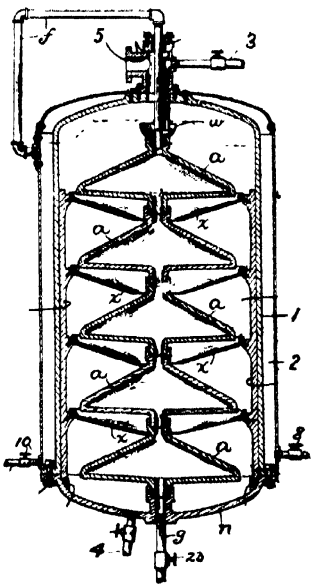
Electrotypes, Process and apparatus for making copper ——. S. O. Cowper-Coles. Fr. Pat. 362,861, Jan. 30, 1906. Under Int. Conv., March 6, 1905.

See Eng. Pat. 4668 of 1905; this J., 1906, 322.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 702.)

Cholesterol. A. Windaus. XXIV., page 780.



English Patent.

Oils, fats, or the like, Manufacture of viscid or fluid emulsions of — —*[for lubrication of textile fibres].* O. A. H. H. Kösters, Hemelingen, Germany. Eng. Pat. 4688, Feb. 26, 1906.

Emulsions containing any required proportion of water, and remaining stable at the boiling point of water, and also when mixed with glycerol, are obtained by adding the fat or oil, *e.g.*, heavy cylinder oil, to a mixture of water and an amide of a higher fatty acid or an acidyl derivative of an aromatic base, or both, together with the salt of a higher fatty acid. The emulsion may then be mixed with glycerol or other substance capable of raising the specific gravity of water, *e.g.*, for the preparation of lubricants for textile fibres.—C. A. M.

United States Patents.

Naphtha, &c.; Apparatus for separating ——, *from oil and other liquids.* E. R. Edson, Cleveland, Ohio. U.S. Pat. 824,104, June 26, 1906.

The apparatus consists of a casing, 1, (surrounded by a jacket, 2) containing a number of conical, communicating heating-drums, *a*, arranged one above the other. The liquid to be treated enters the apparatus by the pipe, 3, and flows into the cup, *w*, from which it overflows on to the upper surface of the topmost drum, *a*. From the edge of the lower surface of the latter, it flows into the funnel, *x*, and is conducted to the top of the cone of the next drum, and so on to the bottom, where the residual liquid from which the naphtha has now been expelled, collects in the basin, *n*, and is drawn off by the drain, 4. The vapours of naphtha, &c., given off pass away to a condenser by the elbow-pipe, 5. Steam enters the jacket by the pipe, 8, passes round, and leaves by the pipe, *f*, which conducts it to the interior of the uppermost heating drum, *a*, from which it passes down from drum to drum, the condensed water being drawn off through the pipe, *g*, and the valve, 23. Any water condensing in the jacket is drawn off through the valve, 10.—W. H. C.

Soap; Apparatus for making ——. T. W. Alexander and E. F. Holsteen, Burlington, Iowa. U.S. Pat. 824,167, June 26, 1906.

Claim is made for a mould-frame which can be locked upon a support by means of co-operating jointed rods, one joint of each of which passes through slots in the support, whilst the other joints interlock across the top of the frame. The soap mould may also be provided with a steaming jacket, the inner walls of which are perforated.—C. A. M.

German Patent

Fatty compounds; Process for preparing easily emulsified, stable ——. Ges. zur Verwerthung der Bolegschen wasserlöslichen Mineralöle und Kohlenwasserstoffe. Ger. Pat. 167,847, May 27, 1904.

Animal and vegetable oils, fats, and waxes are converted into stable, readily emulsified preparations, by treating

them, at a temperature between 60° and 80° C., with the water-soluble mineral oils produced according to Fr. Pat 332,324 of 1903 (this J., 1903, 1289).—T. F. B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*Continued from page* 704.)

(*A.*)—PIGMENTS, PAINTS.

Paints; Census of —— in the United States. Oil, Paint, and Drug Rep., July 9, 1906. [T.R.]

The Director of the Census has announced the result of the tabulation of the statistics of paints for the calendar year ending December 31, 1904. The statistics show that there has been a substantial increase in this industry in the United States, as compared with the statistics of 1900, which covered the fiscal year ending May 31.

Comparative figures for 1905 and 1900 are shown in the following summary:

		1905.	1900.	Per cent. of inc.

English Patents.

Antimony and arsenic colours; Manufacture of ——. L. Brunet, Brioude, France. Eng. Pat. 16,490, Aug. 14, 1905. Under Int. Conv., April 15, 1905.

The process claimed consists in treating the sulphantimonates or sulpharsenates of alkalis or alkaline-earths dissolved in suitable solvents with the gas evolved when any suitable sulphide producing sulphurous gas is roasted, until the solution becomes acid. The advantages are stated to be cheapness and avoidance of the inconvenient yield of hydrogen sulphide in the ordinary process. Moreover the residue, instead of being valueless, is a solution of alkali thiosulphate, which can be used in the manufacture of vermilion of antimony.—C. A. M.

Lithopone; Rendering —— more stable against light. J. Ephraim, Berlin. Eng. Pat. 7819, March 31, 1906. Under Int. Conv., April 1, 1905.

The lithopone is treated with a non-acid salt capable of precipitating zinc from solutions of its salts. Sodium and potassium salts are particularly suitable for the purpose, and special claim is made for the addition of alkali phosphates. The salts may either be added, say, in the proportion of 1 to 3 per cent. to the lithopone, and the mixture used as a pigment, or they may be incorporated in the form of a solution, and the solvent evaporated, or they may be allowed to act for a certain time, and then separated by lixiviation with water.

—C. A. M.

Colour bases; Products soluble in water, fats, and oils from the salts which higher fatty acids and acids of the oleic series form with organic ——. Farbw. vorm. Meister, Lucius, und Bruning, Hoechst a/Main, Germany. Eng. Pat. 10,079, April 30, 1906. Under Int. Conv., May 19, 1905.

The salts of the higher fatty acids and acids of the oleic series with organic dyestuff bases are used for colouring fats and oils. They are insoluble in water. The present process is for the preparation of colours soluble in water as well as in fats and oils by mixing the above salts with an aqueous solution of an alkali salt of a benzylaniline-sulphonic acid or homologue thereof.—H. L.

(*B.*)—RESINS, VARNISHES.

United States Patent.

Turpentine still. D. M. Ross and F. T. Edwards, Fletcher, Ga. U.S. Pat. 821,887, May 29, 1906.

The plant described consists of two kilns or stills, the outlet pipe of each leading into a common cylindrical drum, where the bulk of the creosote and tarry matters are separated from the volatile products. This drum is provided with an external water spray and an internal supply of water for washing the vapours. The latter then pass through a pipe into a purifier containing a baffle-plate, and from this purifier into a worm condenser. The outlet of the condenser is fitted with a trap, and any uncondensed gases are conducted back to the kilns, where they are consumed. Openings are provided at the bottoms of the various parts of the plant for the removal of the condensed matters.—W. P. S.

French Patent.

Tubes; Process for producing a protecting layer [varnish] on the interior surface of ——. Deutsch-Oesterreichische Mannesmannrohren-Werke. Fr. Pat. 362,886, Jan. 31, 1906.

The interior surface of the tube is covered with a thin coat of special varnish, about 0·1 mm. thick. The varnish is prepared by dissolving gum dammar in oil of turpentine, and adding 75 per cent. of linseed oil; the mixture is heated for some time to above 100° C., and then cooled, when it forms a varnish which is liquid at the ordinary temperature. The interior surface of the tube is coated with this mixture, and the coat at once dried by passing a current of air, heated to at least 140° C., through the tube. The drying takes from two to four hours, and owing to the speed of this drying, the layer of varnish has no time to run, but forms an even, thin, hard, adherent layer which is extremely resistant, and which does not melt below 260° C.—W. N. C.

(C.)—INDIA-RUBBER, &c.

Rubbers; Examination of some raw —— from East Africa. W. Schellmann. Der. Pflanzer, 1906, **2**, 1—6. Chem. Centr., 1906, **1**, 1911—1912.

In judging the value of raw rubber, the chief points are determinations of the loss on washing—that is, the proportion of substances which are removed by the ordinary technical washing process—and the ratio of pure caoutchouc to substances other than caoutchouc, especially resin, in the washed product. In six samples of rubber from East Africa the loss on washing varied between 20 and 40 per cent., and the percentage of pure caoutchouc between 47·32 and 65·90 per cent. The ratio of pure caoutchouc to resin ranged from 93·35 : 6·65 to 87·95 : 12·05. These samples of raw rubber were of good quality, in so far that they were capable of yielding technically useful rubber, but their commercial value was diminished by their content of substances other than caoutchouc and resin. The view is put forward that it would be advantageous to subject raw rubbers to mechanical purification before exporting them.—A. S.

Caoutchouc; Theory of the vulcanisation of ——, in the light of Harries' formula for caoutchouc. R. Ditmar. Gummi-Zeit., 1906, **20**, 1026—1028.

The author recapitulates the main facts regarding the vulcanisation of caoutchouc elucidated by Weber (this J., 1902, 712) and others, and shows how they can be made to agree with the dimethyl-octadiene formula of Harries (this J., 1905, 449).—W. A. C.

India rubber. Vulcanisation of —— in presence of resin. R. Ditmar. Gummi-Zeit., 1906, **20**, 999—1000.

Para rubber containing 3·28 per cent. of resin was mixed with 10 per cent. of sulphur and rising proportions of resin which had been extracted from fine black Upper Congo, and vulcanised for 45 minutes at 145° C. under 4—5 atmospheres pressure. With increasing proportions of resin, the breaking strains of the vulcanised specimens decreased very decidedly. The elongations increased slightly, but not in proportion to the elasticity of the specimens, since these showed a tendency to become soft, especially with 18 per cent. and upwards of added resin. It is proved experimentally that the higher the resin-content, the greater the proneness to atmospheric oxidation.—W. A. C.

Rubber production in Assam and Burma. Bd. of Trade J., July 26, 1906. [T.R.]

The following statement, showing the quantity of rubber extracted by the Forest Department from plantations of *Ficus Elastica* in Assam and of *Hevea Brazilensis* in Burma and the average prices obtained, is taken from the "India Trade Journal".

Year	Assam		Burma (Tenasserim).	
	Quantity lb.	Average price per lb	Quantity lb.	Average price per lb
		s d		s d
1903-04	9,387	3 8	864	4 9
1904-05	12,368	3 7	1,450	5 8
1905-06	14,010	4 0	Not stated	

Grants or leases of waste land not exceeding 1200 acres in area for the purpose of planting rubber trees may be made by the Deputy Commissioner, with the previous sanction of the Commissioner, in any district of the Tenasserim Division, and in any other district specially notified by the Local Government. When the area which it is proposed to grant or lease, exceeds 1200 acres, the application shall, with the recommendations of the Deputy Commissioner and Commissioner, be submitted to the Financial Commissioner for his orders.

United States Patents.

Gum [rubber]; Process of obtaining —— from vegetable matter. E. Heber, New York. U.S. Pat. 824,116, June 26, 1905.

The disintegrated wood or other material is heated in a suitable vessel at ordinary or increased pressure with a solution of soap, with or without the addition of suitable solvents, such as benzol, rosin oil, &c., until the gum (*e.g.* caoutchouc, gutta-percha, or chicle) is dissolved or emulsified. Other constituents can then be separated, and the gum precipitated.—C. A. M.

Rubber waste; Process for reclaiming vulcanised ——. A. Kittel, Vienna. U.S. Pat. 825,060, July 3, 1906.

See Fr. Pat. 344,734 of 1904; this J., 1904, 1226.—T. F. B.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 705.)

Glue; Determination of the gelatinisation temperature and specific gravity of different solutions of ——. K. Wenkülblech. Z. angew. Chem., 1906, **19**, 1260—1262.

The best method of determining the melting point of a solution of glue ought to be that of stirring a large quantity of the jelly with the liquid part until it was liquefied, and noting the point at which a sudden rise of temperature occurred, but experiments with 10 per cent. solutions showed that the method was not practicable, the temperature rising before the end of the solid stage. On the other hand, serviceable results are obtained by determining the temperature of gelatinisation. For this purpose the weighed quantity of glue is allowed to soak overnight in cold water, and then dissolved in water at 40° to 50° C., and the solution made up to 500 c.c. at 40° C. It is advisable to use a large quantity of solution for the determination (about 400 c.c.), and the bulb of the thermometer should be about in the middle of the flask, which should be cooled with continual shaking and stirring. Gelatinisation occurs quite suddenly, but in the case of dilute solutions, *e.g.*, 2 per cent., care is necessary in observing the end-point, since such solutions may easily be cooled below the gelatinisation temperature. In the author's experiments the determinations of the specific gravity of the solutions were made with a hydrometer, and confirmed by weighing. The following comparative results were obtained with different samples of glue and with Merck's animal glutin:—

Solution of glue, &c.	Grms. per litre	Specific gravity at 50° C.	Specific gravity at 40° C.	Specific gravity at 30° C.	Specific gravity at 25° C.	Gelatinisation temperature. °C.	Sp. gr. at gelatinisation temperature.

Old solutions of gelatin kept in a cool room for several days (20 to 37) showed a marked decrease in the gelatinisation temperature without any pronounced change in the specific gravity. Partial purification of glue from soluble salts by extraction with cold water caused a considerable rise in the gelatinisation temperature, the effect of distilled water being much greater than that of tap water. As to the amount of colloid dissolved by the cold water, much more gelatin was taken up than in the case of joiners' glue, whilst remarkably little of the Russian glue passed into solution, this being attributed to the large amount of filling material. Large quantities of chemically indifferent substances, such as glycerol and cane sugar, can be present without interfering greatly with the gelatinisation temperature. The difference between the gelatinisation temperatures of solutions of equal strength of a glue and a good gelatin becomes greater on dilution in the case of impure glues, whilst with purer samples it remains approximately constant. The average differences observed were 7·5° C. for a good glue, 12·5° C. for Mulhouse glue, and 15° C. for Russian I. glue.
—C. A. M.

Gelatin; Action of alums and aluminium salts on ——. A. and L. Lumière. Brit. J. Phot., 1906, **53**, 573—574.

Besides aluminium sulphate and potassium and ammonium alums, it is found that alumina, and aluminium chloride, bromide, and nitrate all have a similar action in raising the solidifying point of a solution of gelatin. The alkali aluminates have no effect on the solidifying points. For the other compounds above mentioned, an increase in their amount raises the solidifying point of the gelatin solution, until a maximum is reached, corresponding in all cases, for a given strength of gelatin solution, to a definite weight of alumina: thus, 0·04 grm. of alumina or 1·6 grms. of aluminium chloride produces the maximum effect on 100 grms. of a 7·5 per cent. gelatin solution. The treatment of gelatin with solutions of aluminium salts appears to result, at first, in the absorption of the salt as such, the subsequent washing with water dissociating the salt into the acid and alumina, the latter remaining combined with the gelatin. The quantity of alumina combined with the gelatin increases with the weight of salt employed, until 3·6 per cent. of alumina is combined; beyond that point there is no increase.—T.F.B.

English Patents.

Leather; Process for producing artificial ——. H. Karle, Seckenheim, Germany. Eng. Pat. 26,517, Dec. 19, 1905.

See Addition of Nov. 17, 1905, to Fr. Pat. 342,622 of 1904; this J., 1906, 488.—T. F. B.

Catgut threads; Process of sterilising ——. H. Schmidt, Mannheim, Germany. Eng. Pat. 7825, March 31, 1906. Under Int. Conv., April 4, 1905.

The threads are immersed in an aqueous solution containing 1 per cent. each of iodine and potassium iodide, and from 0·4 to 0·5 per cent. of 40 per cent. formaldehyde solution, 1 per cent. of glycerol being also added, if desired. After being in this solution for eight days, the threads are ready for immediate use, or they may be dried, and kept in suitable sterilised envelopes.—W. P. S.

Casein compounds; Manufacture of films or sheets from ——. F. Thomas, Cologne, Germany. Eng. Pat. 18,328, Sept. 11, 1905.

Films or sheets prepared from solutions of casein in alkali are not impermeable to moisture; those prepared from solutions in dilute acid, however, are free from this defect. 100 grms. of casein may be dissolved by heating in a litre of water containing 8 grms. of 25 per cent. hydrochloric acid; 10 grms. of 40 per cent. formaldehyde solution and a small quantity of glycerin are added, and the solution is poured on glass plates to dry.—T. F. B.

French Patents.

Tannin extracts; Process for the decolorisation of ——. Soc. Badische Anilin und Soda Fabrik. Fr. Pat. 362,780, Jan. 27, 1906. Under Int. Conv., Jan. 5, 1906.

The extracts are decolorised by treatment with a formaldehyde-sulphoxylate, either pure, or mixed with a formaldehyde-bisulphite. For example, 1 litre of chestnut extract of 4° B. is treated with about 5 grms. of Rongalite C. (sodium-formaldehyde sulphoxylate of about 90 per cent. strength), and evaporated to dryness in a vacuum.
—A. S.

Hides and skins; Process and apparatus for tanning and depilating ——. C. J. Glasel. Fr. Pat. 362,663, Jan. 24, 1906.

The skins are treated with the tanning or depilating substance, meanwhile being alternately stretched and slackened, so as to expel spent material from the pores, and cause a fresh quantity to be taken up. The machine claimed for this purpose has a tank, preferably rotating, provided with means for causing the tanning or depilating substance to circulate, together with internal supports to which the skins can be attached, and means for making the skins become tight or slack intermittently.—C. A. M.

XV.—MANURES, &c.

Nitrogen-assimilating bacteria; Researches on anaërobic ——. E. Haselhoff and G. Bredemann. Landw. Jahrb., 1906, **35**, 381; Chem.-Zeit., 1906, **30**, Rep., 223.

Anaërobic nitrogen-assimilating bacteria (*Clostridia*) are abundantly met with in soil and on the leaves of forest trees. The amount of nitrogen assimilated from the atmosphere by these organisms is approximately equal to that found by Wingogradsky in the case of *Clostridium Pasteurianum*, being 2·74 mgrms. per grm. of dextrose or mannitol, as compared with a maximum of 3 mgrms. found by that author.—C. S.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 707.)

Rhamnose; Alkylation of ——. T. Purdie and C. R. Young. Chem. Soc. Proc., 1906, **22**, 201.

By complete methylation with silver oxide and methyl iodide, acetone- and methyl-rhamnosides yield respectively *dimethylacetone-rhamnoside* and *trimethylmethyl-rhamnoside*, and by hydrolysing these compounds, *di-* and *tri-methylrhamnose* respectively are obtained. The rhamnose derivatives described are liquids, but all of them excepting dimethyl-rhamnose being volatile without decomposition, it was possible to isolate them by fractional distillation under reduced pressure.

Dimethyl- and trimethyl-rhamnose give crystalline phenylhydrazones, and display the ordinary properties of reducing sugars. Trimethyl-rhamnose is re-converted into trimethylmethyl-rhamnoside by condensation with methyl alcohol, and also by the silver oxide method of alkylation; the former process gives mainly the α-form of the aldoside, the latter a mixture composed largely of the β-form. The presence of the β-isomeride was recognised not only by its rotatory power, but also by the rapidity of its hydrolysis. The rotatory powers of the substances described fall into line with those of dextrose and its corresponding derivatives.

l-Arabinose; Alkylation of ——. T. Purdie and R. E. Rose. Chem. Soc. Proc., 1906, **22**, 201—202.

By methylating Fischer's α-methylarabinoside with silver oxide and methyl iodide, *trimethyl-α-methylarabinoside* is obtained in large, well-formed crystals (m. pt., 43°—45°), and by hydrolysing this with dilute hydrochloric acid, *trimethylarabinose* is produced. This substance is a liquid (b. pt., 148°—152° C. at 19 mm.), but otherwise it

exhibits the usual properties of a reducing sugar. It can be methylated by condensation with methyl alcohol, and also by treatment with methyl iodide and silver oxide, the product in both cases being a mixture of the isomeric trimethylmethylarabinosides. The condensation process yields the crystalline α-isomeride in large proportion, the silver oxide process mainly the β-isomeride. The latter substance is apparently a liquid, and it could not be isolated, but its presence in the mixture was recognised by its undergoing hydrolysis more rapidly than the isomeric α-form. In preparing Fischer's α-methylarabinoside, a small quantity of the *β-methylarabinoside* was obtained in crystalline prisms melting at 115°—117° C. With respect to rotatory power, the isomeric methylarabinosides and trimethylmethylarabinosides show relations similar to those of the corresponding derivatives of dextrose.

Starch; Behaviour of —— on hydrolysis with moderately strong sulphuric acid. B. Tollens. Z. Ver. deutsch. Zuckerind., 1906, 664—669.

Some mosses, such as reindeer moss, require to be heated for 10—12 hours with 6—7 per cent. sulphuric acid in order to ensure their complete hydrolysis. Others, such as Iceland moss, are readily hydrolysed when heated for 5—6 hours with 5—6 per cent. sulphuric acid. The former mosses on hydrolysis yield considerable quantities of *d*-mannose and *d*-galactose, besides a little dextrose. The latter mosses, on the other hand, furnish dextrose chiefly, and only small quantities of the other sugars. The author has investigated the question whether the mannose and galactose produced in the former case are actually hydrolytic decomposition products, or whether they are produced from originally formed dextrose by the prolonged hydrolysis with strong acid. 320 grms. of potato starch were made into a paste with some water, and the whole poured into a mixture of 2000 grms. of water and 160 grms. of pure, concentrated sulphuric acid. The mixture (containing 6—7 per cent. of sulphuric acid) was liquefied in a dish on the water-bath, and then heated in a boiling water-bath for 10 hours. The hydrolysed solution was found to contain a large quantity of dextrose and some by-products, chiefly of an amorphous nature, but no galactose, and at the most only traces of mannose. From these results the author concludes that the mannose and galactose, obtained by the hydrolysis of reindeer moss, originate, not from the conversion of dextrose during hydrolysis, but from the hydrolysis of the hemicelluloses, *i.e.*, mannan and galactan, contained in the moss.—L. E.

United States Patent.

Sugars; Process of converting cellulose of wood into fermentable ——. A. Classen, Aachen, Germany, Assignor to Classen-Lignum Co., New Jersey. U.S. Pat. 825,808, July 10, 1906.

See Ger. Pat. 161,644 of 1904; this J., 1905, 1078.—T.F.B.

French Patents.

Sugar juice; [Electrolytic] Method of clarifying ——. R. J. Thomas and W. F. S. Howe. Addition, dated Jan. 5, 1906, to Fr. Pat. 353,568, April 20, 1905 (this J., 1905, 1024).

The sugar juice is heated in a suitable vat or reservoir to near its boiling point, and is submitted to electrolysis, which produces rapid and almost complete clarification. —T. H. P.

Liquids which are not easily filtered, such as milk of lime, and diffusion juice [from beet sugar factories]; Apparatus for purifying ——. H. Korán. Fr. Pat. 362,646, Jan. 23, 1906. VII., page 750.

Diffusion process [for beetroot sugar works]. L. E. Rousseau, A. Guidet, and J. H. Sahut. Fr. Pat. 362,857, Jan. 30, 1906.

Each diffuser of a battery is provided with two pipes, one entering at the top of the apparatus and the other at the bottom. The former is in connection with an exhaust-pump, and when the pressure has been reduced to about 300 mm., steam is admitted through the lower pipe until the desired temperature in the diffuser has been attained. Taps fitted on both pipes are then turned off, and the diffusion allowed to proceed as usual.—W. P. S.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 710.

Pediococcus viscosus, the cause of mucilage formation in "Weissbier." F. Schönfeld. Jahrb. Ver. Versuchs- u. Lehranstalt f. Brau., Berlin, 1905, 8, 90; Z. ges. Brauw., 1906, 29, 427—428.

Pediococcus viscosus causes mucilage formation most abundantly in wort which has not been heated above 75° C., to a less extent in boiled wort, and least in a boiled, hopped wort. Mucilage is formed more readily in wort from grain poor in albumin than in wort from grain rich in albumin; the reverse is the case with beer. A 10 per cent. solution of cane sugar containing 0·1—0·5 per cent. of asparagine or peptone, is rendered mucilaginous by the organism. A 50 per cent. sugar solution treated with 0·5 per cent. of peptone and with potassium or magnesium sulphate, forms mucilage with the *Pediococcus*. The degree of mucilage formation decreases with increasing sugar concentration. No relation exists between the development of the organism and the amount of mucilage produced. Cane sugar solution containing no nitrogenous organic matter does not become mucilaginous. The organism forms a mucilaginous deposit in ammoniacal sugar-yeast water; a similar deposit is obtained in solutions of dextrose, lævulose, invert sugar, maltose, lactose, dextrin, and potato and wheat starches (with addition of yeast water). The organism acts on pasteurised and on bottom-fermentation beer in the same way. Completely fermented beer is very resistant to the *Pediococcus*; mucilage is formed at once, however, if the beer is subjected to an after-fermentation by addition of sugar. Mucilage is generally produced most abundantly if much sugar and living yeast cells are present. Heating for one hour at 44° C. decomposes the mucilage, and kills the *Pediococcus*; in the first stage of growth, however, the organism is not killed by heating for two hours at 44° C., nor does it lose its power of forming mucilage. The organism lives for a very long time in beer. Development of the organism and mucilage formation are considerably retarded by vigorous aëration of the culture medium. The *Pediococcus* is incapable of causing fermentation with evolution of gas.

The formation of mucilage is probably due:—(*a*) to reversion of sugar, (*b*) to decomposition of albumin. Both processes, however, go on simultaneously, the production of mucilage being chiefly due to the former. —L. E.

Cider yeasts; Contribution to the knowledge of ——. A. Osterwalder. Wochensch. f. Brau., 1906, 23, 376.

The author has investigated a large number of yeasts isolated from cider and perry. Earlier work had shown that grape wine yeasts for the most part belong to the *S. ellipsoideus* group, whilst cider yeasts in the majority of cases are *S. pastorianus* varieties. Of twelve cider yeast cultures, two only were *S. ellipsoideus* yeasts, the remainder being *S. pastorianus* yeasts. In the sediment the elliptic cell-forms of the *pastorianus* yeasts exceeded the cylindrical cell-forms in number; the latter disappeared entirely or nearly so, on cultivation in Sicilian grape juice. A few of the yeasts formed spores on gypsum blocks in 15 hours; in the case of a few varieties, spores were formed in four days from 70—80 per cent. of the cells; some varieties did not sporulate.—L. E.

Vinasse; Treatment of —— at the Raab spirit factory. J. Ginsberg. Oesterr. Brenn.-Zeit., 1905, 187; Z. Spiritusind., 1906, 29, 255.

From 120 to 140 metric tons of molasses are treated daily, and yield about 2300 hl. of residue, which is concentrated, carbonised, and worked up into potash salts. The neutralised residue is passed through three evaporators: one with a heating surface of 180 sq. m., heated by steam,

whilst the other two are smaller, and are raised by waste heat to a temperature of 80°—90° C. and 60°—70° C. respectively, the evaporation being effected in a partial vacuum. On leaving these, the residue is concentrated from 20°—22° B. to 40° B. strength, and is next carbonised in two ovens, without any added fuel, the heat liberated being utilised for steam raising. From the ovens the mass is discharged into a shaft, where it is left to smoulder awhile in small trucks, which are emptied on to a floor where the heaped-up mass burns away to ash. The latter contains 0·5—5·4 per cent. of water, 56—58 per cent. of potassium carbonate, 10—12 per cent. of sodium carbonate, 8—10 per cent. of potassium sulphate, 0·3—0·4 per cent. of sodium sulphate, 6—7 per cent. of potassium chloride, 0·4—0·6 per cent. of potassium phosphate, 10—11 per cent. of insoluble matter, and 1·0—1·5 per cent. of organic substances. It is reduced to powder in ball-mills, and then lixiviated with hot dilute lye. The resulting solution is concentrated to 46°—47° B. strength in a vacuum pan, the potassium sulphate crystallising out in the warm, and the potassium chloride on cooling the mother liquor to 25°—30° C. The residual liquor is further concentrated to 50°—53° B., and throws down a double carbonate of sodium and potassium, from which the potassium salt is dissolved by treatment with soda lye. On further cooling, the mother liquor deposits in succession impure potassium chloride and another crop of the double salt, which latter is treated as before; and on repeated concentration and cooling, furnishes a 95 per cent. potash. —C. S.

German Customs Union; Trade in the —— in 1905. Z. Spiritusind., 1906, **29**, 257.

	Imports.		Exports.

The unit prices (per 100 kilos.) of imported potato and rice starch and crystallised starch sugar; also those of the last named, potato starch, and vinegar, for export, were estimated on the same basis as in 1904. On the other hand, a reduction in price occurred in dextrin, starch, spirits, acetic acid, wines, and wood spirit for importation; and in spirits, yeast, vinegar, and wood spirit for export. In all others an increase is recorded.—C. S.

Spirit trade; Russian export ——. Weschtsch. Finanzow. Z. Spiritusind., 1906, **29**, 255.

The exports of 40 per cent. spirit increased from 1,647,000 wedro (of 12·3 litres) in 1902 to 2,303,000 wedro in 1903, these figures being 2·1 and 3 per cent. respectively of the total production of spirit in the country. The largest proportion of the exports, namely, 1,674,000 wedro, went to Turkey, the trade with that country being an increasing one, and showing a growth of 437,000 wedro for the year. The second largest foreign consumer is Germany, which took 142,000 wedro, against 91,000 the previous year. Port Arthur received 611,000 wedro and Dalny 20,000 wedro. On the other hand, the consumption by Greece declined from 12,000 to 2,000 wedro.

Exports of rectified spirit are increasing in proportion to raw spirit, the percentage of the former having grown from 22 per cent. of the total in 1894 to 96 per cent. in the year under report. The chief exporting centres are the provinces of Wolhynia, Kiew, and Kurek, the first and last of these, together with Estland, exporting rectified spirit exclusively, whereas Minsk, Warsaw, and Piotskow export only raw spirit. In addition to the general bounty of 5·5 per cent. on exported spirit, an additional premium of 1·5 per cent. is given in the case of rectified spirit.—C. S.

Glycerol in wine; New methods for the determination of ——. C. Billon. XXIII., page 779.

Alcohol; Denatured —— in Canada. Oil, Paint, and Drug Rep., July 9, 1906. [T.R.]

For over ten years Canada has had in force legislation whereby grain alcohol, denatured and known as methylated spirits, can be had for use in the arts free from revenue spirit tax at a price which bears a small profit to the department for supervision, over the cost of the grain spirit and the denaturants. So well has this arrangement worked that the agents of foreign countries, and particularly of the United States, have visited Ottawa, and based their methods of denaturing and control of the privileges upon the manner in which the Canadian government handles and controls their methylated or denaturing department.

Some years ago the government allowed denatured alcohol to be supplied by a concern which was allowed to buy grain alcohol "in bond free," mix it with 10 per cent. of wood alcohol, and sell it to the public, until it was discovered that an enormous amount of revenue was being lost to the government through the abuse of the mixing privilege, since the grain alcohol was being taken secretly and converted into whiskey and high wines instead of methylated spirits as intended.

After due consideration the government decided to assume complete control under its inland revenue department of the entire denaturing business, buying the grain alcohol and the denaturants, and adding only to the cost of each a profit to cover the expense of supervision and inspection.

Manufacturers who give a bond to the government that this methylated spirit shall not be purchased for re-sale, but will be destroyed in their own productions, are granted a purer spirit at a much lower price than the ordinary person buying for use other than manufacturing. Also soapmakers and perfumers who use very large quantities can, by having the methylated spirits stored in bond, and destroyed in their productions under the supervision of an officer, whose time they pay for, secure a still lower price and purer spirit from the department.

Alcohol: Industrial ——, in Australia. Pharm. J., July 7, 1906. [T.R.]

The first report of the Commonwealth Tariff Commission, appointed by the Federal Parliament last year, has just been issued. The recommendations are prefaced by a summary of the nature and methods of producing industrial alcohol. In view of the bounty paid in Germany on exported methylated spirit, amounting to about 5d. per liquid gallon, the Commission does not recommend the free import of this article into the Commonwealth. It was thought that a duty sufficient to counteract the German export bounty would be sufficient to protect local distilleries. A recommendation was therefore made that, in lieu of the present import duty of 1s. per gallon, there be imposed a duty of 6d. per gallon on methylated spirit of not less than 65 per cent. over proof, methylated in a manner satisfactory to a Commonwealth analyst. Other recommendations issued by the Commission are as follows:—

That spirit of not less than 65 per cent. over proof produced within the Commonwealth when methylated in bond be free; and that methylated spirit of less than

85 per cent. over proof shall not be manufactured within the Commonwealth.

That approved methylic alcohol and all approved methylating or denaturing agents shall be free for use in bond or on the premises of licensed methylators, subject to such regulations as may be prescribed.

That a registration fee of 1d. per gallon be payable upon all locally manufactured methylated spirit, such fee to be paid by means of adhesive revenue stamps affixed to all vessels in such manner as may be prescribed.

That methylated spirit be of three classes :—

(*a*) "Industrial" spirit, for use in the arts or manufactures (except of food, drinks, scents, essences, or tinctures), to be completely denatured by a general agent, *i.e.*, 2 per cent. of wood naphtha, with ½ per cent. of pyridine spirit.

(*b*) "Mineralised" spirit, for domestic lighting and heating, and for power purposes, to be completely denatured by the addition of 1 per cent. of wood naphtha, ½ per cent. of "pyridine," and from 2 to 20 per cent. of benzine and ½ per cent. of aniline violet or blue dye.

(*c*) Spirit for special manufacture may be denatured upon the premises where it is to be used, or upon the premises of a licensed methylator, by such special denaturing agents as may be prescribed by regulations to be approved of by Parliament.

That regulations be prescribed relative to the minimum strength below which it shall be unlawful to sell "industrial" or "mineralised" spirit, and the licensing of all dealers, provision being made that "industrial" spirit shall not be sold other than by a distiller or a licensed methylator; and as to the quantity which may be stored and sold by wholesale and retail dealers respectively. It is further recommended that spirits specially denatured shall only be allowed for the manufacture of fine chemicals and pharmaceutical products where such manufacture is kept entirely separate from the manufacture of tinctures and other preparations in which spirit remains as spirit in the finished product.

English Patents.

Kilns for drying malt and hops; Impts. in ——. E. G. Shew, Ledbury, Herefordshire, and W. Jones, Stourbridge, Worcestershire. Eng. Pat. 15,139, July 24, 1905.

The furnace of the kiln is provided with a dome or cover surrounded by a chamber, in which the air for drying the malt is heated before passing into the kiln. The air enters by passages at the bottom of the kiln, is heated in the chamber, and then escapes into the space below the drying floor. The products of combustion from the furnace pass through a number of zig-zag flues situated in the space below the drying floor, these pipes entering a central flue which pierces the floor, and reaches to the top of the kiln. The gases may be deflected into the space immediately above the malt, or pass up to the top of the flue, in either case causing a good draught through the kiln. During the removal of the dry malt or hops the gases pass off through a side flue fitted to the central flue just below the drying floor.—W. P. S.

Yeast; Process for the production of distillers' —— *from the raw materials, products, by-products, and residues of the manufacture of tapioca, sago, arrowroot, flour, and like materials.* O. E. Nycander, London. Eng. Pat. 18,393, Sept. 12, 1905.

A mash is prepared by mixing about 15 cwt. of the pith of plants which are used for the manufacture of arrowroot, sago, and tapioca, or of the by-products obtained in the manufacture of the flours, with 5 cwt. of malt and 6000 galls. of water, and heating the mixture to a temperature of 63° C. for one hour. The brew is then passed through a filter-press, and the clear filtrate mixed with about 10 cwt. of malt culms. After standing for three hours, the liquid is drawn off into a fermenting vat, where a sufficient quantity of yeast is added, and fermentation allowed to proceed in the usual way. The yeast developed during the fermentation is then separated and washed.—W. P. S.

Beer and the like; Production of non-deposit ——. L. Chew and H. J. West and Co., Ltd., London. Eng. Pat. 20,246, Oct. 6, 1905.

An apparatus is described by means of which small quantities (at a time) of beer can be cooled and carbonated. For this purpose three closed, cylindrical vessels communicating with each other and with a reservoir of carbon dioxide are employed. The communications are made through suitable pipes and two-way taps at the top of the vessels, and similar pipes and taps are provided at the bottoms of the vessels for filling and emptying the latter. All three vessels are surrounded by a cooling liquid, and by a suitable manipulation of the taps, the carbonating process may be made continuous; while beer is being pumped into one vessel, that in the second is being carbonated, and the contents of the third, fully cooled and carbonated, are forced out into the filter and bottling machine.—W. P. S.

Alcohol: Process for the recovery of vapours of ——, *pure or mixed with air, gases, moisture, or other volatile solvents.* Soc. Jules Jean et Cie., and G. Raverat, Paris. Eng. Pat. 13,602, July 1, 1905. Under Int. Conv., July 25, 1904.

See Fr. Pat. 345,138 of 1904; this J., 1904, 1231.—T. F. B.

French Patents.

Alcoholic fermentations in which malt is employed; Process for obtaining increased purity in ——. C. J. Somlo, First Addition, dated Jan. 12, 1906, to Fr. Pat. 331,578, April 29, 1903.

Before germination, the grain is treated in a grain-washing machine, mash-tun, or analogous apparatus, with tepid or hot water or steam, or with hot and cold water alternately, or with steam and cold water alternately.—T. H. P.

Distillery by-products; Apparatus and process for treating ——. L. Rivière. Fr. Pat. 362,654, Jan. 23, 1906.

The apparatus and process described are for the treatment of distillery residues, such as those which are freed from the greater part of their potash by precipitation on leaving the stills, and returned, with as small a loss of heat as possible, either to the diffusors or to the mash-tuns, or, after utilising the heat, to the drains. The apparatus also allows of the distillation under pressure and in presence of lime (with or without sodium hydroxide) of the ammonium compounds, which are condensed under a variable pressure, and afterwards transformed into ammonium compounds by means of acids. This elimination of the ammoniacal compounds may be followed by evaporation of the residue so as to allow of the extraction of the glycerin. This treatment may also be applied to the vinasses which have been used several times in the mash-tuns, and contain proportions of mineral and organic matters injurious to fermentation. It may also be extended to fermented liquids or wines, after these have been distilled to get rid of potash; these liquids are distilled to remove alcohol, and the residue transferred to the autoclaves for the extraction of ammoniacal nitrogen, either before or after passing through the diffusors or mash-tuns.—T. H. P.

ENGLISH PATENTS.

Centrifugal separators for liquids [*Milk, &c.*]. B. Ljungström, Stockholm. Eng. Pat. 5072, March 10, 1905.

THE invention relates to feed devices for separators, the milk being fed into the top of the liner or division contrivance instead of at the bottom, as usual. For this purpose the feed-pipe is placed centrally, and contiguous to it is provided an enlargement with passages for conveying the milk to the liner. Referring to the figure, which is a vertical section of the top portion of the bowl or drum, *a* is the drum, *b*, the feed-pipe, and, *c*, is the liner, the upper plate, *d*, thereof extending into the neck of the drum. This upper plate carries a flange, *e*, which bears tightly against the feed-pipe, holes, *f*, being provided for the passage of the separated cream to the exit. The plate, *d*, is also furnished with a circular projection, *g*, in which channels, *h*, are provided for the passage of the whole milk. The flange, *e*, and the projection, *g*, constitute the enlargement aforesaid. The upper ends of the channels, *h*, coincide with openings, *i*, in the wall of the feed-pipe, whilst the lower ends are opposite a series of holes in the plates, *c*, of the liner. The outlet, *k*, for the skimmed milk, and the cream outlets, *l*, and, *m*, are disposed in the ordinary manner.

Another modification of the apparatus is described in which the flange, *e*, is formed at the outside of, and in one with, the feed-pipe, and presses against the interior of the plate, *d*, on which the projection, *g*, is provided as before. The enlargement is, consequently, partly on the feed-pipe and partly on the upper plate. The projection, *g*, may be interrupted, or take the form of detached projections, sections, or humps. In separators where the discharge pipes for the skimmed milk are situated in the neck of the drum, the plate, *d*, need not extend into the neck of the drum. To prevent the skimmed milk from mixing with the separated cream, a ring is interposed between the plate, *d*, and the drum, orifices being made in it for the discharge pipes. The feed pipe and the upper plate, *d*, may be also made in one piece, the point where they emerge together being enlarged to form the flange, *e*, wherein the cream passages are placed. In this case the feed-pipe, *b*, and the casing forming the bearing for the driving shaft are preferably separate.—W. P. S.

[*Milk*] *Separators; Imps. in liners for centrifugal* ——. A. L. Christenson, Stockholm, Sweden. Eng. Pat. 23,991, Nov. 21, 1905. Under Int. Conv., Nov. 26, 1904.

INSTEAD of the recess usually formed on the inner edges of the superposed conical liners, the latter are provided with one or more ridges, formed on the upper surface of the conical plates, and extending in a direction oblique with regard to the radius of the liner. The object is to cause a retardation in the outflow of the whole milk from the central feeding pipe.—W. H. C.

Organic substances [*Foods*]; *Method of preserving* ——. R. Krause, Berlin, and R. Lenk, Vienna. Eng. Pat. 12,642, June 19, 1905.

THE substances to be preserved, such as meats, eggs, &c., are frozen, and the moisture removed by subjecting them to the action of cooled and dried air. The frozen articles of food may be also dried in closed chambers, the moisture being absorbed by suitable agents, such as calcium chloride, sulphuric acid, and the like, or removed from the chamber by means of an exhaust pump. The temperature to which the substances are cooled varies from 0° to —20° C.—W. P. S.

Fruit; Process for preserving ——. D. F. Sherman, New Castle, Cal., U.S.A. Eng. Pat. 13,245, June 27, 1905.

SEE U.S. Pats. 793,614 and 793,615 of 1905; this J., 1905, 853.—T. F. B.

UNITED STATES PATENT.

Food extract from cornstalks. A. G. Manns, Assignor to The Food and Fibre Products Co., Chicago, Ill. U.S. Pat. 820,806, May 15, 1906.

CORNSTALKS, either with or without the leaves, husks, &c., are boiled with water in an open vessel for three to five hours, or treated with superheated steam in a closed vessel for a shorter time. After separating the pulp, the liquid portion is concentrated under reduced pressure, and the residue granulated or powdered. The product is soluble in water, and contains on the average:—Moisture, 10 per cent.; ash, 14·3; proteids, 9·8; sucrose 9·2; and dextrose, 45·8 per cent. When the stalks have been stripped, less proteid is present in the food.—W. P. S.

FRENCH PATENTS.

Trypsin-zymogen; Preparation of ——. W. Hopmann. Fr. Pat. 362,615, Jan. 23, 1906.

CLAIM is made for a method of preparing trypsin-zymogen, an enzyme which causes the initiation or increase of the action of trypsin. The enzyme is obtained from intestinal mucus, spleen, human or animal intestinal secretions, or blood from the organs of animals previously treated with enzymes to precipitate the albuminoid matter, by breaking up or powdering the raw material, or by extracting by means of suitable liquids, or by precipitating these extracts by means of albumin and enzymes.—T. H. P.

Malt food; Process for making a ——. S. Felix. Fr. Pat. 362,773, Jan. 27, 1906.

AN infusion of kilned malt is prepared at a temperature of about 40° C., the infusion being then allowed to act on other foods, such as milk, meat, vegetables, &c., at a temperature of from 65° to 70° C. The residue obtained by the preparation of the infusion is also added, and the whole mixture finally dried under reduced pressure, and powdered or kept in the solid state.—W. P. S.

(*B.*)—SANITATION; WATER PURIFICATION.

ENGLISH PATENT.

Screening, straining, or filtering fluids [*water or sewage*]; *Apparatus for* ——. J. T. Briscoe, Enfield. Eng. Pat. 27,155, Dec. 29, 1905.

A CYLINDRICAL or spherical perforated vessel is mounted on a shaft so that it can rotate, and the shaft is supported at either end by uprights connected above by a cross-bar. If it is desired to use any filtering medium, the shaft is provided with a sleeve fitting loosely round it, and the filtering medium is packed between the sleeve and the casing. The apparatus is lowered into a vertical conduit, up which the sewage or other liquid to be purified is flowing, and is of such a size and shape that while it can freely rotate, it nearly fills the conduit, so that the liquid is compelled to pass through the cylinder from side to side. If some of the perforations get blocked, the pressure from below becomes unequal, and the cylinder rotates

and facilitates the clearing away of the obstructions, whilst when it gets too much blocked up to work, the filter and frame can be lifted bodily out and cleaned. —W. H. C.

FRENCH PATENT.

Water; Apparatus for the purification of ——. C. Schmidt. Fr. Pat. 362,993, Feb. 5, 1906.

SEE Eng. Pat. 1158 of 1906; this J., 1906, 440.—T. F. B.

(C.)—DISINFECTANTS.

Phenols combined with acids, and in admixtures with soap; Study of —— from the chemical and bacteriological standpoint. H. Schneider. Z. Hyg., 1906, **53**, 116—138. Chem. Centr., 1906, **1**, 1897—1898.

IT is known that in the case of phenol, if a hydrogen atom in the benzene ring, in the ortho or meta position with respect to the hydroxyl group, be replaced by a sulphonic group, the disinfecting power is increased, the effect being greatest when the substitution takes place in the ortho position. The author finds that an exactly similar action occurs in the case of the cresols. *p*-Cresol-*o*-sulphonic acid has a greater disinfecting power than phenol-*o*-sulphonic acid. By allowing cold concentrated sulphuric acid to act on cresol for 1—2 days, sulphuric acid esters of cresol are obtained, which are superior disinfectants to the corresponding cresol-sulphonic acids. The most efficient cresol disinfectants, however, are aqueous solutions of cresol containing free hydrochloric or sulphuric acid. In preparing these mixtures, the acid is added to an aqueous suspension of the cresol.

The view put forward by Fehrs (Centr.-Bl. f. Bakter. u. Parasitenk, **37** [1], 730) that in commercial cresol soaps containing equal proportions of cresol, the chief factor governing the disinfecting power is the composition of the crude cresol, *i.e.*, the proportions of ortho-, meta-, and para-compounds, is stated to be not altogether correct. The free alkali usually present in these soaps must also play an important part, experiments having shown that an addition of alkali hydroxide diminishes considerably the disinfecting power of cresol soaps, owing to the formation of less active alkali compounds. The nature of the fatty acid also has a considerable influence on the disinfecting power, soaps prepared with linseed oil being more active than those prepared with rape oil.—A. S.

ENGLISH PATENT.

Disinfectants, deodorisers, and moth and insect preventives. T. Smith and W. F. Davis, London. Eng. Pat. 6676, March 20, 1906.

SPENT gas lime is heated to a temperature of from 150° to 200° C. in the presence of a good supply of air. When cooled, 5 per cent. of its weight of chloride of lime is added, and the mixture obtained is employed as the base of the disinfectant compounds claimed, which consist of this base with varying quantities of phenol, cresol, camphor, naphthalene, pyridine, quinoline, or acridine, &c., or mixtures of the same. The compounds may be made up in the form of tablets, or prepared as a fluid by heating them with ammonia solution to a temperature of 90° F., and filtering.—W. P. S.

UNITED STATES PATENT.

Insecticide fertiliser. R. and M. Jenkner and J. Pleyl, Floridsdorf, Austria-Hungary. U.S. Pat. 824,791, July 3, 1906.

SEE Eng. Pat. 19,068 of 1904; this J., 1904, 1109.—T. F. B.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page* 712.)

ENGLISH PATENTS.

Papermaking machines; Smoothing apparatus for ——. C. Tittel, Gratwein, Austria. Eng. Pat. 2795, Feb. 5, 1906. Under Int. Conv., March 4, 1905.

PROVISION is made for keeping the web of paper "closed" and smooth during the drying operation, by passing it between polished smoothing-rolls, a pair of which is placed behind each of the drying cylinders of the first group. The "opening" of the web during drying is caused by the expulsion of the moisture in the form of steam, and, according to this invention, this "opening" effect is corrected by the rolls immediately after it has been produced on the drying cylinder.—J. F. B.

Cellulose articles: Direct production of coloured ——. F. and A. van den Bosch, Goch, and O. Müller, Cologne, Germany. Eng. Pat. 6942, March 22, 1906. Under Int. Conv., April 1, 1905.

CELLULOSE articles, such as threads, films, &c., prepared by dissolving the cellulose of cotton-seed hulls by the ordinary solvents of cellulose (Eng. Pat. 3211 of 1906) can be produced in a range of colours varying from red to pale yellow, by leaving in the cellulose a certain proportion of the natural colouring matter of the hulls. Darker shades can be obtained by adding to the cellulose the desired proportion of the coloured alkaline liquor obtained in the first stage of the treatment of the cotton-seed hulls. The coloured solutions of cellulose are formed into solid articles by precipitation in solutions with an acid reaction.—J. F. B.

Viscose; Manufacture of lustrous threads, bands, strips, and the like of ——. M. Müller. Eng. Pat. 10,094, April 30, 1906. V., page 753.

FRENCH PATENTS.

Drawings, documents, &c.; Process and apparatus for rendering —— transparent and waterproof. C. L. Crabb. Fr. Pat. 362,122, Jan. 2, 1906.

THE sheets of drawings, &c., to be rendered waterproof and transparent, are conveyed between two endless bands, the tension of which is adjustable, first through a bath of a substance suitable for the purpose, *e.g.*, paraffin wax ("about 12 parts") dissolved in alcohol ("1 part"), and then into a heated, closed chamber, where the bands are pressed between rollers. On emerging from the chamber, the bands are separated by a mechanical device, enabling the sheets to be withdrawn from between them and replaced by others. Pencil drawings on paper, thus treated, resemble in appearance, it is stated, drawings in ink on calico.—E. B.

Viscose threads [artificial silk]; Impts. in spinning ——. Soc. Française de la Viscose. Fr. Pat. 361,319, April 3, 1905. V., page 754.

GERMAN PATENTS.

Celluloid-like masses; Process of preparing ——. Rheinische Gummi- und Zelluloid-Fabrik. Ger. Pat. 168,497, July 22, 1903.

THE camphor in celluloid is replaced by sugar, starch, dextrin, &c., the sugar being first rendered soluble in alcohol by treatment with aldehydes. Five hundred grms. of cane sugar are heated for several hours, under a reflux condenser, with 125 grms. of 40 per cent. formaldehyde and 100 grms. of alcohol. The alcohol and the excess of formaldehyde are removed by heating on the water-bath, a current of air being passed through the product. A colourless, resinous mass, free from water, results, easily soluble in alcohol and ether.—T. F. B.

Cellulose threads and films; Process for preparing transparent, durable, and elastic ——. Verein. Glanzstoff-Fabriken A.-G. Ger. Pat. 169,567, Jan. 17, 1905.

CELLULOSE threads and films, prepared by coagulating cellulose-cuprammonium in sulphuric acid, are wound on cylinders, which are then rotated in concentrated caustic soda solution, washed with water or dilute acid, and dried under tension.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 714.)

Berberine reactions. C. Reichard. Pharm. Centralh., 1906, **47**, 473; Chem.-Zeit., 1906, **30**, Rep. 211.

BERBERINE possesses an intense yellow colour, and is one of the few vegetable bases forming a carbonate, $(C_{20}H_{17}NO_4)_2CO_3$. A characteristic black coloration is produced on adding concentrated sulphuric acid to a powdered mixture of berberine and ammonium persulphate. A mixture of chromic and sulphuric acids gives a blackish-green to black coloration with berberine. Berberine hydrochloride, when warmed with a concentrated solution of cobalt nitrate, shows a violet-brown to violet-red coloration.—E. F. A.

Cade oil [Empyreumatic oil of Juniperus oxycedrus wood]: its preparation and distinctive characters. C. Pépin. J. Pharm. Chim., 1906, **24**, 49—58.

Preparation.—Cade oil is distilled in the neighbourhood of Saint-Sauveur, Alpes Maritimes, and in the departments of Var and Gard. It is produced from the wood of wild *Juniperus oxycedrus*, this species being distinguished from other kinds of *Juniperus* by its bright orange-red fruits of the size of a hazel-nut. The wood is cut into billets, and packed in an iron pot, which is then inverted and luted over a concave stone; the centre of the concavity is pierced by an aperture to which the delivery tube is fitted. In some larger distilleries, the billets are laid in a pile on such a large hollow stone, and a kiln is constructed round them with bricks. In either case the plant is surrounded with fuel, consisting of the worthless wood of the juniper, and distillation is conducted *per descensum*. The tarry distillate is collected, and set aside for some weeks, when it separates into three layers, consisting of a thick tarry deposit, an intermediate aqueous stratum, and a floating layer of oil. The latter is cade oil. It is clear, lighter than water, fluid, and has a red-brown colour, and a distinctive smoky odour.

Test for genuine oil.—One c.c. of the oil is agitated with 15 c.c. of light petroleum spirit, and filtered. Ten c.c. of the filtrate are then shaken well with an equal volume of 5 per cent. neutral cupric acetate solution, and the mixture is allowed to separate. Five c.c. of the ethereal layer are withdrawn, mixed with 10 c.c. of ether, and filtered. The filtrate should be coloured brownish-yellow. In the presence of pine tar, it will have an intense green colour; by this reaction the admixture of 10 per cent. of pine tar may be readily detected. The test is virtually that of Hirschsohn, but with the important difference that that author considered the green colour to be characteristic of genuine cade oil.

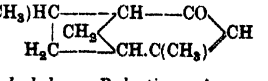
A specimen of so-called cade oil, distilled by a manufacturer of repute, was found not to respond to the above characters and test. It was then ascertained that it was not the product of the wood of *Juniperus oxycedrus* alone, but had been prepared from three distinct species of *Juniperus*.—J. O. B.

Rue; Essential oil of Algerian ——. H. Carette. J. Pharm. Chim., 1906, **24**, 58—62.

Two kinds of rue oil are distilled in Algeria, one in the summer, the other in the winter. The former, known as "essence de rue d'été" is the produce of *Ruta montana*. Its chief constituent is methyl-nonyl ketone. It readily congeals in winter, its solidifying point being 5°—8° C. In this respect it resembles oil of *R. graveolens*, which congeals at 8°—10° C. The oil distilled in winter, "essence de rue d'hiver," is derived from *R. bracteosa*, and consists chiefly of methyl-heptyl ketone; it does not solidify in winter, and requires exposure to a temperature of −18° C. before congealing; it melts again at −10° C. It is evident therefore that the mere determination of the congealing point is insufficient to establish the purity of rue oil, since this character varies with the species of *Ruta* employed as a source of the oil. All the rue oils examined were soluble, in the proportions 1:2 or 1:3 in 70 per cent. alcohol, so that any admixture of petroleum or of turpentine oil would be detected by this test.

In order to avoid confusion, it is suggested that the oil should be dealt with commercially under the names of the botanical sources, thus, "Oil of *Ruta bracteosa*," "Oil of *Ruta montana*," and "Oil of *Ruta graveolens*."
—J. O. B.

Camphor; Export of —— from Japan. For. Off. Ann. Series, No. 3675. [T.R.]



THE production of camphor in Formosa last year fell off considerably, and consequently the amount of camphor oil sent to the refineries in Kobe was also correspondingly less (49 per cent. of camphor is obtained from this oil). The output in Japan itself is limited, and cannot show much increase, at any rate till the distillation from the leaves gets beyond the experimental stage. The export from Japan therefore depends greatly upon supplies from Formosa, and at present these cannot meet the demand, though it is to be hoped that the workers in the Formosan camphor districts, with higher prices paid to them for their produce may be stimulated to further efforts.

The following table shows the shares taken by the principal countries in the export from Japan during the last three years:—

Year.	Value.					
	India.	France.	Germany.	United Kingdom.	United States.	Total Export.
	£	£	£	£	£	£
1905	53,000	58,000	12,000	26,000	100,000	262,000
1904	82,000	71,000	15,000	8,000	128,000	323,000
1903	61,000	37,000	68,000	50,000	117,000	361,154

Umbellulone; Constitution of ——. F. Tutin. Chem. Soc. Proc., 1906, **22**, 195—196.

THE ketone, umbellulone, was isolated from the essential oil of *Umbellularia Californica* by Power and Lees (Chem. Soc. Trans., 1904, **85**, 629; this J., 1904, 559), who showed it to possess the formula $C_{10}H_{14}O$. Umbellulone, on oxidation, yields a saturated keto-acid, $C_9H_{14}O_3$ (m.pt. 102°C.), called *umbellulonic acid*, which, on distillation under suitable conditions, is partially converted into an unsaturated lactone, $C_9H_{12}O_2$ (b.pt. 217°—220°C.). This lactone, on hydrolysis, yields umbellulonic acid, and is produced by the elimination of water from the enolic modification of the keto-acid. On oxidation, a polymethylene dicarboxylic acid, *umbellularic acid*, $C_8H_{12}O_4$ (m.pt. 120°—121° C.), is obtained, which is remarkably stable. By the bromination of umbellulone, and subsequent distillation of the products, *p*-cymene was obtained, together with substances containing bromine. It would therefore appear that the molecule of umbellulone has a structure capable of yielding this hydrocarbon without undergoing any profound change. The following formula is stated to offer the most satisfactory explanation of the behaviour of umbellulone on oxidation and on bromination:—

Unsaturated alcohols; Reduction of —— by metal-ammoniums. E. Chablay. Compt. rend., 1906, **143**, 123—126.

THE reduction of primary unsaturated alcohols by metal-ammoniums results in the formation of alcoholates, as obtained in former experiments on the saturated alcohols (this J., 1905, 634), but at the same time olefines are produced, instead of hydrogen being liberated. Using allyl alcohol the reaction is a very energetic one even at −40° C. It is only the alkali metal which is directly active, the ammonia being set free, and it has been found that when sodium alone acts on allyl alcohol, some propylene is formed, though mixed with hydrogen.—F. Sodn.

Cinnamic acid; Reduction of —— to cinnamene by [the ferments of] moulds. Oliviero. J. Pharm. Chim., 1906, **24**, 62—64.

THE ferments secreted by the moulds *Aspergillus niger* and *Penicillium glaucum* rapidly reduce cinnamic acid and its salts, with the formation of cinnamene, which is readily characterised by its powerful odour, resembling that of coal-gas. A filtrate from a culture of these organisms will at once reduce a solution of sodium cinnamate in this manner. The reaction suggests the employment of cinnamic acid for the detection of these moulds in dietetic preparations. The peculiar coal-gas odour often developed in the pharmaceutical syrup of balsam of Tolu is attributed to the occasional growth of the moulds therein.—J. O. B.

Ether; Duty on sulphuric —— in Switzerland. Bd. of Trade J., July 19, 1906. [T.R.]

A DECREE of the Swiss Federal Council, which came into force on the 5th inst., imposes a special duty on sulphuric ether (No. 1062 of the Tariff), in addition to the import duty proper, of 10 frs. per 100 kilos. (gross weight), to countervail the internal taxes levied on the alcohol employed in the domestic manufacture of that article.

Iodine; Division of —— between two solvents. Y. Osaka. Mem. Coll. Sc. and Eng. Kyoto Imper. Univ., **1**, 93—102; Z. Elektrochem, 1906. **12**, 473.

MEASUREMENTS have been made of the division of iodine between carbon bisulphide and mixtures of alcohol and water, the two solvents being practically immiscible. The following is a résumé of the results obtained:—Per cent. alcohol—30·5, 26·7, 22·9, 19·1, 15·3, 11·4, 7·6. Co-efficient (ratio of iodine in alcohol to iodine in carbon bisulphide)—0·0129, 0·0076, 0·0049, 0·0034, 0·0028, 0·0023, 0·0020. The values are the mean of those obtained with widely different concentrations of iodine. (See also this J., 1906, 282).—R. S. H.

Bismuth salts; Action of hydrogen peroxide on ——. L. Moser. Z. anorg. Chem., 1906, **50**. 33—37.

WHEN a solution of bismuth nitrate is added to alkaline hydrogen peroxide solution, the basic hydroxide, BiO.OH is precipitated. This contains no peroxide, but a small quantity of basic nitrate, which accounts for the fact that some chlorine is liberated on treatment with hydrochloric acid.—F. SODN.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 714.)

Ultra-violet rays; Absorption of —— by glass and apparatus used by photographers. A. J. Newton and A. J. Bull. Phot. J., 1906, **46**, 282—284.

THE spectrum of the iron arc, formed by a diffraction grating replica mounted on a concave surface, was photographed, and the absorption of the glass and other substances ascertained by exposing them in the path of the light. Photographs are given of the spectra obtained. All the lenses tried showed complete absorption of ultra-violet light up to 3170 A.U., most of them up to about 3,300. A Kahlbaum metal process-mirror reflected all the ultra-violet light recorded, without showing marked absorption; silver or glass mirrors gave marked but incomplete absorption between 2600 and 3300 A.U. A half-tone screen absorbed almost all the ultra-violet light up to 3300. The absorption of specimens of Jena glass 1 cm. thick, selected for their opacity to ultra-violet light, was in no case complete, whilst the yellow tint of the glass indicated some absorption of blue light. The importance of the ultra-violet light in process work, when an enclosed arc lamp is used, is shown by spectra of arc lights on a wet collodion plate, from one of which the ultra-violet was excluded by means of a solution of quinine sulphate; it is demonstrated that the greater portion of the effect of such light is attributable to the ultra-violet rays, and, when a pigment which absorbs these rays (*e.g.*, Chinese White) is used, the resulting negative is frequently faulty.—T. F. B.

Gelatinobromide; Action of alkali bromides in ——. B. Homolka. Phot. Korr., 1906, **43**, 216. Chem.-Zeit., 1906, **30**, Rep., 228.

THE author considers it probable that the production of "marginal fog" on negatives is due to the diffusion of the alkali bromide, in the emulsion, from the margin to the centre of the plate, under the influence of osmotic pressure. It is, therefore, stated that the alkali bromide of lowest molecular weight (*viz.*, lithium bromide) is the best to use for preparing plates as free from marginal fog as possible; it is shown that the greater the molecular weight of the alkali bromide used, the more complete and more rapid will be the diffusion of the bromide towards the centre of the plate.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 714.)

Dinitroglycerol. F. Volpert. Z. ges. Schiess.- u. Sprengstoffwesen, 1906, 169. Chem.-Zeit., 1906, **30**, Rep., 215.

THE author describes dinitroglycerol, an explosive introduced by Mikolajczak, as relatively safe and possessing the advantage that it does not solidify when exposed to a low temperature, such as would be met with in the arctic regions. It is more soluble in water than the tri-

nitrate; and can be mixed with ammonium nitrate to form explosives which keep well. It can be used as an ingredient of a "powder" which is good for shooting purposes, being non-corrosive and free from smoke.
—E. F. A.

"*Oxyliquit*" [*Liquid-air explosive*]. L. Sieder. Z. ges. Schiess.- u. Sprengstoffwesen, 1906, 1, 87—89. Chem. Centr., 1906, 1, 1915.

"Oxyliquit" consists of liquid air mixed with oxidisable substances, especially wood charcoal. The bursting effect of mixtures containing hydrocarbons, &c., depends upon the heat of combustion of the combustible substances. Petroleum carbon and cork charcoal have been used in place of kieselguhr as absorbing agents. The explosive acts well, but suffers from the disadvantage that its action is considerably diminished, especially in bore-holes of small diameter, by rapid evaporation of the liquid air. Liquid oxygen has recently been used in place of liquid air.—A. S.

Gunpowder and bullets, made about 1641, *recently discovered in Durham Castle.* O. Silberrad and W. S. Simpson. Chem. Soc. Proc., 1906, 22, 172—173.

The ammunition was found in a bucket which had been walled up in the roof of Durham Castle, probably having been placed there about 1641, when the Castle was armed against a Scottish raid. The bullets consisted of roughly moulded spheres of lead of two different sizes, some being 1·5 cm. and others 1·8 cm. in diameter. On analysis they were found to consist of 99·17 per cent. of lead, and to contain a small quantity of iron and silver, together with traces of bismuth, arsenic, and antimony. The gunpowder, on analysis, was found to approximate closely in composition to the black powder now used in this country. In appearance, however, it differed widely from powder manufactured at the present day, the ingredients having been merely ground and mixed together, no attempt at granulation having been made.

	Analysis of powder from Durham Castle.		Proportions used at present time in this country.
	On sample.	On dry material.	
Potassium nitrate	73·99	74·81	75
Carbon	14·71	14·87	15
Sulphur	9·98	10·09	10
Moisture	1·10		
	99·78		

These results are somewhat surprising, since the compositions used in this country during the seventeenth century all contained a much higher percentage of sulphur. It seems indeed probable that this powder was of Prussian origin, Prussian musket powder being the only explosive of this composition in use at that date.

The calorimetric value was determined by firing a charge at a density of loading, 0·48, in a closed vessel suspended in a calorimeter. The pressure recorded was 9·7 tons per sq. in., or 1478 atmospheres. The calorimetric value = 894 calories per grm. This is in close agreement with the figure given by ordinary black powder. The critical time of burning was determined at a density of loading of 0·230. The pressure recorded at this density was 4·51 tons per sq. in., 687 atmospheres; ordinary black powder fired at this density gives a pressure of 686 atmospheres (Sir Andrew Noble. Phil. Trans., 1905, 205, 15). The critical time of burning observed was 0·0030 second. This is more rapid than that of the granulated powders now in use.

Moisture: New method of determining ——, *with special application to moisture in cordite and other substances containing volatile matters other than water.* P. V. Dupré. XXIII., page 780.

English Patent.

Nitroglycerine-explosives; Manufacture of ——. H. W. Lake, London. From Dynamit A.-G. vorm. A. Nobel and Co., Hamburg, Germany. Eng. Pat. 6314, March 15, 1906.

Glycerol is converted into diglycerol by heating it under atmospheric pressure, and the product is either mixed with glycerin, and the mixture nitrated, or it is nitrated alone, and the tetranitrodiglycerol produced added to ordinary nitroglycerin, to obtain explosives of very low freezing point. It is stated that a nitroglycerin explosive obtained by nitrating glycerin containing 25 per cent. of diglycerol does not congeal when cooled to —18° C.
—A. S.

German Patent.

Nitroglycerin explosives; Process for the manufacture of gelatinous ——. Schachtebeck. Ger. Pat. 172,651, April 26, 1905.

The invention relates to the manufacture of gelatinous nitroglycerin explosives, in which wet collodion-cotton is used. The wet collodion-cotton is treated with glue, dextrin, starch, or similar substances for the purpose of absorbing the moisture. As an example an explosive of the following composition is given:—Nitroglycerin, 60·25; collodion-cotton containing 35 per cent. of water, 2·7; glue, 3·0; wood meal, 7·0; sodium nitrate, 24; and ammonium nitrate, 3 parts.—A. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 717.)

APPARATUS, &c.

Calorimetric method; New ——. M. Casaubon. J. Gas Lighting, 1906, 95, 41—42.

This calorimetric method consists in measuring the proportion of air required for the complete combustion of the gas, instead of directly measuring its calorific value. It is stated that, despite the differences in the calorific values of the variable constituents of a gas, it can be shown by calculation that an accurate determination of the heating power can be made by observing the ratio of air to gas. Even in the case of coal gas enriched with benzene, the error is only something like 8 calories per cubic metre. In carrying out the method, the gas is burned in a Bunsen burner to which the air and gas are supplied from separate meters, the flame being maintained in a closed space provided only with an orifice at the top for the escape of the products of combustion. By observing the appearance of the flame while the air supply is increased or diminished, one can see the exact point at which complete combustion is occurring, but an easier method of ascertaining this point consists in surrounding the flame with a mantle of oxide of cerium, and noting when the colour of the mantle changes from red to white. It is stated that an infinitely small change in the supply of air is sufficient to change sharply the red colour, due to a reducing flame, to a white colour, due to an oxidising flame. A ceria mantle is easily obtained by soaking an ordinary mantle in a 30 per cent. solution of cerium nitrate.—H. B.

French Patent.

Gases; Apparatus for the analysis of ——. Monopol Betriebskontroll-Apparate K. Steinbock. Second Addition, dated Dec. 4, 1905 (under Int. Conv., May 11, 1905), to Fr. Pat. 359,352 of Nov. 2, 1905 (this J., 1906, 394, 529).

The apparatus described in the principal patent and first addition thereto is here further modified, with the object of obtaining an exact, automatic registration of the results of the analysis.—H. B.

INORGANIC—QUANTITATIVE.

Platinum metals; Analysis of ——. [*Determination of osmium and palladium*]. N. A. Orlow. Chem.-Zeit., 1906, **30**, 714—715.

(1) To separate osmium from platinum, iridium, ruthenium, and rhodium, the solution is first treated with zinc or magnesium, and then hydrogen peroxide is added to the black precipitate thus formed. Osmium dissolves, and can be subsequently obtained as the pure tetroxide, whereas the other metals are insoluble.

(2) Palladium may be separated from the other metals of the platinum group by adding freshly precipitated silver iodide to a solution of their chlorides. This, unlike potassium iodide, reacts only with palladium chloride, yielding the black insoluble iodide, and leaving the other metals in solution. The palladium may be extracted from the precipitate by the aid of potassium iodide or thiocyanate solutions, or by means of *aqua regia*.—F. Sodn.

Boric acid [*in foods, &c.*]; *its detection and determination in large or small amounts.* W. H. Low. J. Amer. Chem. Soc., 1906, **28**, 807—823.

The chief points brought out by the author are the following:—

Detection of boric acid.—There is no necessity to dry the turmeric paper at the temperature of the water-bath. By carrying out the test at the ordinary temperature in a vacuum desiccator, or at 40°—50° C., in an ordinary desiccator, small quantities of boric acid can be detected in the presence of large amounts of other salts, and in the presence of substances such as nitrates and phosphates, that interfere with the test made in the usual manner.

Determination of boric acid.—If a water-absorbing substance, such as dry calcium chloride, be added to the solution under examination, it is possible to distil over the whole of the boric acid, by means of methyl alcohol vapour, without evaporating to dryness. Details of the methods of carrying out the tests are given, and also the proportions of boric acid found in various salts used in meat-packing establishments.—A. S.

Borates; Potassium and sodium —— [*and determination of boric acid in alkali borates*]. M. Dukelski. VII., page 757.

ORGANIC—QUANTITATIVE.

Cade oil; preparation and distinctive characters. C. Pepin. XX., page 776.

Glycerol in wine; New methods for the determination of ——. C. Billon. Sixth Internat. Congr. Appl. Chem., Rome, 1906. Wochensch f. Brau., 1906, **23**, 350.

In the opinion of the author the old methods for the estimation of glycerol in wine are both intricate and inaccurate. Treatment with alcohol-ether gives a very impure extract; conversion of glycerol in wine into other easily estimated substances is difficult and uncertain. The author has worked out the following methods:—

A. *Determination of glycerol in dry wines.*—Fifty c.c. of the wine are evaporated to 15 c.c. on the water-bath, treated with a slight excess of milk of lime, and then evaporated to dryness. The residue is triturated with a glass spatula, and mixed with 5 c.c. of strongest alcohol, again triturated, and treated with a further quantity of 5 c.c. of alcohol. The whole is poured into a 100 c.c. flask, and the dish rinsed into the flask twice, each time with 5 c.c. of alcohol. Ethyl acetate is then added in small quantities at a time until the flask is filled up to the mark, the whole being shaken after each addition. Owing to their insolubility in ethyl acetate, foreign substances are thus precipitated. The flask is shaken thoroughly for 1—2 minutes, and its contents filtered. Eighty c.c. of the filtrate (= 40 c.c. wine) are evaporated to a syrupy consistence on the water-bath at a temperature below 80° C. The residue is dried for an hour in an oven at 60°—70° C., and the pure, dry glycerol remaining is weighed. The author has shown by experiment that the results are satisfactory.

B. *Determination of glycerol in sweet wines.*—If the wine contain more than 10 per cent. of sugar, the glycerol obtained by the above method is somewhat contaminated with sugar. In such cases the method is modified as follows:—Fifty c.c. of the wine are concentrated to 15 c.c.; a quantity of lime, equal to the weight of sugar in the 50 c.c. of wine, is added, and the whole is evaporated to a syrup. The residue is treated with 10—15 c.c. of alcohol, and then heated to boiling. The alcohol is decanted into a 100 c.c. flask, and the alcoholic extraction repeated six or seven times. The alcoholic extract is cooled, made up to 100 c.c. with alcohol, shaken, and filtered. An aliquot part of the filtrate is evaporated to a syrup on the water-bath; the residue is taken up with 10 c.c. of alcohol, and then made up to a volume of 50 c.c. with ethyl acetate. The mixture is filtered, and an aliquot part of the filtrate evaporated to dryness, and the residue heated for an hour at 60°—70° C., and weighed.—L. E.

Casein in cheese; Determination of ——. A. Trillat and Sauton. Compt. rend., 1906, **143**, 61—63.

A method is described for the determination of the unchanged proteids in cheese, and is based on the precipitation of the casein in the presence of formaldehyde and acetic acid (see this J., 1906, 395). Two grms. of the cheese are rubbed down with 10 c.c. of hot water, a further 50 c.c. of water being added gradually. In the case of hard cheese, slightly ammoniacal water is used. The liquid obtained, is boiled for five minutes, 0·5 c.c. of 40 per cent. formaldehyde solution are added, and the heating continued for three minutes. After the addition of five drops of acetic acid, the precipitated proteids are collected on a weighed filter, extracted with acetone to remove fat, then dried at a temperature of 75°—80° C., and weighed. The method is particularly suitable for following the changes which take place during the ripening of the cheese, as will be seen from the following results obtained by the examination of a Roquefort cheese:—

Freshly-made cheese		19·48	per cent. of casein.
The same cheese, 8 days old		18·12	,, ,,
,, ,, 15	,, ,,	11·65	,, ,,
,, ,, 30	,, ,,	8·00	,, ,,
,, ,, 60	,, ,,	7·10	,, ,,

The products of the digestion of casein are not rendered insoluble by formaldehyde, as is proved by experiments on casein itself, and also on various samples of peptone and albumose.—W. P. S.

Morphine; Colorimetric determination of ——. L. Georges and Gascard. J. Pharm. Chim., 1906, **23**, 513—515.

The method depends on measuring the colour produced by iodic acid in solutions of morphine, either alone, or in the presence of a slight excess of ammonia. For purposes of comparison a standard solution containing 1·256 grms. of morphine hydrochloride is prepared; each c.c. of this contains 0·001 grm. of mono-hydrated morphine. A known volume of the neutral solution of morphine of unknown strength is treated with 5 c.c. of 5 per cent. solution of iodic acid, and is matched in the usual manner, with the colorimeter, against the standard morphine solution treated in a similar manner. The tint developed by iodic acid alone reaches its maximum in about 30 seconds; after about 15 minutes it begins to diminish. The colour produced by iodic acid and ammonia is not fully developed for two or three minutes. The method is useful as confirmatory of gravimetric results.—J. O. B.

Cantharidin; Determination of —— in cantharides. K. Siegfried. Schweiz. Woch. Chem. Pharm., 1906, 44, 342—345.

Fifteen grms. of the powdered drug are covered with 150 grms. of chloroform, 1 c.c. of hydrochloric acid is added, and the mixture is thoroughly agitated for several minutes; it is then set aside for 24 hours with occasional agitation. One hundred grms. of the chloroformic extract are then filtered into another flask, and the solvent is removed by distillation at the lowest possible temperature, the flask being well immersed in the water-bath. The residual cantharidin is then washed, and transferred to a small tared filter by means of 10 c.c. of light petroleum spirit, any adherent crystals being removed with a little more of the solvent. The filter and contents are finally dried to constant weight at 50° C. The yield of cantharidin should be at least 0·8 per cent.—J. O. B.

Moisture; New method of determining ——, with special application to moisture in cordite and other substances containing volatile matters other than water. P. V. Dupré. Analyst, 1906, 31, 213—218.

Water is estimated by measuring the amount of acetylene given off when it is allowed to act on calcium carbide. From 1 to 2·5 grms. of cordite, ground as for analysis, is weighed out in a tube of about 1 cm. diameter and about 12 cm. long. It is covered with a layer of sand, and calcium carbide filled in to a depth of about 5 cm., the sand being used to prevent the cordite from coming into contact with the calcium carbide. The tube is then connected with a nitrometer containing a saturated solution of common salt, and the apparatus adjusted to zero with the tube brought to a known temperature by immersion in cold water. It is next immersed in a water-bath at a temperature of 100° C. to a depth of 7—8 cm., and the heating continued until no further evolution of gas is observed. The tube is then brought back to its original temperature, and the volume of acetylene measured, and corrected for temperature and pressure. Owing to the fact that the lime which is formed retains a certain amount of moisture at 100° C., it was found that 1 c.c. of acetylene corresponds to 0·001725 grm. of water instead of 0·00162 grm. as given by calculation.—B. J. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES

(*Continued from page* 717.)

Cholesterol. A. Windaus. Ber., 1906, 39, 2249—2262.

Mauthner and Suida (Monatsh. Chem., 1896, 579) described three neutral products, *viz.*, α-hydroxycholestenol, hydroxycholestenone, and hydroxycholestendiol, obtained by oxidising cholesterol with chromic acid. The first of these, $C_{27}H_{42}O_2$, is probably an unsaturated secondary alcohol, whilst hydroxycholestenone, $C_{27}H_{40}O_2$, is the corresponding ketone, and hydroxycholestendiol, $C_{27}H_{42}O_3$, probably a saturated compound containing 1 mol. of water more than hydroxycholestenone. In the author's experiments 20 grms. of cholesterol were oxidised by means of chromic acid in acetic acid, and the products separated into neutral and acid compounds. The former, about 70 per cent., were purified, and finally yielded 5 to 6 grms. of pure hydroxycholestenone. The acid products, on treatment with acetone, yielded from 3 to 4 per cent. (calculated on the cholesterol) of an acid melting at 290° C., and having the formula, $C_{27}H_{44}O_4$. An acid with the same composition and properties has been obtained from cholesterol by Diels and Abderhalden (Ber., 1903, 3177; 1904, 3092).

Hydroxycholestenone.—The fact that an ethyl ester can be formed, indicates the presence of a hydroxyl group, but as the hydroxyl was not replaced by hydrogen when the compound was heated in a tube with zinc dust, it was not, according to Semmler, a tertiary hydroxyl group. A quantitative conversion of hydroxycholestenone into cholestandione was effected by boiling it for four hours under a reflux condenser with dilute acetic acid and zinc dust. From this the author concludes that since the double bond is so readily reduced, it must stand in the α, β-position with regard to at least one of the ketonic groups. The close relationship between hydroxycholestenone and cholestandione is also shown by the fact that both yield the same dibromide, melting at about 165° C.

Action of hydrazine on cholestandione.—About 70 per cent. of six-sided plates melting at about 188° C. and having the formula, $C_{27}H_{42}N_2$, were obtained. Here 1 mol. of the diketone reacted with 1 mol. of hydrazine, with the liberation of 1 mol. of water. This reaction is usually regarded as characteristic of β- and γ-diketones (in one isolated instance it has been observed with an α-diketone); and since cholestandione is not an α- or β-diketone, there remains only the 1 : 4 position for the two ketonic groups.

Action of hydrazine on hydroxycholestenone.—There was formed only a monohydrazone, $C_{27}H_{42}ON_2$, melting, after recrystallisation, at 160°—161° C.

Other derivatives of hydroxycholestenone.—When fused with *o*-phenylenediamine, and the product crystallised from hot ethyl acetate, hydroxycholestenone yielded a compound, $C_{33}H_{46}ON_2$, melting at 158°—159° C. This substance, which was readily soluble in chloroform, ether, and benzene, but only slightly soluble in alcohol and ethyl acetate, contained one more molecule of water than a quinoxaline derivative. It yielded an acetyl derivative melting at 148° C., and dissolved in concentrated sulphuric acid or alcoholic hydrochloric acid to form solutions of a beautiful purple colour. Compounds of hydroxycholestenone with acetic anhydride and sulphuric acid, and with aniline and sulphuric acid, are also described.—C. A. M.

Trade Report.

Government Laboratory; Report of the ——.

The report of the Government Laboratory shows that during the twelve months ended March 31, 1906, 2054 samples of "drugs, medicinal and toilet preparations," 1506 samples of "flavouring essences, essential oils, and perfumery," and 1112 samples of chemicals were tested at the Government Laboratory for liability to spirit duty. 320 samples of mineral acids, chemicals, drugs, vinegar, and the like were tested for the presence of arsenic.

The export of medicinal tinctures, flavouring essences, and perfumes under the special drawback regulations continues to increase. In the course of the twelve months under review 14,269 samples, representing 143,255 galls. of proof spirit, were tested, and there were few occasions for complaint with respect to inaccuracies in the traders' declarations. The total quantity of methylated spirit made shows a marked increase, amounting to over 3,821,000 galls., as against about 3,666,000 in each of the three previous years. Of this amount, 2,139,000 galls. represent the ordinary unmineralised or manufacturing spirit, and 1,688,000 galls. the mineralised methylated spirit chiefly sold by retail to the general public. The increase has been wholly in the mineralised spirit, which shows an excess of 177,195 galls., or more than 11 per cent., over the quantity made in the year ended March 31, 1905. The unmineralised or manufacturing spirit shows a slight decrease, being 23,108 galls. less than in the year ended March 31, 1905. This does not imply any lessened use of alcohol in manufacturing operations. During the year a considerable quantity of unmineralised methylated spirit has been replaced by alcohol denatured otherwise than with wood naphtha, and there has also been further use of more efficient recovery apparatus.

Seventy-four samples of special "petroleum ether," representing 2391 galls., for addition to the methylated spirit used in certain manufacturing operations, were also examined, and all were approved. The use of specially denatured alcohol for manufacturing purposes has been sanctioned in several additional cases, and the quantity of spirit of this kind used in manufacturing operations has increased during the year to 351,615 proof galls., as compared with 267,706 proof galls. last year, and 206,452 proof galls. in the year ended March 31, 1904. The total quantity of denatured alcohol of all kinds used for industrial purposes last year shows an increase of 207,000 galls. over 1905, and 262,000 galls. over 1904. A large number of samples of spirits recovered in various manufacturing operations, and of various special denaturing agents—camphor, toluene, animal oil, &c.—have been examined. No illegal use of methylated spirit has been detected at any manufacturing premises where its use has been sanctioned. In the great majority of the sheep dips examined, the chemical constituents have been found to be substantially what they had been stated to be. The total number of analyses and examinations made for the Revenue and other departments of the State was 106,799

SPAIN; NEW CUSTOMS TARIFF OF ——. [Cd. 3066]. Price 5½*d*.

This is a translation of the new Spanish Customs tariff which came into force on the 1st July, with comparison of the duties leviable under the tariff which was in force prior to that date. The new tariff rates quoted in this Return are the minimum rates, these being applicable to the merchandise of the United Kingdom, which is entitled to most-favoured-nation treatment. Special attention is directed to Schedule III. in the Return, containing particulars of the *entrepôt* surtaxes leviable on products of extra-European origin transhipped in a European port; also to Appendix I., containing explanatory notes relating to various items of the tariff; and to Appendix II., containing the provisions of the new tariff relating to the dutiable weight of merchandise and the Customs treatment of packings and coverings.

Chemicals; United States Census of ——. Oil, Paint, and Drug Rep., July 9, 1906.

THE Director of the Census has announced the result of the tabulation of the statistics of chemicals, including wood distillation products and sulphuric, nitric, and mixed acids, for the calendar year ending December 31, 1904, forming a part of the census of manufactures of 1906. The statistics indicate that there has been a substantial increase in this industry in the United States, as compared with the statistics of 1900, which covered the fiscal year ending May 31. The products cover only the chemicals manufactured and sold as such. They do not include products which are made and consumed in the establishment where produced.

Comparative figures for 1905 and 1900 are shown in the following summary:—

All other products	dols.	23,808,089	18,836,488

* Exclusive of chemical products valued in 1905 at $2,747,434, made in establishments engaged primarily in the manufacture of other products. The principal items covered by this amount were sulphuric acid, 50° B., 21,903 tons, valued at $194,478; nitro acid, 5,009,662 lb., valued at $224,046; crude wood alcohol, 129,357 galls., valued at $40,148; refined wood alcohol, 1,459,807 galls., valued at $808,639; acetate of lime, 5,242,696 lb., valued at $52,751; charcoal, 6,045,157 bushels, valued at $290,192; coal tar distilling products, valued at $288,645, and soda products, valued at $247,800.

† The total value, $1,905,368, only was reported for this group in 1900 under the heading "Electro-Chemical Products."

‡ Not separately reported in 1900.

New Book.

ANNUAL REPORT OF H.M. INSPECTOR OF EXPLOSIVES. Home Office. [Cd. 3044.] Price 2s. 2d.

THIS publication deals with the manufacture, storage, packing, conveyance, importation, and Government inspection of explosives. Details are given of the accidents by fire or explosion of which the Home Office had cognisance during 1904. These show a total of 341, causing 50 deaths, and injuring 348 people. Special chapters are devoted to petroleum and to carbide of calcium and acetylene.

Society of Chemical Industry

[illegible] Soap [illegible]

Patent Specifications may be obtained by post by remitting as follows :—

English.—9d. each to the Comptroller of the Patent Office, C. H. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 55, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of the Local Sections, are requested to take notice that under Rule 42 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 580 pages, was published in 1898; a few copies of this are still left, price 25s. A second volume, embracing the period 1896—1905, is in course of preparation, and will be ready for printing in [illegible] section both a subject matter and authors' [illegible] each will be a volume of about 900 pages, [illegible] the Journal. As the success of [illegible]

Changes of Address.

Death.

Zimmele, Harry B., 200, Bellfield Avenue, Pittsburg, Pa., U.S.A. July 9.

Patent List.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 17,253. Vandor. Process for sharpening tools by chemical means. July 31.
„ 17,362. Lorenz. Means for connecting the end of an india-rubber tube with the mouthpiece of an air pump.* Aug. 2.
„ 17,612. Aitken and Mackie. Apparatus for separating liquids from vapours. Aug. 4.
„ 17,813. Breh and Kahnert. Washing process and apparatus.* Aug. 8.
17,832. Mackenzie and Gibson. Packings for Glover and other towers, funnels, &c., used in processes for concentrating liquids and absorbing gases.* Aug. 8.
17,999. Meyer and Hastert. Apparatus for cooling and purifying gases. Aug. 10.
18,003. Ingram. Hydraulic separators particularly for precious stones and metals. Aug. 10.
18,014. Meyer and Hastert. Apparatus for cooling gases. Aug. 10.
18,029. Adams. Apparatus for the discharge of liquids. Aug. 11.
] 11,206 (1905). Johnson (Feld). Apparatus for subjecting gases or vapours to the action of liquids. Aug. 9.
16,035 (1905). Hargreaves. Heating and evaporating solutions and apparatus therefor. Aug. 9.
19,212 (1905). Fitz-Patrick, Lord Armstrong. Manufacture of briquettes. Aug. 15.
1804 (1906). Haigh, Wheeler, and Appleyard. Means for rendering certain substances non-conductive of electricity, waterproof and acid-proof. Aug. 15.
4079 (1906). James. Receptacle or container for viscous, semi-fluid, or like substances. Aug. 15.
4818 (1906). Claus. Expansion and closing apparatus for casks employed for pasteurising or like purposes. Aug. 15.
5348 (1906). Soddy. Means or apparatus for use in heating matter in high vacua to high temperatures in glass vessels. Aug. 9.
6363 (1906). Ekenberg. Filter-presses. Aug. 15.
7421 (1906). Mazza. Apparatus for separating the constituent elements of gaseous mixtures. Aug. 9.
8053 (1906). James. Receptacles or containers for semi-fluid or other like substances. Aug. 15.
13,358 (1906). Meek. Boxes or vessels for holding viscous fluids. Aug. 15.

II.—FUEL, GAS, AND LIGHT.

17,176. Dunn and Berriman. Liquid for controlling the evolution of gas from calcium carbide. July 30.
[A.] 17,194. Potter. Regenerative gas producers for water and other gases. July 31.
„ 17,214. Thompson. Gas producing plants for water and other gases. July 31.
„ 17,294. Lynde. Apparatus and appliances for producing gas from petrol and other hydrocarbons for lighting, heating, &c. Aug. 1.
„ 17,296. Hipkins and Pendlebury. Construction of gas producers and method of working them. Aug. 1.
„ 17,322. Woods. Manufacture of incandescent mantles. Aug. 1.
„ 17,347. Parker. Production of fuel. Aug. 1.
„ 17,622. Hooton, and The Ashton Gas Co. Producing or enriching gas for lighting or heating. Aug. 4.
„ 17,766. Sensenschmidt. Apparatus for burning off incandescing bodies. [Ger. Appl., Aug. 7, 1905.]* Aug. 7.
„ 17,910. Lemon and Freel. Apparatus for the generation and purification of acetylene gas.* Aug. 9.
„ 17,996. Wise (Solvay und Co.). Coke ovens.* Aug. 10.
„ 18,081. Becker and Greener. Gas producers. Aug. 11.
[C.S.] 16,226 (1905). Robeson and Bettington. Furnaces for burning pulverulent fuel and for treating pulverulent ores. Aug. 15.
„ 21,644 (1905). Thompson (Englo and Cahill). Artificial fuel and method of making it. Aug. 15.
„ 24,433 (1905). Marconnet. Gas generators or apparatus producing combustible gases. Aug. 9.
„ 968 (1906). Wielandt, and Torfkoks Ges. Method of and apparatus for producing coke from fuel containing a large proportion of water, such as peat and lignite. Aug. 9.
„ 2244 (1906). Justice (Phönix Elektrotechnische Ges.). Production of electric arc light and apparatus therefor. Aug. 9.
„ 3145 (1906). Streubel. Incandescent mantles. Aug. 9.
„ 8030 (1906). Rothberg. Coke ovens. Aug. 9.
„ 9800 (1906). Becigneul. *See under* VII.
„ 9988 (1906). Fairweather (G. Seyfarth und Sohn). Gas producers. Aug. 9.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 17,162. Kalle und Co., A.-G. Manufacture of red colouring matter. [Ger. Appl., Nov. 13, 1905.]* July 30.
„ 17,164. Johnson (Kalle und Co., A.-G.). Manufacture and production of reduction products of ortho-nitro-phenylglycollic acid and of isatine. July 30.
„ 17,558. Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of colouring matters containing sulphur. Aug. 3.
„ 17,559. Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of compounds containing sulphur. Aug. 3.
„ 17,611. Read Holliday and Sons, Turner, and Dean. Direct blue cotton dyestuffs. Aug. 4.
„ 17,743. Newton (F. Bayer und Co.). Manufacture and production of new azo colouring matters. Aug. 7.
[C.S.] 2622 (1906). Imray (Meister, Lucius, und Brüning). Manufacture of yellow azo dyestuffs. Aug. 15.
„ 7287A (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of certain naphthalene derivatives. Aug. 9.
„ 14,057 (1906). Kalle und Co., A.-G. Manufacture of a sulphur containing red colouring matter from thio-indoxylcarboxylic acid and from thio-indoxyl. Aug. 9.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 17,163. Kalle und Co., A.-G. Dyeing and printing red on textile fibre. [Ger. Appl., Nov. 13, 1905.]* July 30.

[A.] 17,239. Remington. Process for strengthening felts and woollen fabrics.* July 31.
,, 17,487. Giehler. Process for the production of transparent patterns on tissues.* Aug. 3.
,, 17,660. Schmidt and Handschin. Dyeing apparatus.* Aug. 4.
,, 17,772. Vaysse. Composition for removing the grease from wool and stains from linen and fabric. Aug. 7.
[C.S.] 16,902 (1905). Brossard. Apparatus for dyeing, cleaning, washing, &c. Aug. 9.
,, 2830 (1906). Simon and Weckerlin. Process of and apparatus for steaming fibres and fabrics. Aug. 15.
,, 7520 (1906). Vereinigte Kunstseidefabriken, A.-G. Process or method for the manufacture of artificial hemp-bast and the like. Aug. 9.
,, 14,087 (1906). Vittenet. *See under* XIX.
,, 16,078 (1906). Thiele. *See under* XIX.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

[A.] 17,554. Cowper-Coles. Process for ornamenting metallic surfaces. Aug. 3.
,, 17,643. Gardner. Printing on tin-plate to obtain dead or dull impressions. Aug. 4.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 17,175. Ogle. Decomposition of metallic sulphates. July 30.
,, 17,461. Morton, and United Alkali Co., Ltd. Furnaces for burning pyrites, &c. Aug 2.
,, 17,559. Johnson (Badische Anilin und Soda Fabrik). *See under* IV.
,, 17,864. Bambridge. Production of sulphurous anhydride. Aug. 9.
,, 17,865. Bambridge. Production of sulphur. Aug. 9.
,, 17,905 Read. *See under* XIIIA.
[C.S.] 24,226 (1905). Bacon. Manufacture of crystallised sodium monosilicate. Aug. 9.
,, 24,330 (1905). Jaubert. Preparation of oxygen by decomposition of oxygenated salts. Aug. 15.
,, 24,849 (1905). Harris. Apparatus for the generation of ozone. Aug 15.
,, 26,380 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture and production of stable dry hydrosulphites. Aug. 9.
,, 9800 (1906). Becigneul. Treatment of spent gas purifying materials for the extraction of sulphur and apparatus therefor. Aug. 15.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 17,520. Boult. (Marsden). Manufacture of building material.* Aug. 3.
,, 17,534. Wolman. Solutions for preserving wood and other fibrous material.* Aug. 3.
,, 17,569. Apperley and Hullinghorst. Manufacture of artificial stones and other plastic articles.* Aug. 3.
,, 17,646. Ford. Manufacture of artificial stone or sand-lime bricks. Aug. 4.
,, 17,748. Ohlsson. Impregnating wood, &c., in closed vessels. [Swedish Appl., Aug. 7, 1905.]* Aug. 7.
,, 17,761. Kelly. Composition for making or surfacing roads, paths and floors.* Aug. 7.
[C.S.] 19,180 (1905). Peters. Manufacture of Portland cement. Aug. 15.
,, 22,787 (1905). Watson. Manufacture of bricks from clinker and lime. Aug. 15.
,, 26,993 (1905). Hoettger. Preservation of wood. Aug. 15.

X.—METALLURGY.

[A.] 17,131. Moore and Heskett. Direct process of manufacturing iron and steel.* July 30.
,, 17,242. Massenez and Richards. Manufacture of steel. July 31.
,, 17,441. Ellis (Les Produits Chimiques de Croissy). Extraction of copper and other metals from pyrites.* Aug. 2.
[A.] 17,587. Jarvis. Manufacture of steel. Aug. 4.
,, 17,592. Ciantar. Extracting gold from sea-water. Aug. 4.
,, 17,615. Roechling and Rodenhausen. Means for obtaining thin liquid dross in electric furnaces for metallurgical purposes. Aug. 4.
,, 17,672. Cowper-Coles. Process for removal of scale and oxide from metallic surfaces. Aug. 7.
,, 17,758. Centralstelle für Wissenschaftlich-Technische Untersuchungen Ges. Manufacture of brass. [Ger. Appl., Aug. 21, 1905.]* Aug. 7.
,, 17,913. Harden, and Amalgahne, Ltd. Jointing of aluminium and flux therefor. Aug. 9.
,, 17,915. Smith, Harden, and Amalgahne, Ltd. Jointing of sheet lead, tin, zinc, &c., and flux therefor. Aug. 9.
,, 17,932. Marks. (Soc. Anon. G. Ansaldo Armstrong and Co.) Process for manufacturing armour plates and other steel objects or objects made from alloys of steel.* Aug. 9.
,, 17,933. Marks. (Soc. Anon. G. Ansaldo Armstrong and Co.) Process for manufacturing armour plates and other objects made of steel or alloys of steel.* Aug. 9.
,, 17,935. Marks (Soc. Anon. G. Ansaldo Armstrong and Co.). Manufacture of armour plates and other steel objects.* Aug. 9.
[C.S.] 16,226 (1905). Robeson and Bettington. *See under* II
,, 15,423 (1905). Churchward. Hardening and toughening of iron and steel. Aug. 9.
,, 16,374 (1905). Kingsley. Treatment of sulphide and other ores. Aug. 9.
,, 17,310 (1905). Hobson. Selective solvents for silver. Aug 15.
,, 2988 (1906). Newton (Westman Process Co.). Process for reducing iron ore. Aug. 15.
,, 6426 (1906). Hadfield. Treatment of magnetic materials. Aug. 9.
,, 13,186 (1906). Birmingham. Alloys. Aug. 15.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 17,617. Cowper-Coles. Process for the rapid production of electrotypes. Aug. 4.
,, 17,768. Bridge. Electrically treating air and other gases.* Aug. 7.
,, 17,981. Wetter (Schuckert und Co.). Apparatus for the electrolytic production and separate collection of gases. Aug 10.
,, 18,079. Bradley and Sahs-Schwabe. Electro-deposition of metals or alloys upon metallic and other surfaces. Aug. 11.
,, 18,080. Ramen. Method of precipitating metals electrolytically.* Aug. 11.
[C.S.] 14,995 (1905). Johnson (Badische Anilin und Soda Fabrik). Means for the production of long stable electric arcs. Aug. 15.
,, 1926 (1906). Edison. Process of making metallic films or flakes for use with active materials in alkaline storage batteries. Aug. 15.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 17,154. Imbert. Process for producing oxy-fatty acids.* July 30.
,, 17,656. Breda. Process for extracting fats.
[C.S.] 16,132 (1905). Spies. Candles. Aug 15.
,, 22,242 (1905). Haddan (Edson Reduction Machinery Co.). Process for converting into a marketable product vegetable or animal matter from which oily or greasy matter has been extracted. Aug. 9.
,, 25,204 (1905). Kessler Soaps, ointments, and the like. Aug. 15.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*A.*)—PIGMENTS; PAINTS.

[A.] 17,772. Vaysse. Composition for removing or renovating paint and varnish. Aug. 7.
,, 17,904. Read. Manufacture of barium sulphate or permanent white. Aug. 9.

[A.] 17,905. Read. Treatment of minerals or compounds of the alkaline-earth metals for the recovery of useful products. Aug. 9.

(*B.*)—RESINS, VARNISHES.

[A.] 17,245. Castle. Manufacture of floorcloths, linoleums, patent leathers, feltings, body belts, &c. July 31.

(*C.*)—INDIA-RUBBER.

[A.] 17,773. Rouxeville. Process for the manufacture of a substance having somewhat similar properties to gutta-percha, obtained by the transformation of a certain hydrocarbon. [French Appl., Aug. 7, 1905.]* Aug. 7

„ 17,775. Foelsing. Process for production of pure caoutchouc * Aug 7.

[C.S.] 3116 (1906). Hood. Method of and machine for purifying crude or reclaimed rubber, but applicable as well to gutta-percha and similar materials Aug. 15.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

[A.] 17,129. Inrig. Treatment of waste leather, raw hides or skins, hoofs, horns, and bones. July 30.

„ 17,295. Forbes. Mineral substitute for glue and process for making same. Aug. 1.

„ 17,772. Vaysse. Composition for removing fat from leathers and skins. Aug. 7.

„ 18,002. Osborne and Schupp Process of converting catechin into catechutannic acid. [Ger. Appl., Aug. 14, 1905.]* Aug 10.

[C.S.] 1787 (1906) Bryan. Process for hardening leather. Aug. 9.

XV.—MANURES, &c.

[A.] 17,512 Neech. Discharging apparatus for superphosphate pits. Aug 3.

„ 17,878. Macdonald. Process for making manures very dry and acid-free without mechanical heat. Aug. 9.

XVII.—BREWING, WINES, SPIRITS, &c.

[A.] 17,665. Hill and Hill. Brewing of fermented liquors.* Aug. 4.

„ 17,909. Ozonair, Ltd., and Rogerson. Brewing beer or other liquors. Aug. 9.

„ 18,045 Van Rijn. Continuous fermentation of liquids.* Aug. 11.

[C.S.] 22,709 (1905). Classen. Process for facilitating the fermentation of sugar solutions obtained from wood that contains tannin. Aug. 15.

„ 2584 (1906). Felix. Process of manufacturing malt preparations. Aug. 15.

„ 8601 (1906). Varga and Kölgyesi. Device for conducting the gases of fermentation from barrels into the open air. Aug. 9.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—FOODS

[A.] 17,116. Williams. Preparation of proteids from ground nuts.* July 30.

„ 17,649. Galbraith and Ross. Table waters. Aug. 4.

„ 17,825. Deutschmann. Method of obtaining animal serum.* Aug. 8.

[C.S.] 15,597 (1905). Zündel-Donati. Process for drying foodstuffs of vegetable origin. Aug. 9.

„ 19,521 (1905). Holgate and Jessop. Process of treating milk to produce artificial human milk. Aug. 15.

„ 22,640 (1905). Hunter. Preservation (*in vacuo*) of cooked meats or other edibles in glass or other receptacles. Aug. 15.

„ 26,794 (1905). Clarke. Manufacture of an alimentary product. Aug. 15.

(*B.*)—SANITATION; WATER PURIFICATION.

[A.] 17,267. Bridge. Purifying and sterilising water by ozonised air and apparatus therefor.* July 31.

[A.] 17,342. Felters, and Guilleaume-Lahmeyer-werke A.-G. Electrical sterilising apparatus. [Ger Appl., Aug. 1, 1905.]* Aug. 1.

„ 17,757. O'Brien. Earth closets and deodoriser and disinfectant for use therein.* Aug. 7.

„ 17,948. Ellis and Slade. Process for forming and filling bacteria beds and tanks for purification of sewage, &c. Aug. 10.

„ 17,997. Evans-Jackson (Oesterreichischer Verein für Cellulose fabrikation). Process and apparatus for purifying the water used in factories. Aug. 10.

[C.S.] 16,177A (1905). Clark (American Water Purifying Co.). Method and apparatus for purifying water by distillation. Aug. 9.

„ 10,206 (1906). Decloreq. Water purifying apparatus. Aug. 15.

(*C.*)—DISINFECTANTS.

[C.S.] 18,839 (1905). Power. Solid deodorisers or disinfectants. Aug. 9.

XIX.—PAPER, PASTEBOARD, &c.

[A.] 17,701. Liddle (Roonitz Exploiting Co.). Apparatus for making cellulose vessels or receptacles.* Aug 7.

„ 17,777. Linfoot. Manifold paper and process of producing it Aug 7

„ 18,030. Schloesser and Schloesser. Steaming paper and the like. Aug. 11.

[C.S.] 8960 (1905). Mather. Manufacture of cellulose from vegetable fibres. Aug 9.

„ 15,417 (1905). Lockett and Baker. Means for applying size to paper during manufacture. Aug. 9.

„ 19,330 (1905). Miles. Cellulose derivatives and process of making them. Aug 9.

Official Notices.

JUBILEE OF THE COAL-TAR COLOUR INDUSTRY.

Presentations to Sir William Perkin.

The meeting in connection with the international celebration of the 50th anniversary of the discovery by William Henry Perkin of the dyestuff "mauve," took place on July 26th at the Royal Institution in London, and was largely attended, among those present being Lady Perkin, Miss Perkin, Prof. W. H. Perkin, F.R.S., Mr. A. G. Perkin, F.R.S., and Dr. F. M. Perkin. Telegrams of congratulation were received from a large number of scientific societies and distinguished chemists in different parts of the world. Prof. Meldola, F.R.S., Chairman of the International Committee, presided.

Prof. Meldola opened the proceedings by offering the hearty congratulations of the meeting to the founder of the coal-tar industry, on having lived to witness the consummation of his labours. In offering him their best congratulations they hoped that he might yet be spared for many years to continue those brilliant researches with which his name had become associated during the later period of his life. It was also a matter of congratulation that they were able to refer to the recent mark of distinction which Sir William Perkin had received from the hands of the King. No more appropriate meeting place could possibly be found anywhere in the British Islands than that hall, the classical home in which, in 1825, Michael Faraday first discovered benzene, which was there on the table before them. The meeting which was held last February at the Mansion House had three objects in view. The first was the painting of a portrait of Sir William Perkin, the second the execution of a bust, and the third the presentation of the remainder of the fund for the endowment of chemical research in the name of Sir William Perkin. Those objects had been fulfilled, and it was in the first place his pleasing duty, on behalf of the subscribers, to present the portrait which had been painted by Mr. Cope (The chairman then unveiled the portrait, which represents Sir William Perkin in his laboratory with a skein of mauve-dyed silk in his hands.) The portrait, which was ultimately to become the property of the nation, would, they sincerely hoped, remain in the possession of Sir William Perkin for many years to come. Then there was the bust by Mr. Pomeroy, of which the original would be placed in the library of the Chemical Society, where it would act, as they hoped, as a reminder of the long association of Sir William Perkin with their society, and an incentive to all original chemical workers in this country.

Prof. Dr. Emil Fischer offered to Sir William Perkin for his acceptance the Hofmann medal, which has been awarded to him by the Deutsche Chemische Gesellschaft.' Speaking in German, he said that for two decades the Deutsche Chemische Gesellschaft had been proud to have inscribed upon its list of honorary members the name of Perkin. As the present president of the Society he rejoiced to give expression to the heartfelt sympathy which was entertained for Sir William Perkin in the wide circle of German chemists, and to say how highly they prized his achievements in advancing their science, and in creating a new branch of chemical industry. It was indeed a bold undertaking half a century ago for the 18-year-old youth to develop into a manufacture a happy scientific observation of the practical value of which he had correctly gauged the true importance, and thereby to create a new and special art, the flourishing children of which should soon awaken both the surprise and the delight of all who took an interest in colour. But his fellow-workers had a still greater cause for astonishment when, after 20 years of earnest and successful technical work, Sir William Perkin had returned to pure science, and presented them with those fruitful methods which had their root in that was well known to every organic chemist as "Perkin's reaction." Sir William Perkin had also turned his attention to the little explored boundary between chemistry and physics, and given to the world a new and valuable means of assistance for the solution of the problems of chemical structure. For all those distinguished achievements in the field of organic chemistry the committee of their society had resolved to award him the highest mark of distinction in its power to offer, and he was entrusted with the duty of handing to him the Hofmann medal, which commemorated the founder of the society.

Sir William Perkin expressed his indebtedness to the German Chemical Society for the honour which had been conferred upon him. Dr. Hofmann when in London was constantly at the meetings of the Chemical Society, and when he left England he realised the want of such a society in his own country. The first volume of the Journal of the German Chemical Society was very small, but its contents were exceedingly interesting to the coal-tar colour industry, as it contained Graebe and Liebermann's paper on the synthesis of alizarine from anthracene, a colouring matter which was now manufactured in enormous quantities and had superseded the madder root, the original source of alizarine. Again, the first paper in the volume was Baeyer's paper on the reduction of indigo blue, and the continuation of these researches eventually resulted in the artificial formation of that colouring matter also, and from the insight into its nature thus obtained, indigo was now being made in very large quantities and taking the place of the naturally produced dye. He realised the kindness which Germans had always shown to him and his family. At the tercentenary celebration of the University of Würzburg, a good many years ago, he received the honorary degree of Doctor of Philosophy, and again, only this week, he had received a similar degree from the ancient University of Heidelberg, given him in connection with this jubilee celebration. He valued greatly the Hofmann medal, established in memory of the great man under whom he studied chemistry, and from whom he learnt so much, Dr. Hofmann, by his enthusiasm and force of character, stimulated his natural desire for research, and helped to establish him in a course which he had pursued for more than 50 years. He also greatly appreciated the action of the German Chemical Society in sending that medal by their president, one of Germany's greatest chemists, from whose hands he felt it an honour to receive that distinction. Before resuming his seat Sir William Perkin returned hearty thanks to all connected with that jubilee celebration for the honour which they were paying to him. He could not say how much he valued the gift of his portrait painted by so distinguished an artist as Mr. A. S. Cope, and he felt sure it would also be greatly prized by his family and friends, and would add much interest to his home. They were all proud to know that it was eventually to become the property of the nation. He looked upon that portrait as a very special part which his countrymen had taken in reference to the jubilee of the coal-tar colour industry. That was by no means the first time his fellow-countrymen had conferred honours upon him. Some of the Universities and learned societies had on previous occasions done this in recognition of his scientific and technical work, but that gift was certainly the crowning one, and he thanked them all most sincerely for the kindly and generous feeling of which that portrait was the evidence.

Prof. A. Haller presented the Lavoisier medal to Sir William Perkin, together with an address from the Société Chimique de Paris. Speaking in French, he said he regretted that the president of the society was not able himself to bring these tributes of respect, but he had charged him with the agreeable mission of presenting them. The Lavoisier medal was offered in recognition of the fine work which for half a century Sir William Perkin had done both in pure and applied chemistry, and in witness of the fact that he was one of the first and most illustrious of those who had applied chemistry to industry in modern times.

Sir William Perkin, in reply, said that his chemical education was to some extent influenced by French

chemists, among whom were Prof. Cahours, Prof. St. Claire-Deville, Pasteur, Berthelot, and Prof. A. Wurtz. When mauve was first introduced the silk dyers took to it readily, but the cotton dyers and calico printers in this country did not seem at all keen about it. The French realised at once the value of the dye for general purposes, and immediately applied it to calico printing, with the result that when the patterns came into the market all the other calico printers quickly followed suit. As early as 1859 the Société Industrielle de Mulhouse awarded him a silver, and later in the year a gold, medal. This recognition of the importance of mauve was a great encouragement to him, and he had always greatly prized those two medals. He was proud to add to them the beautiful Lavoisier medal, and felt doubly honoured by receiving it from the hands of so illustrious a chemist as Prof. Haller.

Dr. LEO BAEKELAND presented a congratulatory address from American chemists, Prof. Dr. PAUL FRIEDLANDER one on behalf of the scientific and technical chemists of Austria, Prof. P. VAN ROMBURGH one from the chemists of Holland, and Prof. Dr. H. RUPE one from the chemists of Switzerland.

Prof. Dr. C. DUISBERG and Prof. Dr. MAX DELBRÜCK presented a congratulatory address from the Verein Deutscher Chemiker. Dr. Duisberg said that, as manager of one of the largest German colour works, he was personally pleased to present the good wishes of the "Verein," seeing that he and his German colleagues were now the gardeners in the large and extensive garden laid out by William Henry Perkin, 50 years ago, and as it was their lot to assist in cultivating the young plant planted by him when he invented the first aniline dye, mauve: and furthermore because they in Germany were now gathering the fruits from the large orchard, full of strong and mighty trees, which had grown up to full maturity within the past five decades from the then small and delicate plant. As heirs to the experiments made by Sir William Perkin in the year 1856, they regarded it as their sacred duty to be present in the English metropolis, most cordially to shake the hand of the esteemed and honoured forerunner in that particular scientific and technical branch, and to express to him their heartiest thanks for his great fundamental achievement. He presented a copy bound in mauve-dyed leather of a "lecture" delivered last June at the general meeting of the Verein held in Nuremberg by the distinguished *doyen* of German scientific chemistry, Adolf von Baeyer, "On Aniline Dyestuffs." After referring to the important work of W. H. Perkins' fellow-countryman, W. Noel Hartley, in measuring the absorption of the ultra-violet light in the case of numerous chemical compounds, and the valuable deductions made as regards the absorption phenomena of organic compounds, especially dyestuffs, and their bearing upon constitution in connection with the development of colour, Adolf von Baeyer concluded his lecture with these words. "The key to the knowledge of the nature of aniline colours lies in the basic properties of the carbon atom. The aniline colours which delight the eye have thus attained much more importance to science. Their rays are the torch which enlightens the path of the explorer in the dark regions of the interior of the molecule, and the man who has lit the torch is William Henry Perkin." Prof. Duisberg added that about 3500 German chemists, the members of their Verein, were present that day in spirit celebrating with them that unique festival. They sincerely wished the whole coal-tar colour industry, and especially the English organic chemical industry, prosperity and success.

Prof. HALLER then presented, on behalf of the Société Industrielle de Mulhouse, a medal and an address, stating, at the same time, that the Society had elected Sir William Perkin an honorary corresponding member.

Sir WILLIAM PERKIN, in thanking Prof. Haller, said that the first medal he had received was from the same Society.

Dr. CARO, on behalf of the Society of German Chemical Manufacturers, Prof. Gustav Schultz, on behalf of the Munich Chemical Society, Lord KELVIN, on behalf of the Royal Society, and Prof. MELDOLA, on behalf of the Chemical Society of London, also presented addresses of congratulation.

Sir WILLIAM PERKIN replied to each, and in reference to the address of the Chemical Society of London, said that the proposal of placing his bust, executed by the eminent sculptor, Mr. F. W. Pomeroy, in the rooms of the Chemical Society, was an honour which touched him deeply, as he had always taken keen interest in that Society, of which he had been a Fellow for 50 years. For 17 years he was Secretary and for two years President. It was to that Society that he had contributed nearly all his own researches, and he looked upon it as a kind of scientific home.

Dr. E. DIVERS, in presenting the address from the Society of Chemical Industry, said that the President, Mr. Eustace Carey, of Liverpool, who was, to his profound regret, unavoidably absent, had asked him, as being his immediate predecessor in office, to present to Sir William Perkin the address from that Society. Dr. Divers then referred to the fact that Sir William Perkin and himself, who were of the same age, had been boys together at the same school, the City of London School, where they had been each inspired with the desire to become a chemist by their master, Thomas Hall, a pupil of A. W. Hofmann. They had both been examined in chemistry by the late Sir Frederick Abel, and later on sent to the Royal College of Chemistry to study under Hofmann, Hall having, in both cases, persuaded their parents to let them follow their bent and devote themselves to chemistry. One difference between them had been that, in the City of London School, Sir William Perkin was already Hall's assistant behind the lecture table, when he himself, a year junior in school rank, was but one of the juvenile audience. Another difference was that his own stay in the Royal College of Chemistry was during the session when Hofmann gave his last course (1851—2) in the lecture hall of the College in Oxford Street, whereas Sir William Perkin attended a year later Hofmann's lectures at the Royal School of Mines in Jermyn Street, with which the College of Chemistry had just been incorporated. Thus it was that they lost sight of one another, on leaving the City of London School, until his own return from Japan. They had both been President of the Chemical Section of the British Association, and President of the Society of Chemical Industry. These facts must obviously have great significance to himself when he had at that moment the great happiness to present that address, fifty-five years after they had taken their first steps in chemistry together. The following is the text of the address:—

"SIR WILLIAM HENRY PERKIN, KT., LL.D., D.Sc., PH.D., F.R.S.

"The Society of Chemical Industry offers to you its warmest congratulations on the occasion of the Fiftieth Anniversary of that great event, momentous both in chemical science and in the industrial arts, your epoch-making discovery of the first coal-tar dyestuff.

"As a consequence of that discovery, you were left free, at an unusually early age, to follow any course your inclination might suggest, and in that freedom you have, to your honour be it said, unswervingly devoted your whole life to the prosecution of chemical research. In that career, your achievements have been so splendid that, even had it been possible to forget your discovery of the first coal-tar colour, these achievements alone would have gained for you that eminent position which you hold among chemists.

"Happy in the results of your own researches, you have the additional happiness of your sons following you with distinguished success, in the work of extending the boundaries of the science of chemistry.

"The Society remembers with pleasure that at its foundation you were chosen one of its Vice-Presidents, and that, three years afterwards, you became its President. It cherishes the recollection of the services you then rendered it and recalls with satisfaction that the Society early

awarded its medal to you as a further mark of its profound appreciation of your work in chemical technology.

"There only remains to the Society, to-day, at this international celebration of the Jubilee of the foundation of the coal-tar colours industry, to do homage to your great attainments and high character, and to wish you many happy years of health and activity."

EUSTACE CAREY,
President.

July, 1906.

Prof. PERCY FRANKLAND presented a congratulatory address from the Institute of Chemistry, Sir THOMAS WARDLE one from the Society of Dyers and Colourists, Prof. SMITHELLS one from the University of Leeds, and Mr. J. W. HELPS one from the Institute of Gas Engineers.

Prof. Dr. SCHULTZ presented Sir William Perkin with the doctor's diploma of the Technical Hochschule at Munich.

Scientific addresses were also given by Prof. Dr. A. BERNTHSEN, Director of the Badische Anilin und Sodafabrik, and by Prof. Dr. C. LIEBERMANN.

Sir WILLIAM PERKIN, in reply to all the congratulations received during the day, then said:—I am glad that this meeting is taking place in this institution, which I first visited 54 years ago, and for several successive Saturday afternoons sat up in that gallery an eager listener to some lectures which were being delivered. I was a schoolboy of 14 then, and my old schoolmaster at the City of London School, Mr. Thomas Hall, to whom I owe very much, who was interested in me on account of my great liking for science, induced me to write to that great and good man, Michael Faraday, who was about to give a series of lectures on electricity, telling him how much I should like to be allowed to attend them, and he very graciously sent me an order—written in his own hand—admitting me to the course. I little thought then that, in four years' time, I should be the fortunate discoverer of the mauve dye, a product which in an indirect way is related to Faraday's scientific work, for it was in 1825 that Faraday discovered benzene, which, as is well known, has been the initial product for the production of aniline from the commencement of the coal-tar colour industry, and, of course, for the mauve. This fact also connects the industry with the Royal Institution, because it was in this building that Faraday by his researches discovered benzene. And further, I little thought that in a few years' time—May, 1866—Faraday himself would come to the Chemical Society, as he did, to hear me give a lecture on "Colouring Matter Derived from Coal Tar," and then encouraged me by his remarks. These were all things that naturally never entered the mind. How much less could I have dreamed that 50 years after I had obtained the mauve I should be here at a golden jubilee celebration of the discovery of this dye? And, moreover, who could have formed any idea of the wonderful development of the coal-tar colour industry that exists to-day, started from such small beginnings, but which through the researches of an army of scientific men is now of such colossal magnitude? When this year opened, I received a New Year's card from my old friend Dr. Caro, whom I am delighted to see here to-day, in which he referred to this year as being the golden jubilee of this industry, and I thought it very kind indeed of him to have remembered it; but I little thought that I should hear any more about the matter, and not until a short time before the meeting which took place at the Mansion House was I privately told that something was going to be done, and to-day is the consummation of this "something." I feel, too, the very great honour which is being done me; but what I appreciate most deeply is that this jubilee celebration is an international one, in which nations on both sides of the globe are taking part. I do indeed feel greatly honoured by the gifts I have received and by the very numerous addresses from the learned and other societies, and also by the very kind congratulatory speeches that have been delivered by so many and such eminent men, and I do not know how to express myself adequately, and regret that time has prevented me from referring to them more fully. But, ladies and gentlemen, I feel that I cannot take all this honour to myself. There are others who deserve much of it, but are no longer with us. I refer to my late father and brother. They joined me when this industry was first started, the firm being known as Perkin and Sons. My father, who was a builder, was much disappointed when I took to chemistry, as he wished me to be an architect, but nevertheless, when I obtained the mauve, he risked most of the capital he had accumulated by a life of great industry in building and started the works at Greenford Green, evidently having great confidence in me. This was indeed a very noble act on his part, for which I have always felt very grateful, for, had it not been for this, I probably should not have been able to start this industry, as few would have been inclined to undertake the risks connected with the manufacture of such a new and untried product as the mauve dye then was. My father lived about nine years afterwards, and fortunately was rewarded by seeing the undertaking a success. My brother, Mr. T. D. Perkin, who was expected to follow my father's business, helped me in my first small manufacturing operations before the works were commenced. He afterwards conducted the commercial part of the undertaking with great assiduity, and also took a practical part in the works with great success, and we worked together harmoniously for 17 years, until the works were sold in 1873. Therefore it will be seen what a great extent the collaboration of my father and brother had to do with the early success of this industry, and consequently I feel that much of the honour so lavishly given me to-day should be accorded to them. It is certainly a very interesting coincidence that the president of the Chemical Society should this year be Prof. Meldola, one who has had so much practical experience in connection with the coal-tar colour industry, and has enriched it by his own discoveries of colouring matters, as well as by his researches, which have yielded much valuable information in connection with the scientific side of the industry. He has taken, I know, a most laborious and active part in connection with this jubilee, and I thank him most heartily for all his kindness, as well as that of all others who have assisted in this matter. There is one matter connected with this industry and its great development which is of interest, and that is the immense amount of employment it has created for men of all classes, and, of course, especially for the working classes. When one considers its ramifications and its influence on other industries, it is difficult to gauge this, but it is often a very pleasant thought to me, and I am also very glad to know that the comfort and well-being of the *employés* of some of the largest works abroad are studied by the principals, and suitable dwellings provided for them. And, of course, the end result of all our work should be the benefit of mankind. But when I look upon all the great results that have been obtained chiefly by the accumulated labours of scientific men, both inside and outside the works, and the skill of those who have assisted to carry out their discoveries, while I am thankful that I had to do with the beginning of this industry, yet I cannot but feel how humble a part I have taken in this matter, and how generous and kind all are in connection with this celebration in recognising my early labours and struggles. I might say much more, but I feel I must conclude. This manifestation of the honour you wish to do me, of the kindness and friendly feeling you have shown me, this gathering together of friends from far and near, some of them very old friends, is very gratifying to me at this period of life, when the sun is declining in the west and the evening is approaching; and I cannot but again reiterate how deeply I feel all that has been done, and again I thank you most heartily. At the same time, when I look back on my life and consider all the way I have been led, above all I thank God, to Whom I owe everything, for all His goodness to me, and ascribe to Him all the praise and honour.

Prof. GREEN proposed a vote of thanks to the Chairman and Managers of the Royal Institution, for the use of the theatre—the workshop of Davy, Faraday, and Tyndall, and the place where Hofmann often lectured. It was

appropriate that that celebration should take place there.

This was heartily accorded, and the proceedings ended.

In the evening a complimentary dinner was given to Sir William Perkin at the Hotel Metropole.

On Friday, July 27th, the Greenford Green Works, now empty and tenantless, were visited. This was followed by a garden party, given by Sir William and Lady Perkin at their residence at Sudbury, during which the visitors had an opportunity to inspect Sir William Perkin's private laboratory.

A soirée at the Leathersellers' Hall, St. Helens' Place, E.C., completed the international celebration.

INDUSTRIAL ALCOHOL AND METHYLATED SPIRITS.

New Excise Regulations.

The Commissioners of Inland Revenue, in pursuance of the powers vested in them, hereby prescribe the following regulations which are to be observed from and after the 1st day of October, 1906:—

Part I.—*As to spirits other than methylated spirits.*

1. In taking account of the quantity of spirits in the spirit store of a distiller the officer must carry to the debit side of the account the quantity of spirits computed at proof, which shall be from time to time duly conveyed into the store from the spirit receiver in the distillery, and must carry to the credit side of the account the quantity so computed, which shall have been sent out under permit.

2. There must be legibly cut, branded, or painted with oil colour upon the head of every cask in warehouse containing racked or blended spirits, in addition to the other marks required to be thereon, the word "Racked" or the letter "R" in the case of racked spirits, and the word "Blended" in the case of blended spirits.

3. The manner in which a permit or certificate is to be cancelled is to be by writing in large letters in ink across the same the word "Received" and the day and the hour of the receipt, or by drawing lines in ink across the permit or certificate, so as to prevent it from being again used for the removal of spirits.

Part II.—*As to spirits received for use in the arts and manufactures under section 8 of the Finance Act*, 1902.

4. The allowance payable under section 1, subsection 1, of the Revenue Act, 1906, in respect of spirits received for use under section 8 of the Finance Act, 1902, shall be paid to the person authorised to receive the spirits on production by him to the Collector of Inland Revenue for the collection within which the spirits are authorised to be received for use, of a certificate signed by the officer who shall have taken account of the spirits on receipt, and countersigned by the supervisor of the district, setting forth the quantity of spirits at proof which shall have been so received.

Part III.—*As to methylated spirits.*

5. All spirits to be used for methylation must be conveyed under bond to the premises where the methylation is to take place, and must there remain without alteration or change in the cask or package in which the same are delivered until an account of the spirits has been taken by the proper officer of Inland Revenue.

6. An authorised methylator must at the time of methylation mix with and dissolve in all spirits then methylated other than industrial methylated spirits as defined by the Revenue Act, 1906, in addition to the matter prescribed by section 128 of the Spirits Act, 1880, a quantity not less than three-eighths of 1 per cent. by volume of mineral naphtha of a specific gravity of not less than 0·800, and the mineral naphtha shall before the mixing thereof be examined and approved by the Principal of the Government Laboratory, or other officer appointed in that behalf.

7. The account to be kept by an authorised methylator of any industrial methylated spirits and any mineralised methylated spirits prepared or received by him, and of the sale or delivery thereof, shall be in the forms prescribed in the first and second parts, respectively, of the first schedule hereto annexed. The methylator shall enter in the appropriate account daily, and at any time when required by an officer, the quantity of methylated spirits made or received, and the separate quantities sent out, both in bulk and at proof, and he must keep the accounts at all times open for inspection by any officer of Inland Revenue.

8. Essential oil or other flavouring matter must not without the express sanction of the Commissioners of Inland Revenue be added to or mixed with methylated spirits.

9. Methylated spirits may be removed by a maker of methylated spirits from the place of methylation for exportation under the following regulations, *viz.*:—

(*a*) The methylator must give the proper officer 12 hours' written notice of his intention to export, and state in the notice the number of gallons to be exported and the time at which the officer's attendance will be required, which must be between the hours of 8 a.m. and 2 p.m.

(*b*) The quantity exported at any one time must not be less than 10 gallons.

(*c*) The spirits may be exported in casks or other vessels, each containing not less than 10 bulk gallons, or they may be exported in smaller vessels containing any number of complete gallons, provided the vessels are packed in cases or packages containing not less than 10 bulk gallons each.

(*d*) The casks or vessels must be marked and numbered in the prescribed manner, and be accompanied on removal by a permit written by the methylator and endorsed by the officer.

10. A retailer of methylated spirits must not sell or have in his possession for sale any methylated spirits other than mineralised methylated spirits, nor any methylated spirits containing any essential oil or other flavouring matter; but this regulation shall not prevent a retailer of methylated spirits, if duly authorised by the Commissioners, receiving or having in his possession industrial methylated spirits for use in an art or manufacture carried on by him.

11. A retailer of methylated spirits—

(*a*) Must not receive or have in his possession at any one time a greater quantity of methylated spirits for sale than 200 gallons;

(*b*) Must not receive methylated spirits from a retailer of methylated spirits in a quantity exceeding four gallons at a time; and

(*c*) Must not sell to or for the use of any one person more than four gallons of methylated spirits at a time.

12. The account to be kept by a retailer of methylated spirits shall be in the form given in the second schedule hereto annexed. The account is to be at all times open to inspection by any officer of Inland Revenue.

13. A retailer of methylated spirits must not use methylated spirits in any art or manufacture carried on by him unless he has been authorised by the Commissioners of Inland Revenue to do so.

14. A person who has been authorised to receive methylated spirits for use in any art or manufacture carried on by him, whether he holds or does not hold a licence as a retailer of methylated spirits, must obtain all methylated spirits received by him from an authorised methylator, and in the manner directed by subsection 4 of section 124 of the Spirits Act, 1880.

15. A retailer of methylated spirits, and a person authorised to receive methylated spirits, must on receiving any methylated spirits accompanied by a permit, or a document in the nature of a permit, keep the permit or document and deliver it to the officer of Inland Revenue who first inspects his premises after the receipt thereof.

16. The allowance payable under section 1, subsection 1, of the Revenue Act, 1906, shall, as regards spirits used in making industrial methylated spirits, be paid to the authorised methylator, on production by him to the Collector of Inland Revenue of the collection in which the methylating premises are situate, of a certificate signed by the supervisor and the officer who shall have witnessed the methylation, setting forth the quantity of spirits at proof which have been used for that purpose.

17. The regulations of June 15th, 1891, relating to the manufacture and sale of spirits, and that of November 17th, 1900, relating to permits are hereby annulled as from September 30th, 1906.

Dated this 11th day of August, 1906.

Signed by order of the Commissioners of Inland Revenue.

J. B. MEENS, Secretary.

ALCOHOL FOR INDUSTRIAL PURPOSES.

The Revenue Bill, which includes facilities for the use, without payment of duty, of spirits in arts and manufactures (this J., 1905, 397—426; *ib.* 706) has received the Royal assent. After having been considered in Committee, the report stage passed the House of Commons without discussion on July 27, and the Bill was read a first time in the House of Lords on the same date. The second reading was carried without dissent on July 31, and the third reading took place on the same afternoon. Rules and regulations for the use of duty-free spirit will be issued on October 1st next.

First Schedule.

First Part.

FORM OF STOCK ACCOUNT OF INDUSTRIAL METHYLATED SPIRITS TO BE KEPT BY AN AUTHORISED METHYLATOR.

M———, *Authorised Methylator.*

Industrial Methylated Spirits Made or Received into Stock.				Industrial Methylated Spirits Sent Out of Stock accompanied by a Permit.

MR. A. GORDON SALAMON IN THE CHAIR.

STUDIES OF BASIC CARBONATES.

I. Magnesium Carbonates.*

BY W. A. DAVIS, B.SC.

The investigation of which an account is now given was undertaken primarily with the object of explaining the difficulty, which not unfrequently occurs in softening waters, that when the amount of sodium carbonate (or hydroxide) is added which should suffice to remove the whole of the magnesium as carbonate, practically none of the "hardness" is destroyed, no magnesium carbonate being precipitable at ordinary temperatures.

At the same time, the hope was entertained of gaining information that would throw light on the formation of dolomite, $MgCO_3,CaCO_3$. This is a problem of which a solution has long been desired; and now that it has been shown, by the examination of the core obtained, under the auspices of the Royal Society of London, by boring into the coral reef in the island of Funafuti, that dolomitisation has taken place to very different extents at different depths ("The Atoll of Funafuti," Harrison and Sons, London), it is more than ever desirable to discover the conditions under which calcium carbonate may be converted into the double carbonate.

At an early stage in the inquiry, it was necessary to take into consideration the basic carbonates of magnesium; the results obtained were such that it became probable that the opinions which have long been held as to the nature of the basic carbonates generally, not merely those of magnesium, are erroneous in no slight degree. In the interest of the analyst, as well as of the student of qualitative analysis—to whom the formation of "basic" precipitates is the source of much tribulation—it is desirable that clearer views should prevail than those which are now stated in the text-books; this subject will be dealt with somewhat fully in the following pages.

The formation of a normal carbonate is almost confined to the alkaline-earth metals—calcium, strontium, and barium. In all other cases a so-called "basic carbonate" is obtained. The production of such a substance is usually regarded as the consequence of the hydrolysis of the normal carbonate. Mendeléeff, for instance, in his "Principles of Chemistry" (1897 Edn., I. p. 601), speaking of the basic carbonates of magnesium, states that "their formation shows the power of water to decompose the normal salt." The universal acceptance of such a view is apparently to be traced to Heinrich Rose, by whom it was advocated in a series of papers, published in 1851 and 1852 ("Ueber den Einfluss des Wassers bei chemischen Zersetzungen," Pogg. Annalen, **83**, 132, 417, 597; **84**, 52, 461, 547; **85**, 107, 304, 312; **86**, 99, 279). Rose considered that water, acting as a "weak acid," was able to decompose more or less completely the salts of the "weak" acid, carbonic acid.

There has been a tendency hitherto to regard all the "basic carbonates," formed from any one metal under different conditions, as definite compounds; indeed, no less than 15 distinct basic carbonates of magnesium, eight basic carbonates of copper, and seven of zinc are described and formulated in Dammer's Handbuch.

Great uncertainty has existed, however, with regard to the basic carbonates of magnesium. The *magnesia alba* of pharmacy is a substance of a very indefinite and varying character. In Dammer's Handbuch the formula assigned to it is $4MgCO_3,Mg(OH)_2,4H_2O$; in Moissan's "Traité de Chimie Minérale" it is represented as $3MgCO_3,Mg(OH)_2,3H_2O$; in the British Pharmacopœia (1898) it figures as $3MgCO_3,Mg(OH)_2,4H_2O$; Roscoe and Schorlemmer (II., 247) are more explicit, and write $[OH.Mg.CO_3.Mg.CO_3.Mg.CO_3.Mg.OH]$ *plus* two or three molecules of water of crystallisation. Brill (Zeit. anorg. Chem., 1905, **45**, 275) has stated quite recently that when magnesium carbonate is heated between the temperatures of 230° and 510°, no less than seven distinct basic carbonates are formed; and he not only assigns definite formulæ to the several products, but ascribes to each a definite dissociation temperature. Anderson (Chem. Soc. Trans., 1905, **87**, 261), after showing that the analyses of commercial varieties of magnesium carbonate cannot be reconciled with the simple formulæ which are given in the text-books, concludes that the "basic carbonates are substances of high molecular weight," and assigns to the materials which he analysed complex formulæ such as $20MgCO_3,21Mg(OH)_2,02H_2O$.

The possibility that most, if not all, of the basic carbonates are mixtures of several substances does not seem to have occurred to anyone hitherto. The only hint to be found in the literature that such is the case would appear to be the description given in the British Pharmacopœia of *magnesia alba* as consisting of "amorphous particles with numerous slender prisms intermixed."

Not only, moreover, have the "basic carbonates" of magnesium been regarded as definite substances, but special hypotheses have been brought forward to explain their formation; thus Bodländer (Zeit. phys. Chem., 1900, **35**, 31), in order to account for the abnormal properties of a solution of magnesium bicarbonate, as compared with those of solutions of calcium bicarbonate and barium bicarbonate, goes so far as to assume that the complex ion $(MgCO_3)_n.MgOH'$, can exist, considering this to be proved by the formation of a "basic carbonate" when the solution is warmed.

General Survey of Results.

Decomposition of magnesium hydrogen carbonate in solution.—From the results obtained by Treadwell and Reuter (Zeit. anorg. Chem., 1898, **17**, 170), it appears that whilst a solution of calcium hydrogen carbonate, $Ca(CO_3H)_2$, is stable at ordinary temperatures, a solution of magnesium hydrogen carbonate is only stable in presence of an excess of carbon dioxide; when the pressure of the carbon dioxide in the atmosphere above the solution falls sufficiently, decomposition sets in and crystals are deposited of a compound which has long been regarded as a trihydrate of magnesium carbonate, $MgCO_3.3H_2O$. When equilibrium is established, each litre of the solution is found to contain at 15° C., 1·954 grms., $Mg(CO_3H)_2$, and 0·6410 grm., $MgCO_3$.

The conclusion arrived at, in the present paper, is that the acid carbonate is not at first simply resolved into normal carbonate and acid, but that in solution, at ordinary temperatures, it undergoes hydrolysis in the sense of the equation—

$$Mg(CO_3H)_2 + H_2O = Mg(OH)(CO_3H) + H_2CO_3,$$

a *hydroxide-carbonate* being formed which may be regarded as a true basic carbonate. With the possible exception of the mineral hydromagnesite, this apparently is the only basic carbonate of magnesium which there is any reason to regard as a definite substance. As the temperature is raised, however, the acid carbonate appears to undergo alteration in other ways than that which is here contemplated (comp. p. 794).

Magnesium hydroxide-carbonate dihydrate.—The conclusion that the compound which has hitherto been regarded as the trihydrated carbonate, $MgCO_3.3H_2O$, is in reality a dihydrated hydroxide-carbonate, is based on the fact that this salt loses only two-thirds of its water, either when heated in a dry state at 100° in a current of air or when boiled with a liquid such as xylene (b.p., 137°), the remaining third being expelled only at a much higher temperature and always together with some carbon dioxide.

The hydroxide-carbonate dihydrate is formed as sole product when solutions of hydrogen magnesium carbonate are heated at temperatures not exceeding 80°. It is also

* Taken as read.

produced when the ordinary "basic" precipitate, which is formed on adding an alkaline carbonate to a solution of magnesium salt, is left in contact with a solution of carbon dioxide or of potassium hydrogen carbonate, and, therefore, when the precipitate is merely left in contact with its mother liquor or when moist precipitated magnesium hydroxide is exposed to carbon dioxide.

The substance obtained by these methods must be supposed to be a hydrated polymeride of the compound, $Mg(OH)CO_3H$, as it is but very sparingly soluble in water (to an extent equivalent to only about 0·8 grm. $MgCO_3$ per litre), whereas solutions can be obtained containing about 3 grms. of dissolved $HO.Mg.CO_3H$ per litre (and therefore supersaturated with respect to the ordinary form), either by the careful decomposition of the bicarbonate or by the action of water on the curious variety of the normal carbonate discovered by Engel.

Magnesium carbonate, $(MgCO_3)_n$.—At least two such substances are known, natural magnesite and the carbonate obtained by Engel by heating magnesium ammonium carbonate at 130°—140° in a stream of dry air (Compt. rend., 1899, **129**, 598); this latter is remarkable on account of the readiness with which it becomes hydrated, "slaking" as easily as lime and being converted ultimately into the dihydrated hydroxide-carbonate. It dissolves in water more readily than the latter substance, giving a solution containing about 2 grms. of $MgCO_3$ per litre; but the solution is not stable, and after a short time deposits crystals of the dihydrated hydroxide-carbonate. Magnesite, on the other hand, is insoluble in water and is not affected to an appreciable extent by boiling with water or with aqueous alkaline carbonates.

It cannot be supposed that either variety of the normal carbonate represents the fundamental molecule, $MgCO_3$; at present, unfortunately, no method is known of determining the degree of polymerisation attained to in such salts.

Magnesite, calcite, and dolomite, being isomorphous, are probably polymeric forms of the general type, $(M''CO_3)n$, in all of which n has the same value. Magnesite and dolomite should, therefore, be as resistant to the action of water as is calcium carbonate; this is found actually to be the case, no change whatever taking place on boiling them either with water alone or together with alkali.

Mixed magnesium carbonates.—The so-called "double salts," represented by formulæ such as—

$$MgCO_3,K_2CO_3,4H_2O$$
$$MgCO_3,KHCO_3,4H_2O$$
$$MgCO_3,Na_2CO_3,$$

which were first obtained by Deville (Ann. Ch. Ph., 1851, iii., **33**, 86) by the action of potassium hydrogen or sodium hydrogen carbonate on precipitated magnesium carbonate, are to be regarded as, respectively, normal or acid salts of magnesium hydrogen carbonate; they may be represented by such formulæ as—

$$Mg\begin{Bmatrix}CO_3K\\CO_3K\end{Bmatrix} \qquad Mg\begin{Bmatrix}CO_3H\\CO_3K\end{Bmatrix}$$

Reynolds (Chem. Soc. Trans., 1898, **73**, 262) has shown that a large number of such normal mixed salts can be prepared by precipitating a concentrated solution of potassium carbonate with the appropriate metallic acetate; well-defined, crystalline, mixed salts of potassium with the metals, bismuth, calcium, cobalt, copper, iron, magnesium, manganese, nickel, and silver, have been prepared in this manner. Reynolds appears to have been the first to recognise the existence of such mixed carbonates. Arnold has also recently pointed out (Ber., 1905, **38**, 1173) that nearly all precipitated carbonates are soluble in an excess of the alkali carbonate used as precipitant.

Mixed salts, having a considerable degree of solubility, are formed on adding a caustic alkali to a solution of magnesium bicarbonate, thus:—

$$Mg(CO_3H)_2+NaOH=Mg(CO_3H).CO_3Na+H_2O.$$
$$Mg(CO_3H)_2+2NaOH=Mg(CO_3Na)_2+2H_2O.$$

No solid is separated until the solution is heated to a temperature sufficiently high to cause decomposition of the mixed salt; such decomposition may give rise to very different products, according to the conditions. The acid salt,

$$Mg\begin{Bmatrix}CO_3H\\CO_3Na,\end{Bmatrix}$$

gives rise initially to magnesium hydroxide-carbonate dihydrate,

$$Mg\begin{Bmatrix}CO_3H\\CO_3Na\end{Bmatrix}+3H_2O=Mg\begin{Bmatrix}CO_3H\\OH\end{Bmatrix},2H_2O+NaHCO_3;$$

whilst the disodium salt decomposes in two ways:—

$$Mg\begin{Bmatrix}CO_3Na\\CO_3Na\end{Bmatrix}+H_2O=Mg\begin{Bmatrix}OH\\CO_3H\end{Bmatrix}+Na_2CO_3$$
$$Mg\begin{Bmatrix}CO_3Na\\CO_3Na\end{Bmatrix}+2H_2O=Mg(OH)_2+2NaHCO_3,$$

giving magnesium hydroxide-carbonate (or its dihydrate) and magnesium hydroxide, the proportions depending on the conditions. By heating it in boiling water or a solution of sodium hydroxide, the hydrated hydroxide-carbonate is further changed, giving a mixture of magnesium hydroxide and magnesium hydroxide-carbonate.

Decomposition of magnesium hydroxide-carbonate dihydrate by water.—When crystalline magnesium hydroxide-carbonate dihydrate is heated with boiling water, two actions take place simultaneously, the product consisting of a mixture of anhydrous magnesium hydroxide carbonate, $OH.Mg.CO_3H$, and magnesium hydroxide; if the boiling be continued during but a short period, some of the original material remains undecomposed in the mixture:—

$$Mg\begin{Bmatrix}OH\\CO_3H\end{Bmatrix},2H_2O=Mg\begin{Bmatrix}OH\\CO_3H\end{Bmatrix}+2H_2O$$
$$Mg\begin{Bmatrix}OH\\CO_3H\end{Bmatrix}+H_2O=Mg(OH)_2+H_2O+CO_2.$$

After boiling during about half an hour, the change goes on very slowly, as a coating of magnesium hydroxide is formed which protects the crystals. When a solution of magnesium hydrogen carbonate is boiled, at first a precipitate of crystals of the hydrated hydroxide-carbonate, $Mg(OH)CO_3H,2H_2O$, is produced; since this undergoes decomposition as the boiling is continued, the ultimate product is similar to that formed on heating crystals of the compound with boiling water, namely, a mixture of unchanged substance with anhydrous magnesium hydroxide-carbonate, $Mg(OH).CO_3H$, and magnesium hydroxide. The mixed character of the product is shown by its appearance under the microscope.

Basic carbonates of magnesium.—The substance obtained, at the end of an hour, on boiling a solution of magnesium hydrogen carbonate, having a concentration equivalent to 11·1 grms. $MgCO_3$ per litre, is represented by the expression $0{\cdot}319MgCO_3,Mg(OH)_2,1{\cdot}2H_2O$, or, roughly, $3MgCO_3,Mg(OH)_2,3{\cdot}5H_2O$. Judging from their appearance under the microscope, such substances, and indeed all varieties of the basic carbonate, are not definite salts but mixtures, in all cases, of the three compounds, $HO.MgCO_3H$, $HO.Mg.CO_3H,2H_2O$, and $Mg(OH)_2$ in varying proportions.

The extent to which *magnesia alba* differs in composition, according to the manner in which it is prepared, is not sufficiently recognised. Thus, its composition may approximate to that represented by the expression $3—4MgCO_3,Mg(OH)_2,3—6H_2O$; or the ratio, $MgCO_3:Mg(OH)_2$ may be nearly that of unity—for example, $20MgCO_3,21Mg(OH)_2,62H_2O$ (compare the analyses made by Anderson, *loc. cit.*, of commercial varieties of magnesium carbonate). When prepared with cold solutions of sodium carbonate and magnesium sulphate, the air-dried product has the composition $4MgCO_3.Mg(OH)_2.11H_2O$ (Rose). That this substance consists almost entirely of a mixture of the dihydrated hydroxide-carbonate with hydroxide in the proportions $4(OH.MgCO_3H.2H_2O)$; $Mg(OH)_2$ is shown, however, by its behaviour when dried at 100°, the product being then of the composition, $4MgCO_3,Mg(OH)_2,4H_2O$, that is to say, a mixture of $4(OH.Mg.CO_3H)$ with $Mg(OH)_2$, as would be anticipated from the fact that, when dried at 100°, the compound, $OH.Mg.CO_3H,2H_2O$ is converted into the anhydrous hydroxide-carbonate.

The so-called "basic magnesium carbonates" can be obtained by two methods: (*a*) by boiling a solution of magnesium bicarbonate during a prolonged period or by heating magnesium hydroxide-carbonate dihydrate with boiling water; (*b*) by precipitating a solution of a magnesium salt with an alkaline carbonate. When the latter method is used, a basic carbonate may be formed even at ordinary temperatures. In such a case it cannot be supposed that the water acts on a simple magnesium carbonate which is formed initially, converting it into a basic product, if the important fact be borne in mind, which was first elicited by Fritzsche in 1836 (*Pogg. Ann.*, 1836, **37**, 314), and afterwards confirmed by Favre (*Ann. Ch. Phys.*, 1844 [iii.], **10**, 483; Jacquelain, *ibid*, 1851 [iii.], **32**, 195) and Rose (*Pogg. Ann.*, 1851, **84**, 465), that if the basic precipitate which is formed on mixing solutions of magnesium sulphate and sodium carbonate be left in contact with its mother liquor during several days, it changes completely into the crystalline dihydrated magnesium hydroxide-carbonate, $OH.Mg.CO_3H,2H_2O$. In other words, instead of the normal carbonate or hydroxide-carbonate being decomposed by water at the ordinary temperature and converted into a basic carbonate, the so-called basic carbonate can take up carbon dioxide from the solution—which contains alkali hydrogen carbonate—forming a substance of the empirical composition of a normal carbonate, ($MgCO_3,3H_2O$), the product so formed being affected only with extreme slowness, if at all, by water.

When an alkaline carbonate is added to a solution of a magnesium salt, the first product is a mixed carbonate, formed according to the equation,—

$$2NaCO_3Na + MgSO_4 = Mg(CO_3Na)_2 + Na_2SO_4;$$

but, except in the most concentrated solutions, this at once undergoes more or less complete hydrolysis into hydroxide-carbonate and hydroxide. The so-called basic carbonate which is formed is therefore a mixture of these substances in proportions, which vary within wide limits as the conditions are varied. Every alteration in the conditions tends to modify the composition of the product: thus, Rose obtained products to which he assigned the following formulæ:—

1. $4MgCO_3,Mg(OH)_2,11H_2O$;
2. $4MgCO_3,Mg(OH)_2,6H_2O$;
3. $3MgCO_3,Mg(OH)_2,5H_2O$;
4. $2MgCO_3,Mg(OH)_2;2H_2O$.

The first was prepared by mixing equivalent quantities of magnesium sulphate and sodium carbonate dissolved in three parts of cold water; the second, by using the solutions hot and boiling the liquid; the third, by substituting potassium for sodium carbonate, and boiling; the fourth, by using more dilute solutions than in the third case.

Judging from the great variation in their composition, it is probable that the basic carbonates of metals generally, not only those of magnesium, are in most cases mixtures.

Evidence supporting the foregoing explanation.—Various observations which were formerly inexplicable may be interpreted without difficulty in the light of the explanation which has been given of the manner in which basic carbonates are formed.

1. The fact that it is possible to obtain either a normal or a basic carbonate without varying either temperature or concentration, as shown by Fritzsche, Favre, &c. (comp. above).

2. The fact that solutions of magnesium sulphate and potassium carbonate of suitable concentration can be mixed in equimolecular proportions without giving rise to a precipitate (Rose, *Pogg. Ann.*, **83**, 435). This is clearly because a soluble mixed carbonate is formed, according to the equation $MgSO_4 + 2K_2CO_3 = Mg(CO_3K)_2 + K_2SO_4$, and is proof that the first interaction is not that expressed by the equation—

$$MgSO_4 + K_2CO_3 = MgCO_3 + K_2SO_4.$$

As the proportions used are in the ratio, $MgSO_4:K_2CO_3$, half of the magnesium sulphate is unaffected. From the time of Black onwards, (*Magnesia alba*, 1755) it has been frequently observed that on precipitating a magnesium salt by alkaline carbonate a considerable proportion of the magnesium remains in solution, and is only removed by continual boiling. The explanation of this fact is now obvious.

3. In many cases, it has been shown that the precipitate which is at first formed, on adding an alkaline carbonate to a solution of a metallic salt, contains more or less admixed alkaline carbonate.

(*a*) *Magnesium.*—Thus, H. Rose has stated (*Pogg. Ann.*, 1851, **84**, 461) that when magnesium sulphate dissolved in ten parts of water is mixed with 2 mol. proportions of potassium carbonate, dissolved in a similar quantity of water, and the precipitate is separated after 24 hours, but not thoroughly washed, a product is obtained containing 11·6 per cent. of potassium oxide. The substance prepared by Rose must therefore have consisted, to a considerable extent, of the mixed carbonate $Mg(CO_3K)_2,4H_2O$ previously isolated by Deville.

(*b*) *Copper.*—On adding an alkaline carbonate to a solution of a copper salt, basic carbonates are precipitated which vary widely in composition, according to the conditions under which they are prepared: ultimately, copper hydroxide or copper oxide is obtained. Rose's analysis (*Pogg. Ann.*, 1851, **84**, 466) shows that the blue precipitate, which is at first formed on adding a solution of potassium carbonate, owes its blue colour to the presence of a considerable proportion of the blue mixed carbonate, $Cu(CO_3K)_2$, or hydrates thereof (compare Reynolds, *loc. cit.*). When the blue precipitate is stirred up with or washed with water, it at once loses its blue colour, becoming green, until, under favourable circumstances, the so-called green basic carbonate, $CuCO_3,Cu(OH)_2$, approximating in composition to malachite, is obtained. Whether this substance is a true basic carbonate remains to be determined. On adding an excess of alkali carbonate, the precipitate again becomes blue and dissolves, giving a solution of the blue mixed carbonate.

Considerable difficulty is experienced in quantitative analysis in washing many precipitated carbonates (for example, zinc carbonate) free from adhering (in reality combined) alkali. It is clear that the alkali will only be removed on washing at a suitable temperature, and with sufficient water to decompose the mixed carbonate present in the precipitate. The significance of this fact will be appreciated on reading Rose's papers.

4. If the conditions be such as to prevent the formation of a mixed salt with an alkaline carbonate, a normal carbonate is formed in the case of metals which ordinarily give rise to basic carbonates; lead salts, for instance, give more or less basic carbonates when precipitated with alkaline carbonates, but when a current of carbon dioxide is passed into a solution of lead acetate, nearly pure lead carbonate, $PbCO_3$, is obtained, whatever may be the proportion of water (Rose, *Pogg. Ann.*, 1851, **84**, 66). Obviously, the basic carbonate of lead cannot be formed by the decomposition of the normal carbonate by water.

Practical applications.—Two important cases in which the foregoing views receive a practical application may be referred to:—

1. *Softening of magnesian waters.*—When caustic soda is added to a very dilute solution of magnesium bicarbonate containing 5—250 parts "$MgCO_3$" per 100,000, only a soluble salt is formed, either $Mg(CO_3H)CO_3Na$ or $Mg(CO_3Na)_2$, according to the proportions used. The solution remains clear until heated sufficiently to decompose the soluble mixed salt, when a mixture of magnesium hydroxide and hydroxide-carbonate is precipitated. If the original solution contains less than 50 parts "$MgCO_3$" per 100,000, no precipitate is formed until the temperature is raised to 90°. Indeed, it is impossible to completely soften magnesian waters containing small quantities of magnesium sulphate, chloride, or bicarbonate by means of either sodium hydroxide or carbonate, unless the temperature be above 90°. The difficulty that is often experienced in practice in softening such waters is undoubtedly a consequence of the formation of soluble mixed alkali carbonates of magnesium. When the equivalent quantity of caustic soda is added to a solution of magnesium bicarbonate containing about 50 parts of "$MgCO_3$" per 100,000 and the mixture is

heated at 90° during five minutes, the amount of magnesium carbonate remaining in solution does not exceed 3 parts per 100,000.

2. *Solvay method of manufacturing potassium carbonate with the aid of magnesia.*—In this process the careful regulation of temperature is essential. In order that the mixed carbonate may be formed according to the equation $[3MgCO_3,3H_2O+2KCl+CO_2=MgCl_2+2(MgCO_3,KHCO_3,4H_2O)]$, it is necessary to prevent a reversal of the action by keeping the temperature below 24° by artificial cooling, and also to maintain carbon dioxide in excess. (See Salzberg Werke Neu-Stassfurt., D.R.P., 1900, 143,408, 143,409; 1901, 143,595, Zeit. angew. Chem., 1903, **16**, 730.) In decomposing the mixed carbonate, it is either gently heated with an excess of water, or it is mixed with magnesium oxide, which seems to combine with the carbon dioxide of the potassium hydrogen carbonate at a temperature not exceeding 20° (Deutsche Solvay Werke, D.R.P., 1901, 135,329; 1903, 157,354). In either case, potassium carbonate is obtained together with magnesium hydroxide-carbonate dihydrate. If a low temperature be maintained, all the magnesium is separated from the mixed carbonate as hydroxide-carbonate; if the temperature rise, a "basic" carbonate is produced.

Formation of normal carbonates and exceptional conditions giving rise to basic sulphates.—It would appear that the production of a normal carbonate is associated with a predominating tendency on the part of the simple molecule to undergo polymerisation. Thus the sulphates of the three metals, barium, strontium, calcium, are the least soluble sulphates, a fact doubtless to be attributed to polymerisation. Most sulphates are easily soluble in water and probably possess—at least in solution—a simple structure; the sparingly soluble calcium sulphate (anhydrite), strontium sulphate, and barium sulphate are probably polymerised sulphates of the type $(M''SO_4)n$. The tendency to polymerise so clearly shown in the sulphates extends to the carbonates. It is still uncertain (compare Arzfuni, Physikalische Chemie der Krystalle) what are the conditions determining the formation of calcite and aragonite on precipitating a calcium salt with an alkaline carbonate; it is clear, however, that the two substances can only differ in the complexity of their molecules. Such a view would help to explain the peculiar, indefinite stages which are usually manifest during the precipitation of calcium carbonate, a more or less gelatinous, colloidal form being first produced which only becomes crystalline after a time or when boiled with water.

Magnesium hydroxide carbonate is soluble not only in solutions of alkali carbonates, but to some extent in solutions of magnesium sulphate. In this case it is probable that a mixed salt, *e.g.*, $Mg<^{SO_4}_{CO_3}>Mg$, is formed in solution.

Such an assumption is not improbable considering the extraordinary tendency of magnesium to give mixed salts, such, for example, as kainite, $MgSO_4,KCl,3H_2O$ (perhaps $ClMg,SO_4K,3H_2O$). A mixed salt of this type might be decomposed by water in several ways, giving:—

(1) $OH.MgCO_3H+MgSO_4$;
(2) $Mg(OH)_2+MgSO_4+CO_2$;
(3) A true basic sulphate, thus:—

$$Mg<^{SO_4}_{CO_3}>Mg \rightarrow CO_2+H_2O+HO.MgSO_4.MgOH;$$
$$OHH \quad HOH.$$

(4) A basic carbonate-sulphate

$$Mg<^{SO_4}_{CO_3}>Mg+H_2O \rightarrow \begin{matrix} HCO_3.MgSO_4.MgOH; \\ \text{or} \\ SO_4H.Mg.CO_3.MgOH. \end{matrix}$$

or a mixture of these. Compounds of the type 3 and 4 have not been isolated in the case of magnesium, but Rose (*loc. cit.*), under certain conditions, obtained by the action of alkali carbonates on a solution of copper sulphate, (*a*) a basic copper sulphate; (*b*) a basic sulphate carbonate.

Magnesium carbonate is soluble also to a slight extent in solutions of potassium sulphate, potassium nitrate and potassium chloride. In the light of the preceding results, it may be suggested that a small proportion of the mixed salts, $KSO_4.Mg.CO_3K$, $NO_3.Mg.CO_3K$, $ClMgCO_3K$, is formed, owing to occurrence of reversible interactions, such as—

$$MgSO_4+K_2CO_3 \rightleftharpoons KSO_4.Mg.CO_3K \rightleftharpoons OH.MgCO_3H.+K_2SO_4.$$

It is probable that the salt, $KSO_4Mg.CO_3K$, is formed in addition to the salt, $Mg(CO_3K)_2$, when potassium carbonate is added to an excess of magnesium sulphate in a solution containing much potassium sulphate. Such a salt might give rise, according to the conditions, to magnesium hydroxide carbonate, magnesium hydroxide, basic magnesium sulphate, or basic magnesium potassium sulphate, $OH.MgSO_4K$, or to a mixture of these substances.

Experimental.

Four series of experiments are described in the following account. The first relates to the decomposition of magnesium hydrogen carbonate in solution; the second to the behaviour of the magnesium carbonates with water and dilute alkalis; the third to the nature of the so-called basic carbonates of magnesium; and the fourth to the decomposition by water and alkali of the magnesium sodium carbonates.

I.—Decomposition of Magnesium Hydrogen Carbonate in Solution.

Preparation of the solution.—At the outset of the inquiry, traces of alkali were found to cause a wide variation in the results; special precautions were therefore taken in preparing the solution of the bicarbonate. Ordinary magnesium carbonate contains sodium carbonate, which cannot be removed even by repeated extraction with boiling water. The following method, however, ultimately gives a solution of magnesium bicarbonate which does not colour a Bunsen flame yellow. Commercial purified "crystal" magnesium carbonate is boiled with successive large quantities of water in a two-litre Jena flask, each time during about a quarter of an hour; it is then converted into bicarbonate by passing carbon dioxide (purified by passage through powdered potassium carbonate, cotton wool, and two or three washing flasks) into about 7 litres of water, in which about 150 grms. of the solid is suspended, contained in a large hard glass bottle; the rate of dissolution may be increased by passing in the gas under pressure. When nearly all the solid is dissolved, the solution is filtered and then decomposed by boiling; the liquid, containing practically all the alkali, having been decanted from the precipitate, a fresh quantity of water is added, and the solid again converted into bicarbonate; if necessary the treatment may be repeated.

Decomposition experiments, between 25° and 65° C.—The solution of magnesium bicarbonate which was used contained 11·07 grms. $MgCO_3$ per litre (= 19·21 grms. $Mg(CO_3H)_2$ per litre); usually, carbon dioxide in excess of that required to form the bicarbonate was present to the extent of 2 or 3 per cent. The amount in the stock solution was never allowed to fall below that corresponding with the presence of the whole of the magnesium as bicarbonate.

The object aimed at was to ascertain the actual amount, at different temperatures, of magnesium bicarbonate and magnesium carbonate in solution, at the moment when crystals of the empirical composition, $MgCO_3.3H_2O$, began to separate from a solution containing originally only bicarbonate. All the experiments were made in the same way, so as to be comparable. In order to exclude alkali, flasks of Jena glass were used throughout. About 55 c.c of the solution of magnesium hydrogen carbonate was introduced into a long-necked, round-bottomed flask, capable of containing 100 c.c., and heated as quickly as possible, over a small flame, to the temperature required to effect the decomposition. The temperature was observed by means of a thermometer reading to ½°, the bulb of which was kept immersed during the whole period of heating. During the decomposition, the liquid

the evolution of gas. As the manner of shaking is an important factor in regulating the decomposition, special care was taken to ensure uniformity in this respect. The temperature was maintained constant to within $\frac{1}{4}^{\circ}$. Directly the first sign of a crystalline precipitate became visible, the time during which heating had been effected having been noted, the solution was rapidly cooled under the tap, in order to prevent further precipitation, and filtered. By means of a standard pipette 25 c.c. was measured into the apparatus in which the total carbon dioxide was estimated, and another 25 c.c. was titrated with standard acid (1·065 *N*/10 HCl), using methyl orange as indicator. The operations were carried out as quickly as possible.

Method of estimating carbon dioxide.—In order to ensure complete expulsion of carbon dioxide from the portion of the liquid used for the analysis, the following method was adopted:—The 25 c.c. of the solution of bicarbonate was measured into the round-bottomed, 100 c.c., flask, A, connected, as shown, with the small distilling flask, B, and the U-tubes, C and D. C contained calcium chloride, and D was filled half with calcium chloride and half with pumice impregnated with anhydrous copper sulphate. Into A, was introduced 0·1 grm. of thin * aluminium

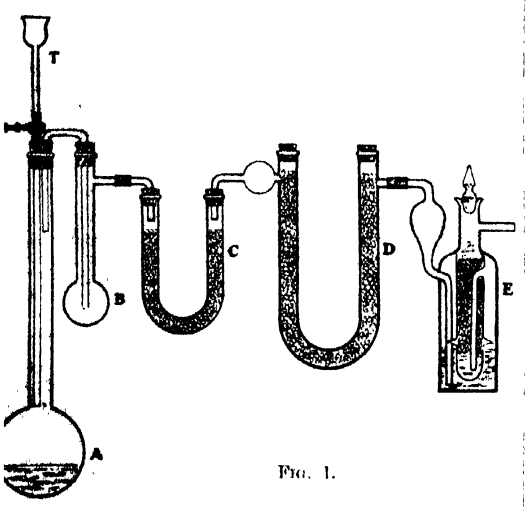

FIG. 1.

urnings; the rubber stopper was replaced and chlorhydric acid (3 c.c. of acid, 1·2, diluted with 2 c.c. of water) was added, gradually and as required, from the thistle funnel, T—a screw clip, S, serving to regulate the addition of acid. The carbon dioxide was absorbed in a potash bulb, E, of the remarkably efficient type, described by Wetzel (Ber., 1903, **36**. 161). A guard-tube containing soda-lime was attached to E. Care was taken to regulate the addition of acid, so that the carbon dioxide was evolved slowly. When all the acid was added, the liquid was gradually warmed, to cause the aluminium to dissolve in the acid. The hydrogen thus generated not only drives forward the carbon dioxide, but expels the greater part of that dissolved in the water. Finally, the liquid was gradually raised to the boiling point and kept in ebullition during about 15—30 seconds. After boiling, a U-tube containing soda-lime was put in place of the thistle funnel, and air aspirated through the whole apparatus. The flask, B, served as a condenser to prevent steam passing into the calcium chloride tube, C; for it may be substituted a piece of thin-walled glass tube, about 2 ins. long, sloping upwards, and drawn out at one end, so as to pass through the stopper of flask, A, and connected at the other with tube, C, by means of a rubber stopper and a piece of glass tube. To boil the liquid once is usually sufficient; but for safety the boiling and aspiration of air should be repeated. The aluminium serves two purposes: (1) it ensures the rapid expulsion of carbon dioxide dissolved in flask, A: if it be not used the liquid has to be boiled several times; and (2) it causes the liquid to boil regularly. Several tests made with pure calcite, to ascertain the degree of accuracy, showed that, using 25 c.c. of liquid in A, and weighing 0·25—0·30 grm. carbon dioxide (as in the experiments in Table I.), the probable error in the carbon dioxide weighed does not much exceed 1 part in 1000.

Results of experiments.—Table I. summarises the results* obtained at different temperatures on decomposing a solution of magnesium hydrogen carbonate, containing 11·07 grms. $MgCO_3$ per litre.

Note.—25 c.c. of the original solution = 61·5 c.c. of acid (1·065 *N*/10).

* The turnings must not be so thin as to dissolve rapidly at the ordinary temperature. Aluminium powder cannot be used.

* Example of an actual experiment showing method of calculation:—

Temp. = 29°. Time until first sign of precipitation was observed = 58 mins.

25 c.c. of filtered decomposed solution required 61·20 c.c. of 1·065 *N*/10 acid and gave 0·2700 grm carbon dioxide.

61·20 c.c. of acid = 61·20 × 1·065 × 0·0022 = 0·1434 grm. carbon dioxide.

"Half-bound" carbon dioxide = 0·2700 − 0·1434 = 0·1266 grm. carbon dioxide.

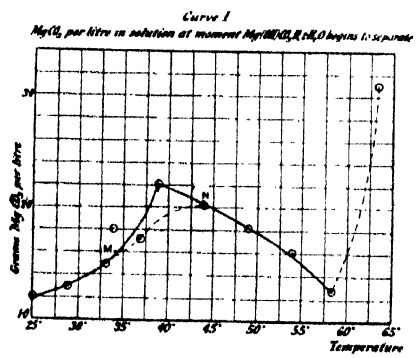
∴ In 25 c.c. of solution, $Mg(CO_3H)_2 = 2 \times 0{\cdot}1266 \times \frac{146{\cdot}4}{88{\cdot}0} = 0{\cdot}4212$ grm.

In 25 c.c. of solution, $MgCO_3 = (0{\cdot}2700 - 0{\cdot}2532)\ \frac{84{\cdot}36}{44} = 0{\cdot}0322$ grm.

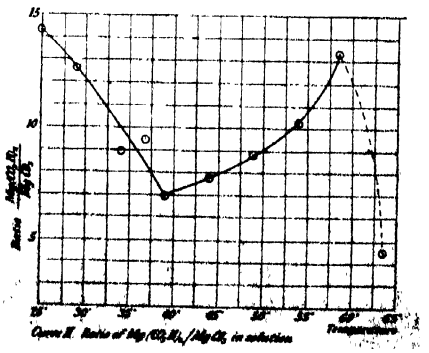
Correction for $OH.Mg.CO_3H$, $2H_2O$ separated (calculated as $MgCO_3$):—

25 c.c. of the original solution, before decomposition, neutralised 61·5 c.c. acid.

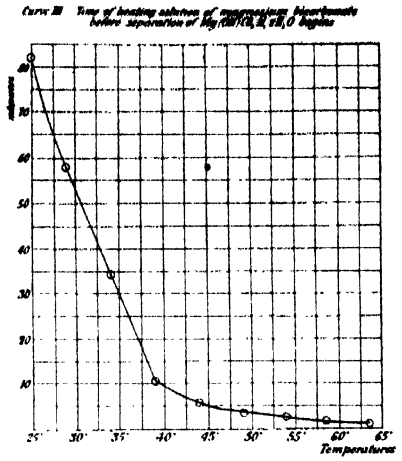
∴ $MgCO_3$ equivalent to 61·5 − 61·2 = 0·3 c.c. of acid has been precipitated,



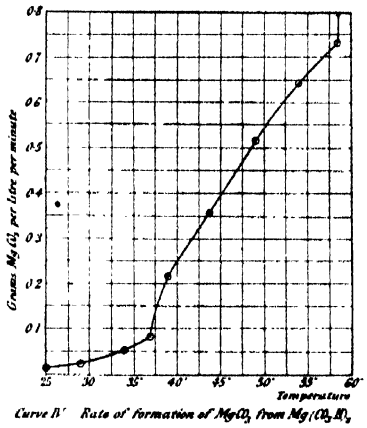
i.e. = 0·3 × 1·065 × 0·004218 = 0·00135 grm $MgCO_3$.



Whence $MgCO_3$ in solution when crystallisation began = 0·0322 + 0·0013 grm.



$Mg(CO_3H)_2$ per litre = 0·4212 × 40 = 16·85.



$MgCO_3$ " = 0·0335 × 40 = 1·34.

$$\frac{Mg(CO_3H)_2}{MgCO_3} = \frac{16{\cdot}85}{1{\cdot}34} = 12{\cdot}6.$$

*63·5	3·09	1·25	2·47

* Average of three experiments.

Table II. shows the rate at which magnesium hydroxide carbonate (calculated as $MgCO_3$) is formed from magnesium bicarbonate at different temperatures.

Example at 25° C.—Time before separation began = 82 minutes. Total $MgCO_3$ formed = 1·20 grms. per litre.

Rate of formation $= \frac{1{\cdot}20}{82} = 0{\cdot}015$ grm. $MgCO_3$ per min. per litre.

The results given in the tables are plotted in four curves.

Curve I. shows the amount of $OH.Mg.CO_3H$ in solution (calculated as $MgCO_3$) when $OH.Mg.CO_3H,2H_2O$ (the so-called trihydrate, $MgCO_3,3H_2O$) begins to separate. The curve thus represents the apparent solubility at the various temperatures of $OH.Mg.CO_3H,2H_2O$ in presence of the bicarbonate.

Curve II. gives the ratio, $\frac{Mg(CO_3H)_2}{MgCO_3}$, at the same instant for different temperatures.

Curve III. shows the time of heating required before crystals of $OH.Mg.CO_3H,2H_2O$ begin to separate from the bicarbonate solution at different temperatures.

Curve IV. shows the rate of formation of $OH.Mg.CO_3H$ from the bicarbonate.

Interpretation of results.—The crystalline products separating at all temperatures between 25° and 70° is the hydroxide carbonate dihydrate, $OH.Mg.CO_3H,2H_2O$, which is perfectly homogeneous under the microscope (Photograph I.) and never contains "basic" carbonate.

Analyses.

Separated at	Found	Ratio
I. 25°.	MgO, 29·76, CO_2, 32·71,	$\frac{CO_2}{MgO}=1·098$
II. 70°.	MgO, 29·43, CO_2, 32·46,	$\frac{CO_2}{MgO}=1·102$
III. 75°.	MgO, 29·58, CO_2, 32·07,	$=1·085$

$OH.MgCO_3,2H_2O$ requires $MgO=29·16$, $CO_2=31·79$, $H_2O=39·05$. $\frac{CO_2}{MgO}=1·090$

All three products contain slightly more MgO and CO_2 than correspond with the formula, $OH.Mg.CO_3H$, but the constancy of the ratio $\frac{CO_2}{MgO}$ shows that this is due to a slight loss of water. Von Knorre (Zeit. anorg. Chem., **1903, 34,** 260) has also observed that the finely divided "trihydrate," $MgCO_3,3H_2O$, loses a little of its water at the ordinary temperature. That actually the same crystalline variety of the salt, $OH.Mg.CO_3H,2H_2O$, separates at 70° as at 25° is apparent on examining the crystals under the microscope, both in ordinary and in polarised light. The peculiar changes in the "apparent solubility" of the carbonate seen from Curve I. to occur in the neighbourhood of 39° and 59° cannot, therefore, be attributed to the formation of different hydrates or crystalline varieties of the salt. Curve IV., on the other hand, shows that in the interval from 25° to 60°, three distinct stages can be traced in the decomposition of the bicarbonate. They are, as follows:—

Region I. 25°—37°.—The Curve I. of "apparent" solubility is in reality a curve of supersolubility; all the points on the curve represent amounts of $MgCO_3$ in solution (1·2 to 3·1 grms. per litre) far exceeding those corresponding with the solubility of the so-called trihydrate, $MgCO_3,3H_2O$, which separates. According to Auerbach (Zeit. Electrochemie, 1904, **10**, 161) the solubility of $MgCO_3,3H_2O$, expressed as $MgCO_3$, is about 0·73 grm. per litre at 25°, and diminishes as temperature rises.

It would appear that between 25° and 39° two changes are taking place, *viz.*, the following:—

$$Mg<\begin{matrix}CO_3H\\CO_3H\end{matrix}+H_2O=Mg<\begin{matrix}OH\\CO_3H\end{matrix}+H_2CO_3\ldots.\alpha^*$$

in which a comparatively soluble and, perhaps, simple hydroxide-carbonate is produced, and a second, in which the hydroxide carbonate undergoes polymerisation:

$$nMg<\begin{matrix}OH\\CO_3H\end{matrix}+Aq\rightarrow(MgOH.CO_3H,2H_2O)\ldots\beta$$

At all points, when separation begins, the solution may be regarded as saturated with $(OH.Mg.CO_3H,2H_2O)$, but not saturated with the simpler, less complex form, $OH.Mg.CO_3H$, which is being produced directly from the bicarbonate. The variation shown in Curve I. as regards the amount of $MgCO_3$ in solution at different temperatures, may be regarded as due to there being different amounts of the simple form, $OH.Mg.CO_3H$, in solution at the moment when crystals of $OH.Mg.CO_3H,2H_2O$ begin to separate. The fact that up to 37° the amount of $MgCO_3$ in solution at the moment of separation of crystals increases with temperature, may be interpreted by assuming that rise of temperature accelerates the change, α, more than it does β. Both changes occur comparatively slowly between 25° and 37°, so that the bicarbonate solution has to be heated during intervals varying from 82 to 21 mins. (see Table II.) before solid begins to separate. The gentle slope of Curve IV., between 25° and 37°, shows that in this interval the actual rate of decomposition of the bicarbonate is only slightly influenced by temperature.

Region II. 37°—58·5°.—At about 37°, a sudden change in the direction of Curve IV. occurs, showing that a new kind of decomposition of the bicarbonate is setting in; the slope is steeper, indicating an increased rate of decomposition. Curve I. shows at the same time a gradually decreasing amount of $OH.Mg.CO_3H$ in solution at the moment when crystals of $OH.Mg.CO_3H,2H_2O$ begin to separate. It would appear that the decomposition, γ, of the bicarbonate, which sets in at about 38°, produces, not the soluble form $OH.Mg.CO_3H$, but the probably more polymerised form $(OH.Mg.CO_3H,2H_2O)_n$ directly. It is difficult to realise how this occurs, but probably several molecules of the bicarbonate take part simultaneously in the action, thus:—

$$nMg(CO_3H)_2+nH_2O\rightarrow(Mg<\begin{matrix}OH\\CO_3H\end{matrix})_n,2nH_2O\ldots\gamma.$$

The low solubility of the crystals having the composition, $OH.Mg.CO_3H,2H_2O$ (*viz.*, about 0·7 grm. per litre) would point to a considerable degree of polymerisation. Between 37° and 58·5°, the three changes, α, β, and γ, are probably occurring simultaneously; the slope of the Curve IV. and the constant diminution of the amount of $MgCO_3$ in solution at the moment when crystals begin to separate (Curve I.) would, however, indicate that the change, γ, more and more predominates as the temperature is raised. A "lag" may occur in the beginning of the change, γ; this would account for the values obtained between 34° and 39° on the Curve I. If such a "lag" could be prevented, the Curve I. would probably follow the course marked by the dotted line, MN.

Region III. Above 60°.—Between 58·5° and 63·5°, another and, as it were, explosive decomposition of magnesium hydrogen carbonate sets in; the result of this seems to be the direct formation of the soluble hydroxide-carbonate, $OH.Mg.CO_3H$, for the amount of $MgCO_3$ in solution, at the moment crystals begin to separate, increases from 1·275 grm. per litre at 58·5° to 3·09 grms. per litre at 63·5°. There is an enormous increase in the rate of decomposition of the bicarbonate, Curve IV. becoming almost vertical. The velocity of the change, β, at 63·5° is sufficiently great to cause a separation of crystals of $OH.Mg.CO_3H,2H_2O$ in 1½ minutes. The changes occurring between 58·5° and 63·5° are probably—

$$Mg<\begin{matrix}CO_2.OH\\CO_3H\end{matrix}\rightarrow Mg<\begin{matrix}OH\\CO_3H\end{matrix}+CO_2\ldots\ldots\ldots\delta$$

$$nMg<\begin{matrix}OH\\CO_3H\end{matrix}+Aq\rightarrow(OH.Mg.CO_3H,2H_2O)_n\ldots\beta$$

Above 63°.—The hydrolyses, α and γ, are negligible in comparison with the decomposition δ.

Magnesium hydroxide-carbonate, $OH.Mg.CO_3H$.—The foregoing results show that the action of water on magnesium bicarbonate is initially one of partial hydrolysis, giving rise to $MgOH.CO_3H$; the actual product being the dihydrate, $OH.Mg.CO_3H,2H_2O$. This substance does not lose water when boiled with absolute alcohol (b.p., 78°) during 1½ hours; at 95° the rate of loss begins to be appreciable, and at 100° the product, $OH.Mg.CO_3H$, is obtained on heating until the weight becomes constant. Even at 110°—115° water is lost comparatively slowly; 2 grms. of $OH.Mg.CO_3H,2H_2O$ losing 25·43 per cent. (constant) of its weight in 18 hours when heated in a crucible at 110°—115°. At 125° the loss of weight occurs more rapidly, but does not (unless the heating is very prolonged*) exceed that required for the formation of $Mg(OH).CO_3H$.

At 125°, 2·000 grms. lost 26·45 per cent. (constant) in 4½ hours. Theory for loss of $2H_2O=26·04$ per cent.

Magnesium hydroxide carbonate can also be obtained from the dihydrated salt, $Mg(OH).CO_3H,2H_2O$, by boiling the latter with xylene (b.p., 136°—138°) and distilling off

* An analogy may be traced between such a hydrolysis of magnesium bicarbonate and the decomposition by water of the etherates of magnesium bromide and iodide (Menschutkin, Bull. St. Petersburg, Polyt. Inst., 1905, 4. See Abstr. Chem. Soc., 1906, i, 132); for example:

$MgI_2.2Et_2O+H_2O \rightarrow MgI.OH,2Et_2O+HI$,

$Mg(CO_2H)_2,Aq+H_2O \rightarrow Mg(OH).OO_2H,Aq+H_2CO_3$.

* Prolonged heating of $OH.Mg.CO_3H$ at 125° during several days, causes slight decomposition, accompanied by loss of water and carbon dioxide.

the water as fast as it is liberated.* For this purpose the hydrated salt (3 grms.) is boiled with purified dry xylene (450 grms.), and the latter gradually distilled from the solid, until it no longer carries water with it; the distillation is so regulated as to be continuous during 2½ hours, the amount of xylene then remaining undistilled being about 75 c.c. The last 100 c.c. of xylene passing over should be perfectly limpid and free from water. The crystals remaining, after being heated during 15 minutes in a stream of air at 130° to remove traces of xylene, gave $MgO = 39{\cdot}97$, $CO_2 = 42{\cdot}36$, $H_2O = 17{\cdot}67$ per cent.; calculated for $Mg(OH).CO_3H$, $MgO = 39{\cdot}39$, $CO_2 = 43{\cdot}06$, $H_2O = 17{\cdot}58$. The product has lost a little carbon dioxide, probably owing to slight decomposition by water; the analysis corresponds with a mixture $Mg(OH).CO_3H + 0{\cdot}030Mg(OH)_2$. Calculated: $MgO = 39{\cdot}92$, $CO_2 = 42{\cdot}27$, $H_2O = 17{\cdot}82$ per cent.

It is remarkable that the hydroxide-carbonate retains the external crystalline form of the dihydrate $OH.Mg.CO_3H.2H_2O$, from which it is prepared, either by heating in the dry state or with xylene. When examined under the microscope, however, it is seen to differ from the dihydrated salt (Photographs I. and II.) by showing striations running lengthwise along the faces and small "blowholes" from which steam was probably emitted (see Photographs III. and IV.). The hydroxide-carbonate would thus appear to be pseudomorphous with its dihydrate, but it is to be observed that the optical properties of the latter do not appear to be destroyed; the crystals of $Mg(OH).CO_3H$, when examined between crossed Nicols, appear bright against a black ground (Photograph V.); Photograph VI. shows a crystal of the dihydrate, $OH.Mg.CO_3H.2H_2O$, under similar conditions. The extinction is in both substances straight. It would appear that we are dealing with one of those cases in which loss of water exercises little influence on crystalline shape; as, for instance, in passing from $Na_2CrO_4.10H_2O$ to $Na_2CrO_4.4H_2O$ (Arzruni, Physik. Chemie der Krystall, p. 270).

II. Magnesium Carbonates.

For the peculiar properties of Engel's variety of $MgCO_3$, see Compt. rend., 1899, **129**. 598. It is easily convertible by water into $OH.Mg.CO_3H$, and therefore can be decomposed by boiling with water giving magnesium hydroxide.

Magnesite, $(MgCO_3)n$, either crystalline or massive, is not changed when boiled in a state of fine powder with water or alkaline carbonates.

Crystalline.—Original substance contained $MgO = 47{\cdot}50$ per cent. Boiled two hours with water, $MgO = 47{\cdot}31$.

Massive. Original substance contained $MgO = 49{\cdot}3$ per cent. After boiling two hours with water, $MgO = 48{\cdot}9$.

Crystalline.—Boiled two hours with $N/10$ potassium carbonate, $MgO = 47{\cdot}4$ per cent.

III. The So-called "Basic" Magnesium Carbonates.

Brill (Zeit. anorg. Chem., 1905, **45**, 275) considers that a series of seven distinct basic carbonates are formed, between the temperatures of 230° and 510°, when magnesium carbonate is heated, and attributes to each a definite dissociation temperature. The fact that he worked with a "hygroscopic" magnesium carbonate, having the composition, $MgCO_3.\frac{1}{2}H_2O$, however, deprives his results of real significance as examples of the "dissociation" of magnesium carbonate; the presence of water profoundly modifies the decomposition of magnesium carbonate. Brill's material began (owing to the presence of water) to "dissociate" at 230°. Magnesite does not lose water until 405° (Anderson), but magnesium hydroxide carbonate is known to decompose, losing carbon dioxide, considerably below 300°.

Method of analysis of the so-called basic carbonates.—The method adopted was to heat about 0·3—0·5 grm. of the carbonate, contained in a platinum boat, very gradually by means of a Ramsay burner, in a Jena glass combustion tube, 9 ins. by ½ in., through which a current of air was slowly passed. The water and carbon dioxide formed were absorbed, respectively, in a weighed calcium chloride tube and Wetzel potash bulb, as in an ordinary combustion. The decomposition was usually complete within 20—40 minutes; during the last 10 minutes, the largest possible flame obtainable with the Ramsay burner was used, and the decomposition was considered to be at an end when, on stopping the current of air, a bubble of gas did not pass forward into the bulbs during about 30 seconds. The percentage of magnesium oxide was ascertained by igniting, to constant weight, in a muffle furnace, about 0·5 grm. of the carbonate. A check on the accuracy of the analyses was obtained by ascertaining whether the sum of the percentages amounted to 100. If the substance analysed was at all hygroscopic and, therefore, increased in weight whilst being weighed in an open boat, the method was slightly modified. The substance was weighed from a small corked glass tube, about ¼ in. diameter, directly into the combustion tube, being poured against a plug of asbestos placed about 1½ in. from the end connected with the weighed calcium chloride tube; the combustion tube was then gently shaken so as to distribute the powder evenly and ensure that the whole of it got heated. Before each analysis, it is, of course, necessary to pass dry air through the heated tube to expel all moisture.

Formation of the salt, $Mg.OH.CO_3H.2H_2O$, *by the action of sodium carbonate on magnesium sulphate.*—Cold solutions of equivalent quantities of sodium carbonate and magnesium sulphate, each dissolved in 15 parts of water, were mixed, and the "basic" precipitate first formed left with the mother liquor. After four days, the precipitate was entirely crystalline, and contained $MgO = 29{\cdot}73$ per cent. (air dried.) The mother liquor after standing for three months gave a further crop of needles, which on analysis gave $MgO = 29{\cdot}25$. Calculated for $Mg(OH).CO_3H.2H_2O$, $MgO = 29{\cdot}16$. The experiment clearly shows that a "basic carbonate" cannot be produced by the decomposition of the hydroxide-carbonate by water at the ordinary temperature; the crystals separated from the mother liquor were in contact with water containing a slight excess of alkaline carbonate during three months, and yet contained magnesia and carbon dioxide in the ratio corresponding with a normal carbonate.

The following experiment shows that pure water, free from alkali, is practically without action on magnesium hydroxide-carbonate dihydrate at the ordinary temperature. About 1 grm. of the specially purified material was left at 18° for three weeks with 150 c.c. of distilled water in a well-stoppered Jena flask; at the end of this time the solution was perfectly clear and the crystals transparent and unchanged. After about one month, however, the crystals began to stick to the glass and to show change where they were in contact with it; a thin film of hydroxide began to form over them. The decomposition in contact with the glass is perhaps caused by the glass itself.

Effect of boiling the salt, $OH.Mg.CO_3H.2H_2O$, *with water.*—5 grms. of the crystalline salt, consisting of white needles, was boiled with 325 c.c. of water in a Jena flask during 15 minutes, about a third of the product being then separated, dried in the air, and analysed,=Product I. The remainder of the solid was then boiled with the same liquid during another 15 minutes, and half of it separated and dried,=Product II. The remaining portion of the solid was boiled with liquid during 30 minutes, the volume being kept fairly constant by adding water as required,=Product III. Product I. represents the effect of boiling $OH.MgCO_3H.2H_2O$ with water during 15 minutes, Product II. of boiling during 30 minutes, and Product III. the result of boiling with water during one hour. The following table summarises the results. All the substances were air dried.

* If the water is not removed in this way, it attacks the hydroxide-carbonate and gives rise to a product containing much magnesium hydroxide, similar in composition to that obtained by boiling the hydrated salt with a large quantity of water.

TABLE III.

Product.	Time in mins.	Concentrated $MgCO_3$ per litre expressed as $MgCO_3$	Composition per cent. MgO	CO_2	H_2O	Formula.	Mixture of.	$\frac{H_2O}{CO_2}$ found.	$\frac{H_2O}{CO_2}$ calculated.
I.	15	5·5	39·76	35·16	25·12	$MgCO_3$, 0·234 $Mg(OH)_2$, 1·51H_2O	* 1·1 $Mg(OH)CO_3H$, $2H_2O$; 3·16 $Mg(OH).CO_3H$; 1·0 $Mg(OH)_2$	8·38	8·32
II.	30	3·7	41·17	35·28	23·62	$MgCO_3$, 0·270 $Mg(OH)_2$, 1·365 H_2O	† 0·70 $Mg(OH)CO_3H$, $2H_2O$; 3·0 $Mg(OH)CO_3H$; 1·0 $Mg(OH)_2$	8·06	8·00
III.	60	1·8	41·45	35·40	23·18	$MgCO_3$, 0·276 $Mg(OH)_2$, 1·323 H_2O	‡ 0·58 $Mg(OH).CO_3H.2H_2O$; 3·05 $Mg(OH).CO_3H$; $Mg(OH)_2$	8·07	8·10

* Calculated: MgO = 39·74 CO_2 = 35·08 H_2O – 25.18.
† Calculated: MgO = 41.03 CO_2 = 35.20 H_2O – 23.76.
‡ Calculated: MgO = 41.43 CO_2 = 35.42 H_2O = 23.15.

The products, when examined under the microscope, were seen to be mixtures (compare Photographs VII. and VIII.). They may be considered as formed by the two following actions:

A. $Mg(OH)CO_3H,2H_2O \rightarrow Mg(OH)CO_3H + 2H_2O$ *Dehydration.*

B. $Mg(OH)CO_3H + H_2O \rightarrow Mg(OH)_2 + H_2CO_3$ *Hydrolysis.*

An easy calculation shows that the nature of the products I. II., and III. can be explained in a simple manner by such a hypothesis.

In the original substance $OH.MgCO_3H,2H_2O$,

	CO_2	H_2O
1 grm. MgO is associated with	1·0902 grm.	and 1·3390

In Product I.,

1 grm. MgO is associated with	0·8841 grm.	and 0·6317
	0·2061	0·7073

Thus, in the formation of the "basic carbonate" I. from the original substance,

1 grm. MgO loses 0·2061 grm. CO_2 and 0·7073 grm. H_2O.

Ratio of loss of water to loss of carbon dioxide $= \frac{0·7073}{0·2061} = 3·43$.

Mol ratio, $\frac{\text{loss of } H_2O}{\text{loss } CO_2} = 3·43 \times \frac{44}{18·02} = 8·38$.

Thus, in forming the Product I. from the original material 8·38 mols. of water are lost for every 1 mol. of CO_2 expelled.

Similarly, in forming Products II. and III. from the same substance the ratio of $\frac{\text{loss of } H_2O}{\text{loss of } CO_2}$ is found to be 8·06 and 8·07 respectively (see table).

It is only necessary to assume that the action, A (dehydration), takes place about 8¼ times as rapidly as change B (hydrolysis), to explain the approximately constant character of the ratio of the loss of water to loss of carbon dioxide. The change, B, takes place more slowly than change, A, owing to the comparatively small solubility of the original material.

The composition of substances, I., II., and III., is shown in the eighth column to agree with this view; Product I. can easily be calculated to be a mixture of 1·1 mols. $OH.Mg.CO_3H,2H_2O$ (unchanged material), 3·16 mols. $Mg(OH).CO_3H$, and 1·0 mol. $Mg(OH)_2$, and similarly the composition of II. and III. agrees with that of the mixtures given in the table. If in the case of I., it be supposed that 5·26 mols. of $Mg(OH).CO_3H,2H_2O$ are started with, and 4·16 of these undergo change according to A, 1·00 mols. of the hydroxide-carbonate formed undergoing change in the sense of B, we obtain a theoretical ratio of $\frac{\text{loss of water}}{\text{loss of } CO_2} = \frac{8·32}{1} = 8·32$

The values calculated for the Products II., and III., assuming them to be mixtures formed in a similar manner, in the last column of the table, agree closely with those calculated from the composition given in column 8.

Progressive decomposition of magnesium hydrogen carbonate in solution, between temperatures of 80° and 100°.—1200 c.c. of a solution of magnesium hydrogen carbonate (free from alkali, and containing 11·07 grms. $MgCO_3$ per litre) was gradually heated to a temperature of 78°. During the heating between 65° and 78° a crystalline precipitate separated in quantity. The times of heating were seven minutes to raise from 65° to 70°, five minutes to raise from 70° to 78°; then left to cool to 70°; time of cooling from 78° to 70° = 18 minutes.

Precipitate = α, weight, air dried, = 11·0 grms.; under microscope, entirely crystalline (see Photograph 1.).

The mother liquor (containing about 6·7 grms. $MgCO_3$ per litre) was then heated during 20 minutes at 85°—90°. Precipitate = β, weight, air dried, = 2·5 grms. a light powder, only partly crystalline under microscope (see Photographs VII. and VIII.).

Mother liquor from β (containing, roughly, 3·0 grms. $MgCO_3$ per litre) boiled at 100° during 15 minutes. Precipitate = γ, weight 3·1 grms. – somewhat more compact than β, and only very slightly crystalline.

Mother liquor from γ, containing, as shown by a titration, 0·26 grm. $MgCO_3$ per litre, boiled 65 minutes. Precipitate = δ, formed only slowly, gelatinous when wet, horny when dry, and resembling magnesium hydroxide. Dried in air only very slowly. Weight, dry, 0·15 grm.

The following table gives a summary of the result and indicates the nature of the precipitates:—

TABLE IV.

Precipitate.	$MgCO_3$ per litre in solution	Temp. of heating	Time of heating.	Composition, expressed by formula.*	Mixture of	Found Mol ratio, $\frac{\text{loss } H_2O}{\text{loss } CO_2}$	Mol. ratio, $\frac{\text{loss } H_2O}{\text{loss } CO_2}$ calculated for mixture.
α	11·1	65°–78°	30 min	$MgCO_3,3H_2O$			
β	5·5	85°–90°	20 „	$MgCO_3,0·208\ Mg(OH)_2,1·04H_2O$	1·50 mols $Mg(OH)CO_3H$, $2H_2O$; 3·30 mols. $Mg(OH)CO_3H$; 1·00 mols $Mg(OH)_2$	8·55	8·60
γ	3·0	100°	15 „	$MgCO_3,0·246\ Mg(OH)_2,1·44\ H_2O$	0·90 $Mg(OH)CO_3H$, $2H_2O$; 3·10 $Mg(OH)CO_3H$; 1·00 $Mg(OH)_2$	8·33	8·20
δ	0·26	100°	60 „	$Mg(OH)_2,0·143\ MgCO_3,0·81\ H_2O$			

* The absorption or imbibition of benzene by magnesium hydroxide is very striking; it makes the density of the latter determined in benzene appear considerably greater than that determined in water, which is not absorbed by the dried hydroxide.
Relative density of magnesium hydroxide at 25° (25°, determined by displacement of water = 2·35.
Relative density, referred to water at 25°/25°, determined by displacement of benzene = 2·58.

* *Analyses.*—α. $MgO = 29.20$; $CO_2 = 46.40$; $H_2O = 24.40$; total 100·26; calculated for mixture given:—$MgO = 29.16$; $CO_2 = 46.70$; $H_2O = 24.40$.

β. $MgO = 38.77$; $CO_2 = 34.99$; $H_2O = 26.50$; total 100·26; calculated for mixture:—$MgO = 38.74$; $CO_2 = 34.97$; $H_2O = 26.26$.

γ. $MgO = 40.29$; $CO_2 = 35.21$; $H_2O = 24.39$; total 100·08; calculated for mixture given:—$MgO = 40.35$; $CO_2 = 35.15$; $H_2O = 24.50$.

δ. $MgO = 60.75$; $CO_2 = 8.27$.

Photographs VII. and VIII. of the precipitate, β, show plainly that it is a mixture; in Photograph VII. β is mounted in glycerin jelly, and in Photograph VIII. (more highly magnified) in Canada balsam. The large crystals consist of the unchanged salt, $OH.MgCO_3H,2H_2O$, or of the hydroxide carbonate, $OH.MgCO_3H$; the opaque masses in Photograph VIII. consist of amorphous magnesium hydroxide adhering to and encrusting crystals of the hydroxide-carbonate. On adding benzene to the Canada balsam the magnesium hydroxide absorbs it and becomes transparent * and the crystals of the hydroxide-carbonate are thus rendered plainly visible. Glycerin jelly serves the same purpose to some extent, but does not render the hydroxide so transparent.

The decomposition of *magnesium bicarbonate* by water, between 65° and 78°, gives the salt, $Mg(OH)CO_3H,2H_2O$, (*a*)' alone. The products, β and γ, are formed by the decomposition by water of crystalline hydroxide-carbonate dihydrate, $Mg(OH).CO_2H,2H_2O$, initially precipitated; that this is so and that the decomposition proceeds in the manner explained on p. 796, is shown by the identity of the number expressing the mol. ratio, $\frac{\text{loss } H_2O}{\text{loss } CO_2}$, calculated for the formation of β and γ from this salt, with the constant found for the decomposition of the crystalline $OH.MgCO_3H,2H_2O$. The following table shows this:—

TABLE V.

Decomposition of magnesium hydrogen carbonate.		Decomposition of solid $Mg(OH).CO_3H,2H_2O$.	
$MgCO_3$ per litre of water.	Ratio found for loss H_2O/loss CO_2.	$MgCO_3$ per litre of water.	Ratio found for loss H_2O/loss CO_2.
5·5	8·55	5·5	8·38
3·0	8·33	3·7	8·06
		1·8	8·07

The values found with the solid $Mg(OH)CO_3H,2H_2O$ are slightly lower than with the bicarbonate solution at corresponding concentrations; this is perhaps due to the presence, in the latter case, of carbon dioxide in solution retarding the change,—

$$Mg(OH)CO_3H + H_2O = Mg(OH)_2 + H_2CO_3$$

according to the law of mass action. In both cases, the value of the ratio diminishes as the concentration of the carbonate diminishes, that is, as the proportion of water *increases*; an increase of dilution favouring hydrolysis and loss of carbon dioxide at the expense of the decomposition by dehydration.

The product, δ, probably consists of magnesium hydroxide which has taken up a little carbon dioxide from the air during the long exposure required for the gelatinous precipitate to dry; its appearance and the following experiments support this view. Magnesium hydroxide-precipitated from magnesium sulphate solution by potassium hydroxide, after draining on biscuit ware and drying rapidly at 120°—130°, was found to contain 68·44 per cent. magnesia, and to be practically free from carbon dioxide ($Mg(OH)_2$ requires $MgO = 69.1$ per cent.). When allowed to dry in the air the product contained $MgO = 67.75$, $CO_2 = 8.51$ per cent. The amount of carbon dioxide taken up agrees closely with that present in δ. The solution from which α was formed, did not contain sufficient magnesium carbonate for either of the compounds of either series, $Mg(OH)CO_3H$ or $Mg(OH)CO_3H,2H_2O$, to separate in the ordinary course of the latter's formation (about 0·20 grm. $MgCO_3$ per litre at 100°); and from precipitates that can therefore be formed on heating a magnesium hydroxide formed according to the equation,—

$$Mg(OH)CO_3H + H_2O = Mg(OH)_2 + H_2O + CO_2$$

In the experiments made by boiling the crystalline salt, $OHMgCO_3H,2H_2O$, with water, it might appear, at first sight, from the similarity of Products II. and III. (Table III.), that a definite basic carbonate was being formed. During the first 15 minutes' heating with water, the salt undergoes much more decomposition than occurs during the next 15 minutes (Product II.), whilst there is very little change at all during the next 30 minutes (Product III.). An explanation of the apparent equilibrium set up is at once given by considering Photograph VIII. A film of magnesium hydroxide is deposited on the crystals of the original salt and of the derived salt, $OHMgCO_3H$, during the earlier heating, and thus arrests the action by preventing contact with water. The mixed character of the basic carbonates of magnesium precludes, as already explained on pp. 789, 790, the acceptance of the existence of definite basic salts.

The exact composition of the product obtained after boiling a solution of magnesium bicarbonate depends entirely on the conditions, such as the original concentration and rate of heating, which determine the fineness of the initially precipitated $OH.Mg.CO_3H,2H_2O$. Thus, whilst in the foregoing experiment γ, with an original concentration of the bicarbonate solution of 3·3 grms. $MgCO_3$ per litre, a precipitate having the composition $MgCO_3,0·246Mg(OH)_2.1·44H_2O$, was obtained, a solution of the bicarbonate, containing 11·2 grms. $MgCO_3$ per litre, gave, after boiling (see p. 798) for one hour, a product, $MgCO_3.0·319Mg(OH)_2.1·20H_2O$. In the former case the ratio, $MgCO_3 : Mg(OH)_2$, is nearly 4 : 1; in the second case, approximately 3 : 1. The approximation in composition to simple formulæ is in such cases deceptive.

IV.—Decomposition of Magnesium Acidium Carbonates in Aqueous Solution at 100°.

Decomposition of the salt, $Mg(CO_3H)CO_3Na$, by water at 100°.—To 100 c.c. of a solution of magnesium bicarbonate containing 11·07 grms. $MgCO_3$ per litre, 121 c.c. of a decinormal solution of sodium hydroxide and 100 c.c. of water was added. No precipitate was formed, and the solution contained 3·3 grms. $MgCO_3$ in the form of $Mg(CO_3H)CO_3Na$ per litre. On warming to 60°, minute well-defined crystals of the salt, $Mg(OH)CO_3H,2H_2O$, began to separate. The liquid was raised to the boiling-point, kept in active ebullition for one hour, the product filtered, dried in a vacuum desiccator and analysed. Two separate preparations gave—

(*a*) $MgO = 43·58$ $CO_2 = 35·75$ $H_2O = 21·04$. Total, 100·37.

(*b*) $MgO = 42·83$ $CO_2 = 35·73$ $H_2O = 21·43$. Total, 99·99.

Mean, $MgO = 43·20$ $CO_2 = 35·74$ $H_2O = 21·24$,

corresponding with the composition,—

$$MgCO_3,0·319\ Mg(OH)_2,1·13H_2O.$$

The product is identical in composition with that formed on boiling a solution of magnesium bicarbonate with water for the same time, with similar precautions (see p. 798). It has been formed, no doubt, by the decomposing action of water on the salt, $OH.Mg.CO_3H,2H_2O$, initially precipitated, the magnesium hydrogen carbonate present in solution exercising no influence.

Behaviour of the disodium salt, $Mg(CO_3Na)_2$, when boiled with water.—To 100 c.c. of the same solution of magnesium bicarbonate was added 27·1 c.c. of N/10 sodium hydroxide (*i.e.*, 2 mols., NaOH); no precipitate was at first formed, but after 25 c.c. of the alkali had been added a faint opalescence appeared; on standing, a slight flocculent precipitate began to separate. The liquid was boiled for one hour. The product was gelatinous, resembling precipitated magnesium hydroxide. It was obtained on a tile in a vacuum over

left for four days in a vacuum desiccator.

Analysis. $MgO = 29.16$, $CO_2 = 35.38$, $H_2O = 22.79$. Total, 100·33. This agrees with the formula $Mg(OH)_2,0{\cdot}33MgCO_3,0{\cdot}75H_2O$, and indicates that the decomposition of magnesium bicarbonate; this decomposition of the salt $Mg(OCO_2Na)_2$ with water at 100° gives, therefore, about 2 mols. of $Mg(OH)_2$ for every molecule of $OH.Mg.CO_3H$ produced.

Decomposition of magnesium hydrogen carbonate by excess of sodium hydroxide.—To 58 c.c. of a solution of magnesium hydrogen carbonate, containing 20·1 grms., $MgCO_3$ per litre, 410 c.c. of *N*/10 sodium hydroxide solution (*i.e.*, $2NaOH$) was added; the amount present was, therefore, 2·8 grms. $MgCO_3$ per litre of liquid, *i.e.*, nearly the same as in the two previous experiments. The liquid was boiled for one hour. The product was slightly gelatinous and difficult to filter; it was drained on a tile and after drying as in the preceding experiment in a vacuum desiccator, analysed:—Found, $MgO = 42{\cdot}42$, $CO_2 = 5{\cdot}75$, $H_2O = 27{\cdot}00$. Total, 100·06. Composition = $Mg(OH)_2,0{\cdot}08MgCO_3$.

The product here is almost entirely magnesium hydroxide. An excess of alkali thus favours the hydrolysis, $Mg(CO_3Na)_2 + 2HOH = Mg(OH)_2 + 2NaHCO_3$, at the expense of the decomposition giving hydroxide-carbonate.

Decomposition of magnesium bicarbonate by water, free from traces of alkali.—The product obtained when magnesium bicarbonate is boiled with water (Product γ, Table IV.) is so similar in composition to that formed by decomposing (p. 797) the same substance in presence of ½ mol. of sodium hydroxide, that the question arises whether the formation of magnesium hydroxide from the bicarbonate or the salt $OH.Mg.CO_3H,2H_2O$ is not due to the intermediate production of the salt $Mg(CO_3H)CO_3Na$, owing to the presence of traces of alkali removed from the glass or present in the original solution. A solution of magnesium bicarbonate prepared from ordinary pure magnesium carbonate, which has been repeatedly boiled with large quantities of water, always shows an intense sodium flame when heated on a platinum wire. By alternately dissolving the carbonate, however, in water containing carbon dioxide and decomposing the solution so obtained, as explained on page 791, a solution of the bicarbonate may be ultimately obtained which is absolutely free from alkali. A large platinum bottle having a capacity of 2 litres was used throughout the preparation, and the water prepared by the aid of a Bousfield still, having a conductivity of 2·0 gemmhos at 25°. The bicarbonate, ultimately obtained, contained 19·7 grms. of $MgCO_3$ per litre and did not show a sodium flame when heated on a platinum wire. Fifty-seven c.c. of this solution diluted with 43 c.c. of the conductivity water, giving a concentration of 11·2 grms. $MgCO_3$ per litre, was boiled in a platinum flask of a capacity of 300 c.c., fitted with a platinum condenser-tube, round which steam circulated in a jacket. The product was collected, dried for several days in a vacuum desiccator, and analysed:—

$MgO = 29{\cdot}33$, $CO_2 = 35{\cdot}38$, $H_2O = 22{\cdot}02$. Total, 100·23. Composition = $Mg(OH)_2,0{\cdot}31MgCO_3,1{\cdot}20H_2O$.

The product is almost identical in composition with that obtained in the experiment when $1NaOH$ was present ($MgO = 29{\cdot}20$, $CO_2 = 35{\cdot}74$, $H_2O = 21{\cdot}24$). There can be no doubt, therefore, that water at 100° will of itself decompose the salt, $OH.Mg.CO_3H,2H_2O$, and that in both cases the product is formed by the decomposition of this salt by water.

In conclusion, I take great pleasure in acknowledging my indebtedness to Prof. Armstrong for much valuable criticism, to Mr. Geo. Matthey, F.R.S., for the loan of platinum apparatus, and to Mr. R. Whymper for his assistance in preparing the magnesium hydroxide.

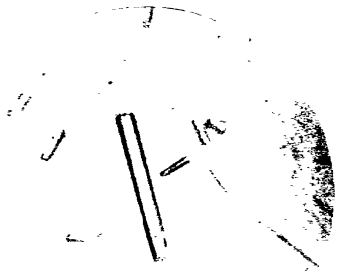
PROF. A. G. GREEN IN THE CHAIR.

A METHOD FOR THE EXAMINATION OF MARINE OILS.—PART I.

Contribution from the Leather Industries Laboratory of the University of Leeds.



BY H. R. PROCTER AND H. G. BENNETT.

It is well known that the investigation and analysis of oils is attended with considerable difficulty on account of their being mixtures of substances which are chemically very similar. The oil chemist is therefore compelled to fall back upon the determination of various "values" and constants, often of an empirical nature, and obtained by following analytical processes under certain definite conditions. One of the most important of these is the iodine value, which, being the percentage of iodine absorbed by the oil, gives some knowledge of its unsaturated constituents, and is practically a measure of the number of "double-bonds" present. This, however, yields little information as to the nature of these compounds, and we have no means of telling, for example, whether the iodine value is due to the presence of a fairly large quantity of the glyceride of an acid with one double-bond, or is accounted for by a comparatively small quantity of the glyceride of an acid with several double-bonds. Various attempts have been made to gain further information in this direction, notably by Hehner and Mitchell ("Analyst," 1898, 313) whose "hexabromide test" is based upon the differences in solubility of the bromination glycerides in ether, and of the brominated fatty acids in acetic acid, those compounds with the higher percentage of bromine being much more insoluble. Quantitative determinations of the yield of "hexabromides" from various oils have also been attempted, and the work was supplemented to some extent by Farnsteiner, who investigated more closely the "tetrabromides" of vegetable oils.

The present work is an application of this principle of different solubility to the marine oils—information as to these being most needed in the institution from which the research comes. It is well known that these oils are often adulterated by admixture with other marine oils of inferior quality and price, and that, unfortunately, it is usually quite impossible to tell by any known test whether this has been done, and to what extent. Hence, one of the principal hopes of the authors was that in the investigation of the more highly unsaturated glycerides of these oils such striking differences might be observed in the quantity, as revealed by the percentage yield of "hexabromides," as would serve not only for their identification but also for the detection of adulteration.

This hope was encouraged by the results already obtained, a summary of which is given in table on p. 79[illegible]

As far as the glycerides are concerned, the method of Hehner and Mitchell as it stands, is open to several objections, not the least obvious being their method of adding bromine until a permanent coloration is first obtained, and then allowing it to stand three hours. Evidently if there is to be complete bromination, it will be necessary to add enough bromine to leave some unabsorbed at the end of three hours. Moreover, as a test in which to do a quantitative bromination, ether is a peculiar choice. Its hygroscopic nature, its [illegible]

sufficient phenol was added to cause the disappearance of the colour due to the excess of bromine. The results were fairly satisfactory, being as follows:—

*Möller's Cod Liver Oil.**

1 .. 38·9 2 .. 38·2

Brown cod oil.		*Bromine percentage.*
1. 58·3	.....	59·1
2. 60·5	.....	57·7
3. 59·1	.....	58·7
4. 59·1	.....	58·3

It seemed of interest now to investigate somewhat the nature of the precipitate and to find the amount of bromine it contained. A standard solution of bromine in carbon tetrachloride was made, and a definite quantity—insufficient for complete bromination—was added to a carbon tetrachloride solution of cod oil, and after the disappearance of the bromide, the bromides were hydrolysed on the water-bath by the action of alcoholic potash for three hours. This not only saponifies the glyceride, but removes the bromine as potassium bromide, leaving the alkali salts of the hydroxy fatty acids. The products were now washed into a calibrated flask, made distinctly acid by formic acid, the excess of it neutralised by the addition of some magnesium oxide, and the solution made up to the mark with distilled water. The insoluble portions were filtered off, their volume being inappreciable, and the amount of potassium bromide estimated in aliquot portions of the filtrate, by means of N/10-silver nitrate solution, using three drops of 10 per cent. potassium chromate solution as indicator. This method was found to be accurate, and hence was applied to the precipitates obtained from the brown cod oil, above. The results are given in the column adjoining the yield of bromine.

Accepting the statement of Dieterich that the mean molecular weight of the acids of cod oil is approximately 275, the "hexabromide" of a triglyceride would have 62·5 per cent. of bromine, a "tetrabromide" 52·5 per cent. of bromide, and a "dibromide" 35·8 per cent., and hence it will be seen that the above precipitates must either be the bromide of a mixed glyceride, or a hexabromide precipitate with lower bromides mixed with it, or both, the variations noticed making the last two explanations the more probable. It will be noticed, too, that where the yield of bromides is greatest, the bromine percentage is least, and *vice versâ*. This bears out the idea that we are dealing with mixtures of bromides, those containing the most bromine being the most insoluble.

An experiment was now made, using a larger quantity of oil, brominating in carbon tetrachloride as usual, and removing the excess of bromine by phenol, and then precipitating the bromides gradually by alcohol, filtering off each fraction separately, washing, drying, weighing, and estimating the bromine in each fraction.

9·853 grms. of brown cod oil were dissolved in 200 c.c. of carbon tetrachloride. After the bromination, the solution was slightly turbid, but nothing could be filtered off.

50 c.c. of alcohol were added—again the filter retained nothing. 50 c.c. of alcohol were added again—large precipitate. (Fraction 1.)

To the filtrate from (1) 100 c.c. more alcohol were added, but nothing could be filtered; 25 c.c. more alcohol however, precipitated an oil which was filtered off with difficulty. (Fraction 2.)

To the filtrate, 75 c.c. more alcohol were added and more oil was precipitated. (Fraction 3.) 100 c.c. of alcohol added to the filtrate precipitated still more oil. (Fraction 4.) No further precipitate was obtained. The total yield was 133·6 per cent., and the weights of each fraction and its percentage of bromine are given as follows:—

	grms.	per cent. bromine.
(1)	9·6974	containing 60·3
(2)	1·3883	containing 53·7
(3)	0·6449	containing 54·6
(4)	1·2125	containing 33·1

* It will be noticed, perhaps, as curious that Möller's cod—which is supposed to be unoxidised—should give a lower result than an ordinary brown cod. This fact was also confirmed by the method as modified later, but the authors do not as yet attempt to explain it.

Keeping still to the assumption of 275 as a mean molecular weight for the acids, and excluding the possibility of mixed glycerides, we see that, roughly speaking, (1) is a "hexabromide" mixed with some tetrabromide, (2) and (3) are tetrabromides mixed with some hexabromide, and (4) is dibromide mixed with some saturated oil. It may be mentioned that part of (1) was dissolved in carbon tetrachloride and fractionated further, and two fractions were obtained which gave over 70 per cent. of bromine; *i.e.*, were "octabromides"—corresponding to the triglycerides of an acid with four double-bonds.

It seemed evident from this experiment that it would be better in the quantitative work to add less alcohol, and so exclude more tetrabromide (which is shown above to be an oil), and thus render the filtration more easily workable. This conclusion was strongly confirmed by a quantitative experiment, in which the precipitate was left 18 hours before filtration, and was then found to be very oily, difficult to filter, and to give a bromide yield of 79·6 per cent., thus showing the tetrabromide to be really insoluble in the mixture of one volume of carbon tetrachloride and two volumes alcohol, though only very gradually precipitated.

The method of drying in air was also dispensed with, for the simple reason that it was necessary to weigh the precipitate and paper under the same conditions of atmospheric humidity as when the paper was tared, and this was not always possible. As heat has been shown to decompose the precipitate, it is necessary to have an arbitrarily fixed time for heating, and as it may be necessary to estimate the bromine in the precipitate, this time should obviously be at a minimum, so that the precipitate may be as little decomposed as possible. Henceforth, therefore, the precipitates were dried in air, and then heated for a quarter of an hour in the steam oven, which was quite sufficient to get atmospheric moisture out of the filter paper.

Again, in view of the expense of both absolute alcohol and carbon tetrachloride, and from the standpoint of quick working, it seemed desirable to make some reduction in the quantities used. Hence, the method was modified as follows:—

Cod oil =0·4 grm. (approximately), is weighed out into a small tared flask, and 10 c.c. carbon tetrachloride added, and 12 drops of bromine, the mixture being kept cool for three hours in running water. Remove the excess of bromine by adding 10 c.c. of carbon tetrachloride containing 0·075 grm. of phenol, and add 20 c.c. of absolute alcohol gradually, with constant stirring. Filter, and allow to drain, wash with 50 c.c. absolute alcohol,* dry in air, place in a weighing bottle which has been first tared along with the paper, and heat in steam oven for a quarter of an hour, cool in a desiccator, and weigh. The bromine should be dropped from a tap funnel at a rate convenient for counting, and, with duplicate experiments, should drop at the same rate. It was proved, by dropping into excess of potassium iodide, and titrating with thiosulphate, that this gives very approximately the same quantity of bromine. For any given oil it is necessary to keep the weight taken very nearly the same, for, if too little be taken, more bromine will be left over than will be debrominated by the small quantity of phenol added, and, if too much be taken, there may be no bromine left in excess at the end of the three hours. With these precautions and some care, results varying within 1 per cent. can easily be obtained. This percentage yield of bromides is called the "*Bromide value.*"

E.g., *Brown cod oil.* (Iodine value, 150·7.)

Bromide value.		Bromine percentage.
1. 60·9	.....	65·7
2. 60·0	.....	63·3
3. 60·4	.....	63·5
4. 60·8	.....	63·7

As the quantities of liquids and the amount of bromine and phenol which are added are made definite according to the above method, in applying the process to other oils, it will be obviously necessary to take quantities which will

* This absolute alcohol after standing overnight with potassium hydrate and distilling twice over potash, can be used again for the same purpose.

give in solution about the same amount of unsaturation, and hence leave about the same amount of bromine unabsorbed. These quantities will evidently be obtained by making them inversely proportional to the iodine value of the oil.

These precipitates do not always filter off very well at first, and it is necessary then to pass the liquor through until it filters quite clearly. Usually this occurs before the liquor has been passed through once, and it is only in the case of those oils which give a very small yield that the filtration is really difficult. It will be noticed, too, that in these cases of awkward filtration not only is the yield small, but also the amount of bromine in the precipitate is lower than usual, indicating that the difficulty is partly due to the presence of greater quantities of the lower bromides. In all cases it is desirable from the point of view both of accuracy and rapidity of work to keep the filter paper full, when once the filtration is started.

The method was now applied to various vegetable and animal oils.

Castor oil was turbid slightly before the addition of bromine, rather more so after bromination, but this disappeared on the addition of alcohol. Olive oil, sesamé oil, and cotton-seed oil gave no precipitate. Rape oil gave a very small precipitate, and lard oil a trace of precipitate. This confirms to some extent the observations of Farnsteiner.

The method was also applied to the fatty acids obtained from a brown cod oil. The bromination produced a dark brown precipitate which was apparently little changed in quantity by the addition of alcohol. Bromide value—10·4.

This shows that, although the free acids do not give the same results as the glyceride, they do give a precipitate, and hence we can conclude that an oil of high acid value will not have its bromide value seriously affected. The method was now applied in duplicate to the various marine oils, and the results are given in the table below.

It will be noticed that where the yield was small, it was sometimes necessary to add together the precipitates obtained in the duplicate experiments in order to estimate the bromine. The iodine value of each oil is given, and as this is the percentage of iodine absorbed by the oil, one can get, by a simple calculation, the "bromine value" of each oil. From this figure and the weight of oil taken in the experiment, the total amount of bromine absorbed by this amount of oil is easily obtained, and as the weight of bromine in the precipitate is determined during the estimation of its percentage in the precipitate, one can thus see how much of the total bromine is absorbed by the glycerides which give the precipitate, and how much by those which do not. This distribution is best expressed in the percentage of the total bromine absorbed, and is given as such in the table below.

Example: 0·4138 grm. of cod oil gave 0·2502 grm. of precipitate containing 0·1591 grm. of bromine. From the bromine value we see that 0·4138 grm. of oil absorbs 0·3927 grm. of bromine. Hence the percentage of total bromine absorbed, which is taken up by the glycerides giving precipitates,

$$= \frac{0{\cdot}1591 \times 100}{0{\cdot}3927} = 40{\cdot}5$$

Assuming that the formation of these bromides is due merely to the addition of bromine to the unsaturated linkages in the oils, it is clear that by subtracting the weight of bromine found in the precipitate, from the weight of the precipitate taken we get the weight of the glycerides which gave the precipitate, and hence it is simple to calculate the bromine value of these glycerides, and by the use of the factor 127/80 to obtain also, therefore, the iodine value of the more highly unsaturated portions of the oil. If these portions are the most readily oxidisable, this figure may be of even more value than the iodine value of the oil for indicating its quality and its state of oxidation. This is illustrated by the first two oils in the table.

It will be next necessary to make investigations of the constants of a series of oils in which the range of variation of the bromide value is observed, especially in relation to the iodine value, for it is clear that unless this range is determined the method will be of no great practical use in the detection of adulteration. It may be observed, however, that the figures for seal oil and the fish oils seem promising, the bromide values being much lower, and it is the hope of the authors that, although the iodine value of an oil is "adjusted," it will be impossible to adjust, at the same time, the bromide value, and the distribution of the total bromine absorbed.

The process is empiric, but the oil chemist is forced to rely at present upon such processes. That this is undesirable, all will admit, but nothing perfectly satisfactory can be obtained until oil chemists know what they are analysing. This can only be realised by patient investigation as to the exact chemical nature of the glycerides and fatty acids in particular oils. The authors believe that the above work is, at any rate, one step in this direction.

Oil.	Iodine value.	Bromine value (by calculation).	Bromide value.	Percentage of bromine in precipitate.	Percentage of the total bromine absorbed, which is taken up by the glycerides giving the precipitate.	Mean iodine value of glycerides giving precipitate.

ENGLISH PATENTS.

Straining or filtering water and other liquids; Apparatus for ——. E. Gobbi, Paris. Eng. Pat. 83, Jan. 1, 1906. Under Int. Conv., Jan. 11, 1905.

A NUMBER of pairs of dished plates of "non-permeable" material are arranged in a vertical series upon a central tube, the plates of each pair being placed with their concave surfaces facing one another, and the whole series being kept pressed together by a spiral spring at the top of the tube. The pile of plates is placed in a vessel, and the water to be strained, is forced into the latter, and passes between the edges of the plates, through the central tube into a chamber, from which it is drawn off. The plates are cleansed from deposit by reversing the direction of flow of the water.—W. H. C.

Drying pulverised, granular, and like material in vacuo; Apparatus for ——. E. Passburg, Berlin. Eng. Pat. 3432, Feb. 12, 1906.

THE material to be dried is fed into the vacuum chamber, *a*, from the hopper, *g*, by the rollers, *w*, and w^1, which are provided with cavities, *v*, and v_1, and are rotated, air-tight, in the casing, *h*, by suitable external mechanism. A vacuum is maintained in the space, o^1, by an auxiliary air-pump, connected to the pipe, *l*, the inner end of which is protected by a wire gauze screen, *m*. The material passes into the drying-chamber, *a*, by the passage, o^2, and is distributed by the arms, *p*, on to the travelling bands, *c*, which pass round the rollers, *d*, and d^1, and over the heating plates, *b*. The rollers, d^1, pass through the casing, *a*, being rotated by external gearing, and the material passes from band to band, and is finally expelled from the bottom of the casing by an apparatus similar to that by which it was introduced. The material is subjected to progressively decreasing temperatures by varying the distance between the bands, *c*, and the heaters, *b*, which touch the upper bands but are at some little distance from the lower ones. The same result may be attained by keeping the bands in contact with the plates, and heating the upper plates by steam and the lower ones by hot water.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 748.)

Moss; White —— for fuel in Sweden. T. Palmberg, Teknisk Tidskrift, Stockholm, 1905, General section, 283—284. Proc. Inst. Civil Eng., 1905—1906, **163**, 63—64.

IN the Midlands of Sweden there are large tracts of white moss ("sphagnum"). By passing the wet material between rollers, its water content can be reduced to 50 per cent., and experiments have shown that a mixture containing as much as 70 per cent. of the coarse powder thus obtained, together with 30 per cent. of air-dried peat, can be burnt in a Talin's so-called "combined gas-generator and half gas-fired furnace," without impairing the working of the latter, or reducing the steam-pressure of 6 kilos. per sq. cm. (85 lb. per sq. in.). Trials in a tube-welding furnace showed that 616 kilos. of air-dried white moss, cut into pieces, and containing a little over 38 per cent. of water, gave out as much heat as 356 kilos. of steam-coal. The calorific value of white moss is 4300—4700 heat units, so that the pressed powder containing 50 per cent. of water would be equal to 31—33 per cent. of its weight of good steam-coal, or probably more, if used in a furnace suitable for burning the water-gas formed by its combustion.—A. S.

Gas-engine exhaust gases; Resistance of metals to corrosion by ——. J. Pintsch. Gasmotorentechnik, 1906, **6**, 51—54. Science Abstracts, 1906, **9B**, 293.

SHEETS of various metals were exposed in the exhaust vessel (at 370° C.) of a gas-engine supplied with producer gas of low calorific value (800—900 kilo.-cals. per cb. m.), and the loss or gain in weight was noted after five months in one set of tests, and after 5½ months in another. Bronzes containing tin were attacked most by the gases; copper also was considerably corroded. The metals least acted upon were nickel and brass, the latter being more resistant the higher its content of zinc. Nickel steel was not corroded so much as cast iron, and was better the higher its content of nickel. The outer crust on cast iron exerted a strong protective influence, but even machined cast iron was not strongly attacked.—A. S.

Gases; Optical analysis of industrial ——. F. Haber. Z. Elektrochem., 1906, **12**, 519—520.

THE refractive power of a gas, or mixture of gases, can be determined with great accuracy, by observing the displacement of image which occurs on looking with a telescope at a distant object through a glass prism into which the gas is led. In applying this method to the analysis of gases, the author uses an apparatus (made by Zeiss of Jena) consisting of a prism telescope, a glass prism for the gas or air, and a mirror. The observer looks, not at a distant object, but at a luminous spot situated in the telescope itself. On looking into the instrument, one sees a dark shadow, which falls upon a scale in a position corresponding to the composition of the gas in the prism. The method is simple, and has the advantage that the refractive index of a sample of gas (as compared with air) remains the same, provided any changes of temperature and pressure, affect equally the

sample, and the air under comparison. If chimney gases be led through the prism, an increase of 0·9 per cent. in the carbon dioxide causes the shadow to be displaced one division on the scale. The instrument can be adapted for photographic registration, instead of for direct reading, or the image of the shadow can be made visible at a distance. The apparatus is sensitive to 0·0000003 in the refractive index, corresponding to a change of 0·2—0·25 per cent. of carbon dioxide in chimney gases. Methane, hydrogen, hydrochloric acid, and hydrocyanic acid, can be determined in air with the same delicacy. In the case of acetylene or sulphuretted hydrogen, the exactitude is twice as great; for sulphur dioxide, 2½ times as great; and for pentane and benzene vapour, nearly ten times as great.—H. B.

Incandescent black bodies; Brightness of ——, and a simple pyrometer. W. Nernst. Physik. Zeits., 1906, **7**, 380—383. Chem. Centr., 1906, **2**, 294.

Previous determinations of the quantity of light (in Hefner candles) emitted by 1 sq. mm. surface of a black body at different temperatures, have yielded the following results, the temperatures being given in absolute degrees:—At 1449°, 0·0042 candle; at 1597°, 0·012; and at 1707°, 0·064 candle. In the author's experiments, a Wanner pyrometer, graduated optically (Ber. deutsch. phys. Ges., **4**, 146), was used for measuring the temperatures, and the light emitted by a cylinder blackened with manganese dioxide, when heated in an electric furnace, was measured. As a standard, the melting point of gold was taken as 1064°C. + 273° = 1337° absolute, whilst the radiation constant was taken as 14,600. The radiation of the black body was ascertained by comparison with incandescent electrodes photo-standardised for different current-strengths. The values given above were confirmed, and the following additional values were determined:—0·06 Hefner candle at 2027° absolute, 1·80 at 2182°, and 2·72 Hefner candles at 2290° absolute. The values obtained, agree well with Planck's equation: $\log_{10}$ Hefner candles $= -\frac{A}{T} + B$, where T is the absolute temperature, and A and B are constants (A = 11,230, B = 5·367), and temperatures may be ascertained in this way by determining the quantity of light emitted by a black body (carbon, osmium, tantalum, or a Nernst electrode). A photo-standardised incandescent electrode is thus by itself a fairly accurate pyrometer. For higher temperatures 1-ampère electrodes from Nernst lamps are especially suitable; after being used for some time at normal E.M.F., they give concordant results with a lower E.M.F. At the melting point of platinum, 1 sq. mm. surface of a black body emits 0·634 Hefner candle, and at the melting point of iridium (2348°), 12·1 candles. In practice the Hefner candles would be replaced as standards by standardised electric lamps. One sq. mm. surface of a black body at 1819° yields one candle, and gives light which is not so red as that of the Hefner candle.—A. S.

Nernst lamp; Temperature of the ——. L. W. Hartmann. Physical Rev., 1906, **22**, 351. Electrician, 1906, **57**, 579—580.

As other authors have indicated, measurements of the temperature of the Nernst glower based on its radiating power or photometric qualities, give values which are much too high. This is due to the fact that the glower emits selective radiation, and consequently departs from the simple laws which hold for the "black body."

The author has applied the method of using a series of thermo-junctions with wires of gradually decreasing thickness and extrapolating, to find the value of the temperature corresponding to a couple of zero cross-section, thus eliminating the conduction of the wires. The values obtained with six different glowers, some with direct, others with alternating current, and with the junctions placed very differently in the single cases, vary from 1505° C. to 1535° C. In comparison with this the author's measurements by radiation methods indicate a temperature of about 2090° C.

These values are of importance in considering the relative efficiency of the Nernst glower. If the high temperature, as indicated by the radiation measurements, be correct, the watts lost per centimetre, are very low (1 to 5 watts), or 5 to 7 per cent., compared with a "black body" of the same temperature; but, considering the temperature indicated by the thermo-element, 42 watts are lost per centimetre, which is a percentage of 70·5.

—R. S. H.

English Patents.

Gas producers; Impts. in suction ——. E. W. Anderson, Solihull, Warwick, and Kynoch, Ltd., Witton, Staffs. Eng. Pat. 14,098, July 8, 1905.

The producer is provided with a perforated water-supply pipe, which may be swung beneath the fire-grate as soon as the fire is lit, on starting the producer. Water is thus squirted up into the fire, supplying the latter with steam, and generating good gas, until the vaporiser is hot enough to generate steam in the normal working manner, whereupon the perforated pipe is withdrawn.—H. B.

Coal gas and producer gas; Manufacture of ——. J. Parry and H. J. Pillinger, Newport, Mon. Eng. Pat. 15,226, July 25, 1905.

One or more inclined or vertical retorts are arranged within a producer having the form of a blast furnace. The retorts are charged with a mixture of coal and lime, and after the illuminating gas has been driven off completely from the coal, the residual mixture is discharged and fed into the top of the producer. The heat generated in the latter is controlled by regulating the blast of air (hot or cold) admitted by the tuyères, and ordinary producer gas is led off from the upper portion of the furnace. Owing to the addition of lime to the fuel, the ash becomes fused and is drawn off in the molten condition through a tap hole at the base of the furnace.—H. B.

Gas and dense coke from coal dust; Manufacture of lighting ——. A. Pistorius, Schloss Waldenburg, Germany. Eng. Pat. 3870, Feb. 16, 1906.

Dry coal dust is mixed intimately with finely ground lime (say, 3—4 per cent.) and finely ground pitch (say, 5—6 per cent.), the mixture is compressed into briquettes under high pressure, and the briquettes are carbonised in gas retorts in the usual manner.—H. B.

Power-gas producers; Impts. in ——. F. Müller, Darmstadt, Germany. Eng. Pat. 4077, Feb. 19, 1906.

In order to allow of the use of fine, granular, and brittle fuel in a tall producer, and to avoid the blocking or choking effect due to the weight of the charge, one or more rows of hollow bridges with an inverted V-shaped top, and open bottom, are built across the producer. These help to support the fuel, and also serve for the introduction of air and for the extraction of gas, for which purpose some of them may be perforated.—W. H. C.

Filaments [Vanadium carbide] for electric incandescent lamps; Impts. in ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co. of Schenectady, N.Y., U.S.A. Eng. Pat. 19,264, Sept. 23, 1905.

Vanadium oxide, 100 parts, is mixed intimately with Acheson graphite, 47 parts, and with enough coal-tar to make a stiff dough. The dough, formed into balls, is baked in a gas furnace and then heated in an electric arc furnace until reduction, with formation of vanadium carbide, is complete. The carbide is formed into lamp filaments by mixing it with a small quantity of ceresin, extruding the mixture into threads, and firing the latter, packed in graphite, in a vacuum furnace at a high temperature. Filaments of carbide may also be obtained by heating wires of metallic vanadium to a high temperature in contact with powdered carbon or a gaseous hydrocarbon.—H. B.

United States Patents.

Combustion; Process of regulating ——. P. Larsen, Copenhagen, Denmark. U.S. Pat. 824,728, July 3, 1906.

The combustion is regulated by changing the relative positions of the openings through which the air and fuel are separately introduced into the furnace, and also by moving the point of their introduction further into or out of the furnace.—W. H. C.

Furnaces; Process of combusting coal mixtures in ——. G. Mielenhausen, New York, N.Y. U.S. Pat. 825,066, July 3, 1906.

The coal on the grate is surrounded on three sides by a semi-tubular mantle of steam under pressure, introduced through a jet. The pressure is highest in the centre above the fuel, and lowest at the sides near the bars. The light, completely burnt products of combustion escape to the flues through the steam mantle at its highest point, whilst the particles of coal-dust and the heavy partially-burnt gases are kept in contact with the heated bed of fuel by the sides of the mantle until they are completely burnt.—W. H. C.

Gas-producer. J. Reuleaux, Wilkinsburg, Pa. U.S. Pat. 824,883, July 3, 1906.

The producer is a vertical chamber built of refractory material, and is provided with two systems of air-inlet openings. One is a vertical pipe which passes up through the water-seal ash-pit into the lower part of the producer, and the other consists of a number of air-inlets which project into the producer from an annular air-chamber built into the brickwork of the producer just above the lower conical part and at the same level as the central inlet. Both systems of air-inlets are connected by pipes provided with cylindrical dampers.—W. H. C.

Gas-analysis apparatus. J. M. Morehead. U.S. Pat. 824,999. July 3, 1906. XXIII., page 828.

Calcium carbide; Producing ——. J. M. Morehead. U.S. Pat. 825,234, July 3, 1906. XI*A*., page 817.

French Patents.

Gas-producer; "Hydroxydric" ——. E. Bardot. Fr. Pat. 362,994, Feb. 5, 1906.

The producer, which is intended more particularly for use with gas engines of 8 h.p. or less, is fed with oxygen instead of air, so that the mixed water-gas generated may contain but little nitrogen. The oxygen may be obtained from an ordinary cylinder of that gas, a floating bell-holder being interposed between the cylinder and the engine, or it may be generated by causing the hot gases from the producer to flow, on their way to the engine, round vessels containing barium peroxide, the oxygen liberated being drawn into the producer. Instead of barium peroxide, a mixture of manganese dioxide and caustic soda may be employed, and in this case part of the steam generated in the vaporiser of the producer is led into the mixture.—H. B.

Carburetter for the production of [*air*] *gas for lighting or heating.* Soc. Le Radiogaz. Fr. Pat. 363,057, Feb. 7, 1906.

The apparatus consists of two gasholders and a carburetter. The bell of the first gasholder (which serves to draw in air and deliver it under pressure to the second gasholder) is caused to rise by a hydraulic piston, working in an upright cylinder attached to the bottom of the bell tank, and fed with water from the mains. As the bell rises, it draws in air through a pipe fitted with a non-return valve; it also raises a vertical rod, fitted with catches which bear upon a weighted, tipping-arm device. When the bell reaches a certain point, the tipping arm is thrown over, thereby shutting off the water supply to the hydraulic piston. The air in the holder, now under a pressure corresponding to the weight of the bell, is forced through a non-return valve into the second holder; and when the bell reaches a certain point in its descent, the tipping arm is thrown back, thereby reversing the valves, and again admitting water to the hydraulic piston. From the second holder the air passes through the carburetter, composed of a vertical casing having superposed horizontal trays, over which benzol or the like trickles. The apparatus works automatically in accordance with the consumption of the compressed air.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 748.)

Paraffin wax; Determination of the solidification point of ——. T. Fischer. Z. angew. Chem., 1906, **19**, 1323—1326.

With the object of obtaining concordant results the Verein für Mineralölindustrie at Halle devised the so-called Halle method, which has recently been modified as follows:—A beaker is filled to the brim with water, and a thermometer suspended so that its bulb is completely immersed. The water is heated about 5° C. or 6° C. above the melting point of the paraffin, and a piece of the wax about 7 mm. in size is taken from the middle of the sample, and placed on the surface of the water, care being taken not to touch it with the fingers. The water is allowed to cool slowly, and a note taken of the temperature at which an opaque film forms over the surface of the drop of paraffin. The author finds that if a fragment of paraffin solidifying at about 58° C. be placed on water at about 63°—64° C., a film begins to appear at the edges of the oily layer at about 59° C., and at about 58° C. the filming is complete, *i.e.*, when the determination is made as in the original method in a space protected by glass plates on all sides. In the later modification, however, there is frequently a complete filming over of the paraffin between 59° C. and 61° C., the film disappearing again in a few minutes. This is due to the influence of the colder air of the surrounding room, and with the other observations made, affords some explanation of the variation in the results (not infrequently 1·5° C. to 2° C.) recorded by different observers for the same sample. Hence the author has devised the following combined method with which such great differences are not possible:—About 120 grms. of the paraffin wax are melted and poured into a flask of about 125 c.c. capacity, which is thus filled nearly to the neck. The flask is then closed with a cork through which passes a thermometer graduated in $\frac{1}{5}$° C., and is placed in a wooden box closed with a lid in which is an opening for the thermometer. Periodical readings of the time and of the thermometer are now taken, and it will be found that the times between equal intervals of temperature increase shortly before the solidification point, until finally the thermometer records the same temperature for at least 10 minutes, this being taken as the solidification point of the paraffin wax. Considerable differences in the temperature of the room do not materially affect the results, and readings agreeing within $\frac{1}{10}$° C. can be obtained in duplicate determinations. In experiments with different samples of paraffin the author obtained by this method results from 1·1° C. to 2·4° C. lower than by the original Halle method, the differences increasing with the rise in the melting points of the paraffins. In the case of a mixture of paraffin waxes of widely divergent solidification points (*e.g.*, 60° C., 53° C., and 44° C. respectively) the thermometer does not keep constant for 10 minutes, but the author points out that such a mixture is useless for most practical purposes, and can hardly be regarded as a commercial product of paraffin wax factories.—C. A. M.

English Patents.

Gases obtained from the dry distillation or gasification of fuels; Treatment of ——. H. Koppers, Essen-Ruhr, Germany. Eng. Pat. 16,386, Aug. 11, 1905.

The crude gas is cooled to about 40°—45° C., whereby much of the water and about half of the ammonia are

condensed; it is next passed through a tar separator; then heated, by using it as a cooling medium in the coolers through which the hot crude gas flows; and finally scrubbed with sulphuric acid to remove the remainder of the ammonia. Owing to the heating of the gas prior to its entering the scrubber, no dilution of the liquor, due to condensation of water, occurs. The ammoniacal liquor obtained on cooling the crude gas is treated with lime in a distilling column, and the hot ammonia vapour is led into the same acid scrubber. The acid in the scrubber is kept at about 80° C., to minimise the condensation and dilution. The waste liquors from the distillation apparatus are discharged into the atmosphere by spraying them into hot chimney gases.—H. B.

Sulphate of ammonia; Apparatus for making ——. S. H. B. Langlands and H. O'Connor. Eng. Pat. 17,267, Aug. 26, 1905. VII., page 811.

UNITED STATES PATENTS.

Wood; Apparatus for distilling ——. E. G. Jewett, Bellingham, Wash. U.S. Pat. 824,872, July 3, 1906.

THE distillation is carried on in vertical cylindrical retorts set in brickwork with a furnace between each pair of retorts. The wood is lowered into the retorts in crates, formed of radial bars connected by annular bars, and having conical bottoms. Water-spraying pipes are attached to the crates.—W. H. C.

Wood-alcohol; Process of making ——. H. O. Chute. U.S. Pat. 824,906, July 3, 1906. XVII., page 824.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page 752.*)

Aromatic nitro compounds; Introduction of amino groups into the nucleus of ——. J. Meisenheimer and E. Patzig. Ber., 1906, **39**, 2533—2542.

THE compound obtained by the action of hydroxylamine on *m*-dinitrobenzene in alcoholic alkali hydroxide solution was found to consist of 2.4-dinitroaniline and *m*-dinitro-*m*-phenylenediamine. The latter is obtained in almost theoretical quantity by dissolving the sodium salt resulting from the above reaction in a small amount of water, and strongly cooling the solution. It crystallises from alcohol in orange-yellow needles melting at 253°—254° C. Under similar conditions 1.3.5-trinitrobenzene yields a sodium salt, which when acidified forms picramide in fairly large quantity together with some trinitrophenylenediamine. From these results it is inferred that *m*-dinitro compounds are not reduced by means of hydroxylamine, but form substitution products.—D. B.

Nitro compounds; Reduction of ——, *by tin halides.* H. Goldschmidt and E. Sunde. Z. physik. Chem., 1906, **56**, 1—42.

IT has been previously shown (Z. physik. Chem., 1904, **48**, 435) that in the reduction of nitro compounds by stannous chloride and hydrochloric acid or by stannous bromide and hydrobromic acid, if the concentration of the acid be kept constant, the reaction is one of the second order. If the concentration of the acid be varied, the reaction velocity alters also, and approximately in proportion to the change in the concentration of the acid. Stannous bromide and hydrobromic acid effect the reduction of a nitro compound about eight times as rapidly as stannous chloride and hydrochloric acid of the same concentration. The results previously obtained indicated that the reduction is effected not by stannous ions, as has been generally accepted, but either by complex compounds, $SnCl_3H$ or $SnBr_3H$, or by the ions, $SnCl_3'$ or $SnBr_3'$. Further experiments with *m*- and *o*-nitrophenol and *m*-nitrobenzaldehyde have confirmed these results. In the case of *o*- and *p*-nitrobenzenesulphonic acids and *o*-nitrobenzaldehyde, also, the reaction velocity increases with the concentration of the acid, but to a greater extent than is required by theory. *o*-Nitrobenzaldehy reacts not with three molecules of stannous chloride, other nitro compounds do, but only with two, anthra being formed:—

$$C_6H_4(NO_2)CHO + 4H = C_6H_4<\begin{matrix}N\\CH\end{matrix}>O + 2H_2O.$$

In experiments with *m*-nitrobenzenesulphonic acid a *o*-nitrobenzaldehyde, it was found that a portion of t hydrochloric acid could be replaced by sodium chloride barium chloride, without any noticeable effect on t reaction velocity. This fact may be found useful practice in cases where a large excess of acid is injurio The behaviour of metal chlorides as substitutes for hydr chloric acid proves that it is not the complex compour $SnCl_3H$, but the ion, $SnCl_3'$, which is the actual reduci agent. It is pointed out that the results in gene obtained by the authors confirm the correctness of Habe view that the reduction of nitro compounds in ac solution proceeds according to the scheme:—

$$R.NO_2 \rightarrow R.NO \rightarrow R.NHOH \rightarrow R.NH_2.$$

—A. S.

Azoxy compounds. A. Angeli and G. Marchetti. Atti Accad. dei Lincei Roma, 1906, **15**, [5], 480—48 Chem. Centr., 1906, **2**, 325—326.

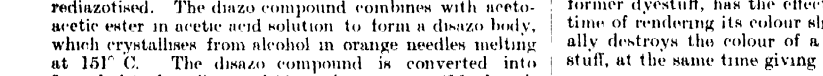
ANILINE and nitrobenzene on treatment with metall sodium yield a compound, of the probable formul $C_6H_5N(OONa)N(Na)C_6H_5$, which ignites spontaneous in the air, and is readily hydrolysed by water, a notat quantity of azoxybenzene being among the decompositic products. *α*-Naphthylamine and *α*-nitronaphthale yield *α*-azoxynaphthalene in an analogous manne Aniline and *α*-nitronaphthalene on the one hand, a nitrobenzene and *α*-naphthylamine on the other, yie two isomeric compounds, probably: $C_6H_5N:N(:O)C_{10}$ and $C_6H_5N(:O):NC_{10}H_7$. The condensation of amin with nitro-derivatives in presence of sodium thus appea to be a general reaction. The following cases have be examined by the authors:—

$$(OH)NH_2 + NO_2C_6H_5 = OH(N_2O)C_6H_5 + H_2O;$$
$$(OH)NH_2 + NO_2OC_2H_5 = OH(N_2O)OH + C_2H_6O;$$
$$C_6H_5NH_2 + NO_2OC_2H_5 = C_6H_5(N_2O)OH + C_2H_6O;$$
$$C_6H_5NH_2 + NO_2C_6H_5 = C_6H_5(N_2O)C_6H_5 + H_2O.$$

—A. S.

Azo dyestuffs; Decomposition of —— *by sodium hydr sulphite.* E. Grandmougin. Ber., 1906, **39**, 2494—249

THE decomposition of azo dyestuffs by sodium hydr sulphite (hyposulphite) affords a ready means of dete mining their constitution, and is, in many cases, superi to the well-known method with stannous chlorid The aqueous or alcoholic solution of the dyestu is heated to boiling, and decolorised by means a concentrated solution of sodium hydrosulphit the reaction-products being subsequently isolated in an suitable manner. A boiling aqueous solution of Orange I decolorised with sodium hydrosulphite, and then filtered yielded, on cooling, glistening colourless needles of fre aminonaphthol, the yield being the same as by the stannou chloride process (Ber., 1892, **25**, 981). Benzeneazo-*β* naphthol when treated in alcoholic solution with sodiur hydrosulphite yielded aniline and amino-*β*-naphtho From 2-benzeneazo-*α*-naphthol, treated in a simila manner, 2-amino-1-naphthol was obtained. The latte was converted quantitatively into a diacetyl derivativ (m.pt. 116° C.) by boiling for from 1 to 2 hours with a equal weight of fused sodium acetate and six times it weight of acetic anhydride. By partial saponificatio of the diacetyl compound, the N-acetyl derivative $C_6H_3(OH).NH.COCH_3$, is produced, m.pt. 128°—129° C This substance combines with diazonium compounds, bu the resulting dyestuffs are of no technical value. *α*-Nitroso *β*-naphthol yields amino-*β*-naphtholsulphonic acid o reduction with sodium hydrosulphite, whilst azobenzen is converted almost quantitatively into hydrazobenzene



—A. S.

Disazo compounds of p-phenylenediamine; Fatty-aromatic mixed —— with heterocyclic side chains. C. Bülow and F. Busse. Ber., 1906, **39**, 2459—2466.

DIAZOTISED *p*-amino-acetanilide may be readily combined with benzoylacetone in acetic acid solution to form acetyl-*p*-aminobenzene-azo-benzoylacetone

$$CH_3CO.NH.C_6H_4.N:N.CH(CO.CH_3).CO.C_6H_5,$$

m.pt. 171° C., which crystallises from alcohol in golden yellow needles, and is sparingly soluble in water. On treating this substance with hydroxylamine a practically quantitative yield of the corresponding isoxazole [acetyl-*p*-aminobenzeneazo-4]-3-methyl-5-phenylisoxazole is obtained. This product, m.pt. 228° C., crystallises from alcohol in yellow needles, practically insoluble in water. It may be hydrolysed with dilute caustic soda, and then rediazotised. The diazo compound combines with aceto-acetic ester in acetic acid solution to form a disazo body, which crystallises from alcohol in orange needles melting at 151° C. The disazo compound is converted into 3-methyl-5-phenylisoxazole[1-azo-benzene-azo-4]-1-phenyl-3-methyl-5-pyrazalone,

if treated with phenylhydrazine in glacial acetic acid solution. The new substance is insoluble in water, but may be obtained from nitrobenzene in light red needles m.pt. 205°—206° C. The same product is obtained by reversing the above procedure and combining [*p*-amino-benzene-azo-4]-1-phenyl-3-methyl-5-pyrazolone with benzoylacetone, and subsequently treating the product of the reaction with hydroxylamine.—H. L.

Trinitromethane and triphenylmethane. A. Hantzsch Ber., 1906, **39**, 2478—2486.

THE author attempted to prepare hexanitroethane by treating the silver salt of nitroform $(NO_2)_3CAg$ with iodine in ethereal solution, but obtained instead iodotrinitromethane $(NO_2)_3CI$, m.pt. 58° C. This substance is formed immediately even at a temperature of —75° C. It reacts readily with silver nitrite to form tetranitromethane, but is quite indifferent to the very reactive silver salt of nitroform. The author points out that hexa-nitroethane is thus evidently a substance of abnormal reactivity or instability, and is probably not capable of existence. He argues from analogy that Gomberg's very reactive "triphenylmethyl," which is dimolecular, is probably hexaphenylethane. The analogy between trinitro- and triphenylmethane derivatives is supported by the stability of both tetranitro- and tetraphenylmethane. —H. L.

Dyestuff-ammonium bases; A physiological contribution to the question of the constitution of ——. H. Führer. Ber., 1906, **39**, 2437—2438.

METHYLATED-ammonium compounds in general show a characteristic physiological curara reaction. This reaction is obtained with Methyl Green, but not with Auramine, Malachite Green, Crystal Violet, and Methylene Blue. According to the views of Hantzsch, Auramine, Malachite Green, and Crystal Violet in the free state are pseudo-bases, whilst Methyl Green and Methylene Blue are true ammonium bases. The two latter substances should therefore behave physiologically as other methylated ammonium compounds. Methylene Blue is thus anomalous in this respect, and the fact is regarded by the author as a support for Kehrmann's *o*-quinonoid azthionium formula for this dyestuff. (See this J., 1906, 173.)—H. L.

Methylene Green. E. Grandmougin and E. Walder. Z. Farben.-Ind., 1906, **5**, 285—286.

BY a method of quantitative reduction, Gnehm and Walder (this J., 1906, 368) have recently proved that Methylene Green, which is prepared by the action of nitrous acid on Methylene Blue (this J., 1887, 508) is a nitro compound. The dyestuff in question may be obtained, as Noelting has shown, by the action of nitric acid on a sulphuric acid solution of Methylene Blue. The authors find that it may also be produced by the action of nitric acid on a solution of the same dyestuff in acetic acid. To this end, a solution of Methylene Blue (32 grms.), free from zinc, in acetic acid (150 grms. of a 40 per cent. solution), to which nitric acid (14·3 grms. at 36° B.) is added, is heated to from 80° to 82° C., at which temperature the reaction takes place. When this is completed, water (200 c.c. of hot, followed by 300 c.c. of cold) is added, and then common salt (50 grms.) and zinc chloride (25 grms. of a solution at 40° B.). The zinc chloride double salt thus obtained, is purified by reprecipitation from a solution containing hydrochloric acid.

The presence of Methylene Blue in admixture with Methylene Green, which is difficult to observe with the spectroscope, may be detected by means of ammonia. This reagent, when added to an aqueous solution of the former dyestuff, has the effect, after the lapse of a little time of rendering its colour slightly paler, while it gradually destroys the colour of a solution of the green dyestuff, at the same time giving a brown precipitate.—E. B.

Hydroxylamine, Decomposition of ——, in presence of hydroferrocyanic acid. Formation of crystallised ferricyanogen-violet and nitroprusside. K. A. Hofmann and H. Arnoldi. Ber., 1906, **39**, 2204—2208.

ON boiling an aqueous solution containing equal weights of potassium ferrocyanide and hydroxylamine hydrochloride, ammonium chloride and a nitroprusside are formed, nitrogen and hydrocyanic acid are evolved, and a deep blue crystalline powder with a purple lustre is precipitated. A filtered solution of 30 grms. of hydroxylamine hydrochloride was mixed with a solution of 30 grms. of potassium ferrocyanide, and the whole heated on the water-bath till neither ferri- nor ferrocyanide could be detected in a portion of the filtered solution. The solution was then decanted off, and the residual blue powder washed with a hot 15 per cent. solution of hydroxylamine hydrochloride, and afterwards with water. The blue compound forms microscopic cubes with a brilliant purple lustre. When treated with a strong solution of alkali in the absence of air, it yields ferric hydroxide and potassium ferrocyanide. It is not acted upon by boiling potassium nitrite solution, nor by ferric chloride solution. It is not dissolved by water, dilute mineral acids, oxalic acid, acetic acid, or a solution of Rochelle salt; it is attacked slowly by 4 per cent. ammonia solution at the ordinary temperature, with formation of ferric hydroxide, but is not acted upon by hydrogen sulphide. It thus corresponds with respect to properties and colour with Williamson's violet (this J., 1905, 1221), and it must therefore be regarded as a ferric-ammonium ferrocyanide of the following constitution:—

$$NH_4(FeCy_6)\ Fe'''_2(FeCy_6)NH_4.$$

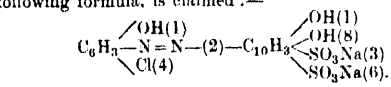
The compound is quite anhydrous, and this affords another objection against the view that the intense colour of the blue iron-cyanogen compounds is due to the presence of combined water. The true cause of the colour is the simultaneous presence of ferric and ferrous iron in the molecule (see this J., 1905, 1221). The new violet compound can be obtained perfectly pure in a crystallised condition, whereas Williamson's violet is amorphous, and usually impure. The same violet compound is obtained if ferricyanide be used instead of ferrocyanide, indicating that the ferrocyanide is in the first place oxidised by the hydroxylamine. In the reaction, one-half of the ferrocyanide is converted into the violet compound, and the other half into nitroprusside; the quantity of hydrocyanic acid evolved is equivalent to one-fourth of the ferrocyanide used. (See also this J., 1904, 1209.)—A. S.

ENGLISH PATENT.

Dyestuff; Manufacture of a black —— [from coal or lignite], with by-products, including a tanning agent or a second black dyestuff. D. Lerman, B. B. D. Schwartz, and P. Pikos, Pozega, Hungary. Eng. Pat. 3107, Feb. 8, 1906.

COAL or lignite is pulverised, and heated to 90°—110° C. in an open vessel or under pressure, with 0·5 to 15 per cent.

of an aqueous solution of an alkali hydroxide or carbonate or other "solvent," varying according to the nature of the material used; heating is continued till the bituminous constituents are dissolved and the residue carbonised. The latter is separated, washed, and distilled, the distillate consisting of gases, which may be used for illuminating purposes, and also of tar and other oils; the residue, when pulverised, is said to be a valuable black dyestuff. The aqueous solution of bituminous substances is precipitated by addition of acid, the precipitate being of value as a tanning material, it is stated; the precipitate may, however, be converted into a black dyestuff similar to that first obtained by distillation, as above.—T. F. B.



UNITED STATES PATENTS.

Dyestuff; Ortho-oxyazo ——. K. Schirmacher and F. Schmidt, Assignors to Farkwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pat. 826,279, July 17, 1906.

SEE Ger. Pat. 167,333 of 1905; this J., 1906, 471.—T.F.B.

Dyestuff; Ortho-oxymonoazo ——. K. Schirmacher and F. Schmidt, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pat. 826,280, July 17, 1906.

THE *o*-hydroxyazo dyestuff, having as a sodium salt the following formula, is claimed:—

Its aqueous solution is bluish-red, becoming bluish-violet on addition of sodium carbonate. It dyes wool red from acid baths, and chromed wool blue. (See also Ger. Pat. 167,333 of 1905; this J., 1906, 471.)—T. F. B.

Dyestuff; Ortho-oxymonoazo ——. F. Schmidt and K. Schirmacher, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pats. 826,281 and 826,282, July 17, 1906.

THE dyestuff claimed is analogous with that described in U.S. Pat. 826,280 (see preceding abstract), the chlorine in the latter being replaced by the methyl group. It dyes wool blue-red from acid baths, the dyeings of the chrome lake being blue.—T. F. B.

Alizarinsulphonic acid and process of making same. M. Iljinskij, Crefeld, Assignor to R. Wedekind und Co., Uerdingen, Germany. U.S. Pat. 826,509, July 17, 1906.

A NEW alizarinmonosulphonic acid is obtained by the action of fuming sulphuric acid on alizarin in presence of mercury. Its potassium salt, which is carmine-coloured, gives a deep red solution in potassium chloride solution, which gelatinises on cooling. Its aqueous solution gives a purple coloration on addition of copper sulphate.—T. F. B.

Anthraflavindisulphonic acid and process of making same. M. Iljinskij, Crefeld, Assignor to R. Wedekind and Co., Uerdingen, Germany. U.S. Pat. 826,510, July 17, 1906.

ANTHRAFLAVIN, when treated with fuming sulphuric acid in presence of mercury, is converted into a new disulphonic acid, which forms yellow microscopical rectangular prisms, not pointed; it is soluble in hot water, giving a red solution, which is converted to deep red-brown on addition of copper sulphate.—T. F. B.

FRENCH PATENT.

Organic or inorganic compounds; Process for the reduction of ——. S. Kapff. Fr. Pat. 362,985, Feb. 3, 1906. VII., page 811.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 756.)

ENGLISH PATENTS.

Waterproofing composition, applicable also as a vehicle for pigments. T. L. Leishman. Eng. Pat. 4533, Feb. 24, 1906. XIII*B*., page 821.

Dyed or naturally coloured material; Removal of colouring matter from ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 12,517, May 29, 1906.

THE alkali salts of formaldehyde-sulphoxylic acid, either alone, or in conjunction with formaldehyde-bisulphites, possess only feeble reducing properties in neutral solution, even when boiling; in acid solutions, however, the reducing properties are much increased, but decomposition also occurs, with precipitation of sulphur in the fibre. This objection is not apparent, if the sparingly soluble basic zinc salt of formaldehyde-sulphoxylic acid (described in the second Addition to Fr. Pat. 350,607 of 1905; this J., 1905, 1299 and 1300) is used in acid solution, no decomposition taking place; acetic acid, sulphuric acid, and especially formic acid, may be used. The discharging bath may contain, for example, three parts of the basic zinc salt, and three to five parts of formic acid to every 100 parts of the material to be treated; the materials are heated slowly to boiling, and boiled for about 10 minutes, or until a portion of the bath does not reduce Indigo Carmine solution.—T. F. B.

Oiling of cotton and other vegetable fibres; Process for the ——. J. C. Fell, London. From E. Korndörfer, Asch, Bohemia. Eng. Pat. 13,580, July 1, 1905.

THE persistent emulsions obtained from vegetable or animal fat with mineral oils and ammonia, do not appreciably improve the appearance of cotton yarn, especially that dyed with sulphide blacks; excellent results are stated to be obtained, however, by the addition of alkaline-earth salts, preferably chlorides, to the emulsions. 100 kilos. of cotton yarn dyed with a sulphide black are passed for half an hour through a hot bath containing 1000 grms. of 80 per cent. Turkey red oil, 800 grms. of olive oil or cocoa-nut fat, 800 grms. of "best refined" paraffin oil, 200 grms. of ammonia (sp. gr., 0·91) and 700 grms. of crystallised magnesium chloride; the liquid is removed from the material without rinsing; in the case of other black dyestuffs, the emulsion of oil as above is added to the dyebath.—T. F. B.

Drying yarn or other textile materials in hanks; Machines for ——. A. N. Marr, Thorner, Yorks. Eng. Pat. 15,133, July 24, 1905.

THE machine consists of a drying chamber open at both ends, and provided with a perforated floor and ceiling, which communicate with air spaces above and below the drying chamber; circulating air spaces, arranged at either end of the drying chamber, are divided into two sections, one of which contains a suitable apparatus for heating the air, and both of which contain a fan or fans for circulating the air through the air spaces, and thence, through the perforations, to the hanks of yarn, which are carried on a travelling web within the drying chamber. It is stated that the drying is performed quite evenly by this machine.—T. F. B.

Printing indigo colouring matter; Process of ——. H. S. A. Holt and K. Reinking, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 826,428, July 17, 1906.

SEE Eng. Pat. 6495 of 1905; this J., 1905, 543.—T.F.B.

FRENCH PATENTS.

Cuprammonium solutions [for manufacture of artificial silk]; Purification of ——. A. Lecœur. Fr. Pat. 362,986, Feb. 3, 1906.

THE ammoniacal solution of cupric hydroxide is subjected to dialysis to deprive it of crystallisable salts, such as sodium chloride and potassium sulphate, the presence of which is stated to induce decomposition of the cuprammonium at ordinary temperatures; whereas, when thus purified, the solution is said to be stable, and in suitable condition to dissolve cellulose to a viscid solution, appropriate to the manufacture of artificial silk.—E. S.

Dyeing with sulphide dyestuffs; Process for ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 363,028, Feb. 6, 1906. Under Int. Conv., March 30, 1905.

THESE dyestuffs are dyed with the addition of various organic acids, which have reducing properties. The acids increase the affinity of the dyestuffs for the fibre, and also prevent any action of the sulphur compounds on animal fibres, so that the dyestuffs can be used for dyeing solid shades on half-silk, half-wool, or other mixed fabrics.

Example.—1·6 kilos. of Katigen Black T. G. extra are dissolved in a solution of 2·4 kilos. of crystallised sodium sulphide in water. This solution is made up to 200 litres with water, and 4 kilos. of salt, a solution of 600 grms. of calcined sodium carbonate, and 1·2 kilos. of commercial lactic acid are added. 10 kilos. of half-wool are placed in this solution, heated to 60° C., and dyed for one hour at this temperature. After dyeing, the material is rinsed with water, and then with dilute acetic acid. The wool can be dyed to shade by topping in a fresh bath with an acid dyestuff.—A. B. S.

Organic or inorganic compounds; Process for the reduction of ——. S. Kapff. Fr. Pat. 362,985, Feb. 3, 1906. VII., page 811.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 757.)

UNITED STATES PATENT.

Wall-coverings; Machine for printing decorative materials and ——. E. C. Baeck and R. R. Bertelli, New York, Assignors to Baeck Wall Paper Co., New York. U.S. Pat. 825,693, July 10, 1906.

A CONTINUOUS web or strip of the material is guided by rollers over and around an impression-cylinder, and means are provided for applying to the material a background of any desired character. The printing-roller is of relatively large size, and contains a complete continuous design suitable for so much of the wall of a room as is to be covered with single lengths of material. A device is provided for applying colouring material to the printing-roller, and a belt and graduated pulleys for driving the impression-cylinder and printing-roller in unison at the same surface speed.—B. N.

FRENCH PATENT.

Wood dyeing; Process of ——. M. Grünhut. Fr. Pat. 362,997, Feb. 5, 1906.

THE wood is first steamed in order to remove albuminous matters, and is then impregnated with chemical products in order to produce the colour desired. The colours are obtained by impregnating the wood with two or more chemicals in turn, the chemicals employed reacting on one another inside the wood, and so producing a very intimate dyeing effect—*e.g.*, to produce a reddish-brown, the wood is first impregnated with a solution of potassium thiocyanate (sulphocyanide) and then, six hours later, with a solution of ferric chloride.—A. B. S.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 760.)

Ozone and nitric oxide; Thermic formation of —— in moving gases. F. Fischer and H. Marx. Ber., 1906, **39**, 2557—2566.

THE formation of ozone at high temperatures in air or oxygen can be shown without sudden cooling (see this J., 1906, 314), if the stream of air be blown away from the high-temperature space with sufficient velocity. In this way the authors find that ozone, hydrogen peroxide, and nitric oxide are all formed in the hydrogen flame, and that with the Nernst filament the product varies with the speed of the current of air, nitric oxide being formed at a low, and ozone at a high speed. By regulating the speed, it may be possible to form nitrogen oxides and ozone in such proportions that the final product, after reacting with water, may be entirely nitric acid.—J. T. D.

Hydriodic acid; Rapid method for the preparation of ——. F. Boudroux. Bull. Soc. Chim., 1906, **35**, 493—494.

SULPHUR dioxide reacts with iodine dissolved in barium iodide solution, yielding hydriodic acid and insoluble barium sulphate. Working details for the preparation of the acid are given. 50 grms. of iodine are slowly added to 60 grms. of barium peroxide suspended in 100 c.c. of warm water. The clear liquid is separated, and further 50 grms. of iodine are dissolved in it. Then a current of sulphur dioxide is passed through the solution until colourless. After filtering, acid of about 35 per cent. strength, containing only traces of sulphuric acid, is obtained, and this may be concentrated by distillation. 140 grms. of the hydrate boiling at 127° C. were obtained by the author in three hours.—F. SODN.

Alkaline-earth halogenates; Solubility of ——. *I. Barium halogenates.* M. Trautz and A. Anschütz. Z. physik. Chem., 1906, **56**, 230—242.

THE results obtained are given in the following table, the figures referring to the percentage of anhydrous salt in the saturated solution, although in all three cases the solid phase consisted of a mono-hydrated salt.

Temperature. ° C.		Salt. Barium chlorate.	Barium bromate.	Barium iodate.

Substances soluble with difficulty; Studies of the solubility of ——. *II. Solubility of silver chloride, bromide, and thiocyanate at* 100° C. W. Böttger. Z. physik. Chem., 1906, **56**, 83—94.

THE solubilities were calculated from conductivity determinations made with the solutions contained in a bomb lined with platinum. The results, together with some

previously obtained at 20° C. by Kohlrausch, and by the author, are given in the following table:—

Salt.	Grm.-equivalents per litre.	
	at 100° C.	at 20° C.
Silver chloride	158×10^{-6}	$10{\cdot}6 \times 10^{-6}$
Silver thiocyanate	39×10^{-6}	$0{\cdot}88 \times 10^{-6}$
Silver bromide	20×10^{-6}	$0{\cdot}54 \times 10^{-6}$

The results show that the washing of precipitates of silver chloride with hot water in quantitative analysis is not free from risk. One litre of the solution saturated at 100° C. contains 0·0218 grm. of silver chloride, so that the loss on washing may be somewhat considerable, especially if, as frequently happens, unnecessarily large quantities of washing water are used.—A. S.

Sulphur; Ionisation of ——, and the complex ions of mercury. I. Knox. Z. Elektrochem, 1906, **12**, 477—481.

Both red and black mercuric sulphide are soluble in sodium sulphide solution, the amounts dissolved increasing from 0·008 to 0·783 for the red, and from 0·011 to 0·856 for the black modification, as the concentration of the sodium sulphide increases from 0·10 to 1·52 (all expressed in gram-molecules per litre). The solubility is due to the formation of a complex anion, which, from the rate of increase of solubility, as sodium hydroxide is added to the sulphide solution, and also from measurements of E.M.F., the author concludes to be HgS_2'', arising from the electrolytic dissociation of Na_2HgS_2.

At the end of the paper are calculated the concentrations of S″ and other characteristic ions in solutions used for the precipitation of sulphides (all containing a gram-molecule in the litre, save the solutions of hydrogen sulphide). The results are tabulated below:—

Solution.	S″	HS′	H_2S	H′	OH′
Na_2S	0·09	0·01	$1{\cdot}3 \times 10^{-7}$	$1{\cdot}3 \times 10^{-14}$	0·01
$NaHS$	$3{\cdot}6 \times 10^{-5}$	1·0	$3{\cdot}6 \times 10^{-4}$	$3{\cdot}3 \times 10^{-11}$	$3{\cdot}6 \times 10^{-4}$
$(NH_4)_2S$	$3{\cdot}0 \times 10^{-6}$	1·0 (about)	$5{\cdot}0 \times 10^{-3}$	$5{\cdot}0 \times 10^{-10}$	$2{\cdot}5 \times 10^{-3}$
NH_4HS	$1{\cdot}6 \times 10^{-7}$	0·93	0·07	$0{\cdot}7 \times 10^{-3}$	$1{\cdot}7 \times 10^{-6}$
Water saturated with H_2S	$1{\cdot}2 \times 10^{-15}$	$0{\cdot}95 \times 10^{-4}$	0·1	$0{\cdot}95 \times 10^{-4}$	$1{\cdot}8 \times 10^{-10}$
N/1$HC_2H_3O_2$, saturated with H_2S	$0{\cdot}6 \times 10^{-18}$	$2{\cdot}0 \times 10^{-6}$	0·1	$4{\cdot}0 \times 10^{-3}$	$3{\cdot}6 \times 10^{-12}$
N/1HCl, saturated with H_2S	$1{\cdot}1 \times 10^{-23}$	$0{\cdot}91 \times 10^{-3}$	0·1	1·0	$12{\cdot}0 \times 10^{-14}$

The low concentration of S″ ions in solutions of hydrogen sulphide is remarkable, in view of the completeness of the precipitation of metallic sulphides by these solutions.—J. T. D.

Sulphur; Vapour pressure of ——. W. Matthies, Physik. Zeits., 1906, **7**, 395—397. Chem. Centr., 1906, **2**, 204.

The author determined the vapour pressure of sulphur at temperatures below its boiling point. The temperatures were measured by a thermo-couple, graduated at the ordinary temperature, at 100° C., and at the boiling point of sulphur (444·53° C. at 760 mm. pressure). The values found by the author were as follows:—

Pressure.	Temperature.	Pressure.	Temperature.
mm.	°C.	mm.	°C.
1·35	210·2	20·5	265·0
3·20	222·4	53·5	306·5
5·54	234·4	133·0	352·5
8·45	241·8	250·1	379·4

Sicilian sulphur. Chem. and Drug., Aug. 4, 1906. [T.R

There has been much agitation among the produce of Sicilian sulphur on account of the combination know as the "Consorzio Obligatorio." The law institutin the "Consorzio" has now passed the Italian Parliamen and from August 1 the industry will be placed on new footing. The chief provisions of this Bill are follows:—

1. All the sulphur-producers are constituted into body for twelve years.

2. The crude sulphur will be sold exclusively for accoun and in the interests of its members.

3. Refining, grinding, and shipping of sulphur are fre

4. The exportation of crude sulphur for Europe open to all.

5. The Anglo-Sicilian Sulphur Co. may for the stock will hold on August 1, either join the Trust or sell it stock to it at 59 lire per ton of 1,000 kilos., f.o.b., payabl by debentures at par, bearing 3·65 per cent. per annu interest, free of present or future taxes, and redeemabl within twelve years by yearly drawings. The capita and interest are guaranteed by the Government, and is said the Anglo-Sicilian Co. has preferred to sell.

6. The Trust has the right to limit production, and wil be controlled by the following organisation:—

(*a*) A committee of fifty members, elected by th producers.

(*b*) A board of nine members, named in part by th Minister of Commerce, the Banco di Sicilia, and th Chambers of Commerce of the Sicilian province in which the mines are situated.

(*c*) A general manager named by the Government.

7. The law provides (*a*) for the institution of publi warehouses in the sulphur ports; (*b*) that the Banco d Sicilia may advance up to ten millions lire on thei warrants; (*c*) for creating a mining bank with fou million lire capital, with the object of assisting smal producers.

8. The law reduces railway freights, and exempts from taxes the production of sulphur and all the industries in which the national sulphur forms a principal element. This exemption, it is expected, will benefit the sulphur industry considerably.

Government intervention in the sulphur industry had become a necessity, as the American competition from the Louisiana sulphur mines had made itself felt even in the European markets. The Sicilian producers, however, may now lose their best market—the United States—as Mr. Frasch, the agent of the Louisiana mines, insisted, when negotiations took place at Rome, on reserving the whole of the American market for the home product. The magnitude of this loss may be gathered from the fact that the American consumption of sulphur last year amounted to over 600,000 tons, of which Sicily supplied 70,000 tons. As the American output grew, the imports from Sicily gradually declined. In 1902, 170,000 tons were taken from Sicily by the United States, so that there has been a loss of 100,000 tons in three years. Two years ago Italy and Sicily produced 96 per cent. of the world's output of sulphur, but the pendulum is now swinging the other way. One of the features of the new Italian law is the limiting of production if necessary. In May last the stocks in Sicily amounted to 424,640 tons, compared with 313,625 tons in 1905.

Barium carbonate. U.S. Customs Circular. Oil, Paint, and Drug Rep., Aug. 6, 1906. [T.R.]

The decision of the Board of United States General Appraisers (T.D. 25,504) of Nov. 16, 1901, holding that precipitated barium carbonate was dutiable at the rate of 25 per cent. *ad valorem* as a chemical compound, under the provisions of paragraph 3 of the Act of July 24, 1897, was reversed by a decision of the United States Circuit Court for the Southern District of New York, in the case of Gabriel & Schall *v.* United States (T.D. 24,331), which held that said article was free of duty under the provisions of paragraph 489 of said Act, for "baryta; carbonate of, or witherite." The department is now of the opinion that "witherite" being a narrower and more particular term than "carbonate of baryta," and being included therein, the inclusion of the words "or witherite" in said paragraph would be superfluous and without meaning, unless the same be interpreted to limit the barium carbonate therein provided for to the form thereof known as witherite.

Duty is, therefore, to be assessed upon precipitated barium carbonate at the rate of 25 per cent. *ad valorem* under paragraph 3 of the Act of July 24, 1897.

This ruling will apply only to merchandise exported after July 26, 1906.

Carbon dioxide; Production of ——, in the United States. Oil, Paint, and Drug Rep., Aug. 6, 1906. [T.R.]

THERE are now about 40 factories producing liquefied carbon dioxide in the United States, the annual output amounting to about 30,000,000 lb.

Although carbon dioxide occurs in almost every natural water, it is rarely present in quantities sufficient for commercial purposes. It is only at Saratoga Springs, New York, that practical use is made of it in the United States in the production of liquefied acid. To meet the increasing demand, over 40 wells, generally 6 ins. in diameter and ranging from 30 to 300 ft. in depth, have been drilled to secure the carbon dioxide gas, the total yield of which is estimated at about 20,000 lb. per day. It is reported that a considerable proportion of the 20,000 lb. is obtained from the drift into which it has passed from the underlying rocks, only about half of which is recovered. The largest producers, therefore, are said to be the relatively shallow wells, 30 to 100 ft. in depth, of which many have been drilled south of the town. Of the rock wells, those south of the town yield the most gas, at depths from 150 to 600 ft. The rock gas, if found at all in commercial quantities, is generally encountered at the junction of the argillaceous Utica shale just over the Trenton limestone. Many wells have been drilled which have proved non-producing.

Compression of the gas.—From the wells the water and associated gas are piped to a separator, a large tank equipped with a 2-ft. trap at the bottom, from which the water escapes, and with a pipe at the top leading to the gasometer into which the gas discharges. From the gasometer the gas is drawn through calcium chloride driers to remove the moisture, after which it passes to the compressor, working generally in three stages, at, approximately, 60, 300, and 1000 lb. After cooling, fixed weights of the liquid are admitted into cylinders for shipment.

The cylinders are made of lap-welded or seamless steel tubing; the smaller cylinders are about 5¼ ins. in outside diameter and 4 ft. long and are charged with 20 lb. of liquid, while the larger are 8½ ins. in diameter and 51 ins. long and are charged with 60 lb. This is two-thirds of the water capacity. The bursting pressure of the tubes varies between 5100 and 5900 lb. per square inch in the case of the seamless tubes and between 4900 and 5500 lb. for the lap-welded. All are tested to 3700 lb. before filling. Since the pressure, even at 55° C., is only 2240 lb., there is a wide margin of safety.

Arsenic. C. C. Schnatterbeck. Mineral Resources of the United States, 1905. [T.R.]

THE United States utilises over half of the world's production of metallic arsenic, arsenious oxide, and arsenic sulphides. Every year several hundred tons of arsenic sulphide, obtained in purifying sulphuric acid, are wasted. An economical method of treating this arsenious by-product is needed. In addition to the arsenic recovered from arsenical pyrites mined in Washington and from the ores which occur in Virginia, attempts are being made to recover the arsenic which is going to waste in the smelter fumes at Anaconda, Mont.

In 1905 there was produced in the United States 1,507,386 lb. of arsenious acid, valued at $35,210, as compared with 72,413 lb., valued at $2,185, in 1904.

Production of arsenic in the United States, 1901—1905.

[Pounds.]

Year.	Quantity.		Value.
1901	600,000	..	$18,000
1902	2,706,000	..	81,180
1903	1,222,000	..	36,691
1904	72,413	..	2,185
1905	1,507,386	..	35,210

Imports of metallic arsenic, white arsenic (arsenious oxide), and arsenic sulphides (orpiment and realgar) into the United States, 1900—1905.

[Pounds.]

Year.	Quantity.		Value.
1900	5,765,559	..	$265,500
1901	6,989,668	..	316,525
1902	8,110,898	..	280,055
1903	8,357,661	..	294,602
1904	6,800,235	..	243,380
1905	7,675,088	..	256,540

A noteworthy feature of the industry has been the growth in the production of Spain, a country which shipped to the United States in 1905 approximately 1750 short tons of white arsenic, containing 99·8 per cent. of arsenious oxide. The largest producer of metallic arsenic and arsenious oxide in the world is Germany, by far outclassing Great Britain, which until 1902 held first place among the producing countries. Hopes are entertained that Canada may become an important producer through the development of its new deposits of mispickel in Ontario. As for the United States, there are signs that the domestic production of arsenic will show marked expansion in the near future.

The world's annual production of arsenic, 1901—1905

(d) Arsenic sulphide; in addition to these quantities, during 1903 there were produced 22 tons of orpiment valued at $3,337.
(e) Arsenious oxide.
(f) Not reported.

Monazite sand. Eng. and Min. J., July 21, 1906. [T.R.]

THE total European demand for monazite sand, including that exported from Europe to America, is 1200 to 1500 metric tons per year. Brazil alone can supply 10,000 tons easily, which exceeds all possible consumption. However, prospecting for new sources of supply is being actively carried on, and not without success. The result is that the monazite sand business will before long cease to be remunerative, and even now, owing to contracts, the stocks in Europe are sufficient to inundate the markets at any moment. In such circumstances, observes "La Nature," June 9, the German Thorium Convention is not likely to be renewed on its expiry in 1907.

ENGLISH PATENTS.

Nitric acid or the salts of nitric acid; Utilisation of the nitrogen of the air by the oxidation of the same, and conversion of the product into ——. O. H. U. Brünler, Leipzig-Gohlis, Germany. Eng. Pat. 5901, March 10, 1906.

A MIXTURE of oxygen and nitrogen, together with combustible gases, is passed under pressure into a combustion chamber, disposed in a closed vessel containing water. The gases are ignited within the furnace, the proportion of the constituents and the pressure being so adjusted that a temperature of about 2500° C. is attained. The burning gases issue from an opening in the bottom of the combustion chamber, in the form of a pointed flame, which shoots down into the water in the containing vessel, and becomes enclosed by an envelope of superheated steam. Under these conditions, the production of nitric acid may, it is stated, be carried on as a profitable process, as the steam is decomposed into its elements, and "furthers the chemical action by the formation of new combinations." Instead of pure water, a saline solution, such as of sodium chloride, may be used as absorber, in which case sodium nitrate is formed. (Reference is made to Eng. Pat. 5540 of 1904; this J., 1905, 276.)—E. S.

Sulphate of ammonia; Apparatus for making ——. S. H. B. Langlands, Glasgow, and H. O'Connor, Edinburgh. Eng. Pat. 17,267, Aug. 26, 1905.

THE saturator and draining tray are made of porcelain, glazed earthenware, or the like, being constructed in parts, which are connected by means of suitable holes or lugs contained in or projecting from them, through which holes, bolts, preferably made of lead, are passed.—E. S.

UNITED STATES PATENTS.

Sulphuric acid; [Electrolytic] Method of making ——. W. M. Johnson. U.S. Pat. 825,057, July 3, 1906. XIA., page 816.

Alumina; Process of manufacturing ——. H. C. Peffer, East St. Louis, Ill., Assignor to the Pittsburgh Reduction Co., New Kensington, Pa. U.S. Pat. 826,354, July 17, 1906.

BAUXITE is heated with lime or other compound of calcium, to produce calcium aluminate, which is digested with a solution of sodium carbonate. From the filtered solution of sodium aluminate thus obtained, alumina is precipitated by a current of carbon dioxide.—E. S.

Leaching solutions; Process of treating acid ——. P. F. Cowing, Assignor to P. de P. Ricketts, New York. U.S. Pat. 825,302, July 10, 1906.

PYRITES containing iron as well as metals capable of being precipitated from a mineral acid solution by hydrogen sulphide, is fused out of contact of air and in presence of metallic iron. The fused product, containing metal sulphides, is subjected to the action of an "acid leaching solution containing a metal whose sulphide is insoluble in the acid in the presence of hydrogen sulphide," during the evolution of which the iron dissolves, whilst the other indicated metals in the product and in the leaching solution are precipitated, or remain undissolved.—E. S.

Potassium chloride; Extracting —— from seaweed. D. M. Balch, Assignor to A. P. Stephens, Coronado, Cal. U.S. Pat. 825,953, July 17, 1906.

THE seaweeds are "sweated," and dried in an enclosure, and the exuded salts are then separated by mechanical agitation. (Compare U.S. Pat. 794,481 of July 11, 1905; this J., 1905, 883.)—E. S.

FRENCH PATENT.

Organic or inorganic compounds; Process for the reduction of ——. S. Kapff. Fr. Pat. 362,985, Feb. 3, 1906. Under Int. Conv., Feb. 8, 1905.

FORMIC and sulphurous acids, or their compounds, are used in combination to effect reductions, which, in many cases, neither reagent, taken separately, can realise. For example, on heating a mixture of water, sodium formate, sodium bisulphite, and hydrochloric acid, with nitrobenzene, aniline is produced. Thus also, an aqueous solution of sodium bisulphite and formic acid reduces Indigo Carmine on heating. Solution of ferric chloride may be reduced by the same reagents. Many examples are given of the application of this reducing compound in discharging the colours of certain dyes on cotton, silk, &c., and for the reduction of ferric salts, in the cellulose industry, &c.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page 760.*)

Smalt; Defects of —— in the salt-glazing kiln. W. Scheller and O. Geiz. Sprechsaal, 1906, **39**, 420; Chem.-Zeit., 1906, **30**, Rep. 239.

THE addition of a highly fusible frit to the pigment, in order to fuse the particles of smalt that are liable to volatilise in the salt-glazing kiln and produce irregular colouring of the ware (stoneware), is insufficient to obviate the defect at the places where the salt comes most in contact with the ware when thrown into the kiln, and it is therefore better not to place any blue ware in those parts of the kiln. The following mixture is recommended as a frit for smalt: $(0{\cdot}2K_2O,0{\cdot}2Na_2O,0{\cdot}6CaO)1{\cdot}8—2SiO_2$.
—C. S.

Stoneware glaze. E. Berdel. Sprechsaal, 1906, **39**, 402; Chem.-Zeit., 1906, **30**, Rep. 239.

A LEADLESS glaze, rich in alumina and silica, and suitable for use on stoneware to be fired at a finishing heat corre-

sponding to Seger cone 1—3, can be obtained by fritting Norwegian felspar 55·6 parts, calcined borax 50·5, marble or calcspar 20, and quartz sand 54 parts. Of this frit 170 parts are ground with 55·6 parts of felspar, 29·6 of barium carbonate, 20 of marble, 22·2 of calcined kaolin, 25·8 of raw kaolin, and 42 of quartz sand. The glaze may be coloured with metal oxides, preferably added to the fritting charge.—C. S.

FRENCH PATENT.

Glass articles; Staining ——. R. Kessler. Fr. Pat. 362,972, Feb. 3, 1906.

FOR colouring hollow beads, artificial fruits, and other similar articles of glass, a mixture is used consisting of powdered aluminium and gelatin, to which an aniline colouring matter is added.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 760.)

Portland cement; Influence of added substances on the strength of ——. Wormser. Tonind. Zeit., 1906, **30**, 949; Chem.-Zeit., 1906, **30**, Rep. 239.

IN order to ascertain whether any increase of strength could be imparted to a mixture of cement and sand (1:3), by the addition of acids and saline solutions that form insoluble or sparingly soluble compounds with lime, test blocks of cement prepared in (*a*) rotary tube furnaces, (*b*) shaft furnaces, and (*c*) ring furnaces, were treated with oxalic acid, chromic acid, or phosphoric acid, or the sodium or ammonium salts of these acids; also with ammonium fluoride, sodium silicate, borax, or boric acid, in solutions of varying concentration. The cements (*b*) and (*c*) gave better results than when mixed with water alone, especially after standing for 28 days, but only a slight increase of strength was exhibited by (*a*).—C. S.

Portland cement; Influence of sulphates on the setting properties of ——. L. Périn. Le Génie Civil, Paris, **46**, 390—391. Proc. Inst. Civil Eng., 1905—1906, **163**, 54.

THE author determined the rate of setting of (1) plaster of Paris; (2) Portland cement; and (3) mixtures of Portland cement with quantities of different substances containing equal amounts of sulphuric anhydride, viz., (*a*) with 1 per cent. of plaster of Paris; (*b*) with 1·12 per cent. of raw gypsum; (*c*) with 1·54 per cent. of potash alum; and (*d*) with 0·86 per cent. of ammonium sulphate. It was found that the retarding effect of plaster of Paris was identical with that of raw gypsum, but less than that of ammonium sulphate; the addition of alum had practically no effect. The author expresses the opinion that the retarding action is due to chemical causes, and depends, within limits, on the quantity of sulphuric anhydride present. The increased action of ammonium sulphate is considered to be due to the relative instability of that compound, whilst the negative result, obtained with alum, is probably due to the presence of aluminium in that salt.—A. S.

UNITED STATES PATENT.

Cement; Apparatus for manufacturing ——. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 825,305, July 10, 1906.

THE apparatus consists of a rotary kiln with a blast gas-burner or other fuel-feeding arrangement at its lower end, and a housing enclosing its upper end. In this housing are placed baffle-plates, which cause a deposition of dust, and force the products of combustion to adopt a circuitous route, thereby heating a number of air-flues, also placed in the housing. The dust deposited is removed through doors. From the air-flues, a connecting pipe leads the heated air to the blast burner, which is fed from a producer into which waste gases from the kiln, after traversing the housing, are delivered.—A. G. L.

X.—METALLURGY.

Slags; New apparatus to determine the melting points of ——. W. McA. Johnson. Electrochem. and Metall. Ind., 1906, **4**, 262—263.

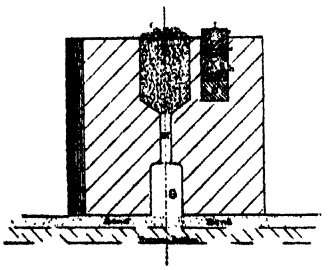

FIG. 1.

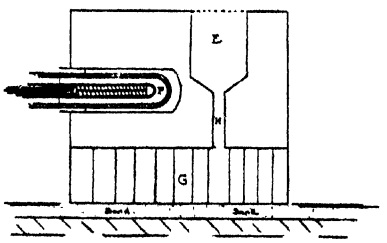

FIG. 2.

A PIECE of a round 4-in. bar of Acheson graphite, 3½ ins. long, has a narrow slot, G, $\frac{5}{8}$ in. wide and 1½ ins. high, cut in its bottom (see Fig. 1). In the top of this block a hole, E, of 1 in. diam. (Fig. 2), is drilled to a depth of 1 in., and this is continued by a hole, H, $\frac{1}{2}$ in. diam., to the narrow slot. A horizontal 1-in. hole is drilled above the level of the slot, to receive a Le Chatelier pyrometer, P, to a point as near as possible to the $\frac{1}{2}$ in. "dripping hole." A small quantity of the slag, or of the mixture of slag-forming materials, is placed in the upper hole, E, and the whole is placed in an oil-fired experimental reverberatory furnace having a layer of sand on the hearth. The pyrometer is inserted through a hole in one side of the furnace, whilst through an opening in another side, the point at which the slag drops through the hole, H, into the slot, G, is observed. It is stated that results agreeing within 5° C. can be obtained.—A. S.

Zirconium and titanium; Silicides of ——. O. Hönigschmid. Compt. rend., 1906, **143**, 224—227.

THE reduction of zirconium or titanium oxides or of their double potassium fluorides with aluminium gives, in presence of a large excess of silicon, the silicides, $ZrSi_2$ and $TiSi_2$, respectively. They are purified in the same manner as thorium silicide (this J., 1906, 481). These silicides are obtained as minute hard iron-grey crystals. The zirconium compound has the sp. gr., 4·88, and burns when heated in oxygen; the titanium compound has the sp. gr., 4·02, and is oxidised with difficulty. Both compounds are unaffected by acids (excepting hydrofluoric acid), but decompose readily when fused with caustic potash.—F. SODN.

Lead and calcium; Alloys of ——. L. Hackspill. Compt. rend., 1906, **143**, 227—229.

BY melting together lead chloride and metallic calcium, alloys of lead and calcium are formed (compare this J., 1906, 124), but the yields are poor. The alloys are harder

than lead, and tarnish rapidly. Water decomposes them with disintegration.

A crystallised compound or alloy, Pb_3Ca_2, melting at 775° C., and of sp. gr., 7·6, is obtained by distilling off the excess of lead contained in the crude alloy *in vacuo* at about 1000°.—F. Sodn.

Iron; Chemistry of ——. H. von Jüptner. Ber., 1906, 39, 2376—2402.

A lecture, summarising the present position of our knowledge of the chemistry of the iron-carbon, iron-silicon, and iron-phosphorus compounds in iron and steel.—J. T. D.

Silicon and graphite; Influence of —— *on the open-hearth process.* A. S. Thomas. Iron and Steel Inst., July, 1906 [Advance proof].

In making "acid" steel, the author finds that to obtain the best results, the pig-iron used should contain from 1·25 up to 2 per cent. of silicon; with less than this, the "banks" are invariably fluxed, whilst with more, bad "bottoms" often occur, and he suggests that in furnaces making acid steel with low silicon iron, the acid bottoms now used should be replaced by basic bottoms. He also finds that by using iron with a high percentage of combined carbon, instead of highly graphitic iron, the output is increased by 25 per cent., whilst the wear and tear of the furnace is reduced 100 per cent. When using high graphitic iron less than 10 per cent. of the carbon contents are eliminated during the melting period. In all cases the metal must be kept covered with a proper quantity of slag which is not thick and viscous.—J. H. C.

Siemens-Martin furnace; Chemical reactions in the —— Deslandes. Bull. Soc. d'Encourag., Revue de Metall., 1906, 3, 213—222.

The author has studied the "coefficients of distribution" of various elements (*i.e.*, ratio of percentages in slag and in metal) after fusion in the furnace, when equilibrium may be supposed to have been attained. These coefficients depend on the temperature, and on the composition of slag and of metal. The composition of the metal is sufficiently characterised by its content of carbon, that of the slag by its content of silica.

Silicon.—If the percentage of silica in the slag be plotted as abscissæ, (x), and that of carbon in the metal as ordinates, (y), then for metals containing from 0·15 to 0·50 of carbon, and slags containing 45 to 56 of silica, the line $x+28{\cdot}25y=59{\cdot}6$ separates the diagram into two regions—where $x+28{\cdot}25y>56$ the metal contains silicon, and in the other region it contains none. Whether the silica in the slag be saturated by iron or manganese makes no difference. Elevation of temperature favours retention of silicon in the metal, but the influence of temperature is only slight. Equilibrium is long in being attained, or in being re-established if disturbed by addition of silicon to the metal. Additions to the slag much more rapidly adjust themselves.

Manganese.—For percentages of carbon, from 0·55 to 0·20, and of silica from 59 to 53, if $x+44y>30{\cdot}8$ the metal will contain more than 0·2 per cent. of manganese—if $x+44y<30{\cdot}8$ the manganese will be below 0·2 per cent. Here, too, temperature has but a secondary influence, though high temperature favours increase of manganese. The silicon in the metal, as well as the carbon, has an influence on the manganese: if (a being the percentage of carbon, and b that of silicon) $a>0{\cdot}33+3{\cdot}4b$, the percentage of manganese depends only on the silicon, and increases with it; if $0{\cdot}33+3{\cdot}4b>a>0{\cdot}12+0{\cdot}9b$, the content in manganese depends on and increases with both carbon and silicon; if $0{\cdot}12+0{\cdot}9b>a$, the content in manganese depends only on the carbon, and increases with it. Thus, while the metal as a whole may not be in equilibrium with the slag, internal equilibrium in the metal among carbon, silicon, and manganese, may exist.

Sulphur.—This has not been fully worked out, but the coefficient of distribution seems to diminish as the basicity of the slag (especially the basicity in manganese) increases. High temperature favours the elimination of sulphur.

—J. T. D.

Copper; Solidification of ——. P. Dejean. Bull. Soc. d'Encourag., Revue de Metall., 1906, 3, 149—158.

The author has determined the temperature of solidification of copper by a thermo-electric pyrometer, comparing the indications of the same instrument given by each sample of copper with those given by gold. Assuming that the solidifying point of gold is known to be 1065° C., his conclusions are as follows:—

1. Pure copper solidifies at 1085° C.

2. It forms with cuprous oxide a eutectic containing 4·5—5·0 per cent. of oxide.

3. This eutectic solidifies near to 1065° C. The solidifying point falls slightly as the percentage of oxide is reduced, probably through impurities in the copper, which are all dissolved in the oxide.

The solidifying point of copper may be used to calibrate a thermo-electric pyrometer. For this purpose it is best to melt the copper in an open crucible; the oxidation during the time of experiment will give 2 to 3 per cent. of oxide, and the mixture will usually show two points of arrest on cooling. The temperature of the second arrest may be taken as 1062° C.—J. T. D.

Brasses; Special ——. L. Guillet. Bull. Soc. d'Encourag., Revue de Metall., 1906, 3, 159—204.

A more detailed memoir than that abstracted in this J., 1906, 540. The chief additional points are as follows:—

Ordinary brasses.—Those containing 48—55 per cent. of copper, consist chiefly of the constituent β, which is forgeable hot; yet brasses with less than 55 per cent. of copper are rarely met with industrially. This is, perhaps, because (1) they are hard and difficult to work; (2) the interval of temperature over which they can be rolled or hammered is restricted, and would be difficult to maintain in practice. Moreover, small amounts of impurities have an important influence on the mechanical properties; the author's experimental brasses were all made from pure materials, which could not be used industrially.

Brasses containing Aluminium.—Aluminium can be added to brass to the extent of about 10 per cent. before it forms a special constituent. The properties of the alloys are closely similar to those of the "equivalent" ordinary brass (*i.e.*, having really the "imaginary" percentage of the alloy), but the elastic limit is distinctly higher in the aluminium brass than in the equivalent ordinary brass. In alloys with the same "imaginary" percentage of copper, the elastic limit and hardness rise, the elongation, reduction in area, and resistance to shock fall, as the percentage of aluminium increases.

Brasses containing manganese.—It needs 8 per cent. of manganese in an alloy containing 60 per cent. of copper, before a sensible amount of a special constituent is formed; and with higher percentages of copper, even 15 per cent. of manganese shows no trace of it. Manganese brasses resemble in properties the equivalent ordinary brasses, but the elastic limit and breaking stress are considerably raised. Manganese alloys with the same "imaginary" percentage of copper, but different percentages of manganese behave, as to their relative mechanical properties, like aluminium brasses. The addition of manganese allows of rolling, industrially, brasses composed entirely of the constituent β.

Brasses containing iron.—The author has not investigated these very fully. Up to 1·66 per cent., iron produces very little effect on the mechanical properties; the breaking stress is slightly lowered, the hardness increased.

Brasses containing tin.—Tin dissolves first in the constituent α; the more zinc this contains the less tin can it dissolve. When the α-constituent is saturated, the tin forms a special constituent, similar to that found by Heycock and Neville in bronzes. In brasses containing both the α and β constituents, the α-constituent first takes up about 0·7 per cent. of tin, then the β-constituent an equal percentage, then the special constituent begins to be formed, first at the expense of the β-solution, and, when that is all absorbed, at that of the α-solution. An amount of tin not more than necessary to saturate the α and β solutions has but little effect on the mechanical properties, but when it exists

in greater quantity it is injurious. Brasses with these higher proportions of tin are, however, much more resistant to sea-water than ordinary brasses.

Brasses containing lead.—Lead dissolves to the extent of about 0·9 per cent. in both the α and β solutions, and in that condition is almost without effect; but in larger amount, when it exists as lead, it rapidly lowers the mechanical qualities of the alloy.

Brasses containing silicon.—The solution β can dissolve more silicon as its zinc content is lower—1·4 per cent. at 63 per cent. of copper, 2 per cent. at 90 per cent. of copper. The solution β dissolves about 1·4 per cent. Higher percentages give rise to a special constituent similar to one found in industrial copper-silicons. The properties of silicon brasses not containing the special constituent are very similar to those of the equivalent ordinary brasses, but the elastic limit is raised. When the special constituent forms, the mechanical qualities undergo rapid degradation.

Brasses containing magnesium.—Not more than 0·2—0·3 per cent. of magnesium can be dissolved without formation of a special constituent which is highly injurious. Magnesium must, therefore, be used very sparingly and carefully, if used at all, for deoxidising brasses.

Antimony behaves, as regards its solubility and its effects, almost identically with magnesium.

Complex brasses.—When more than one substance is added to a brass, each behaves as though it were the only substance added.—J. T. D.

Metallic alloys compounded in atomic proportions; Physical properties of —— at ordinary and higher temperatures. W. Rubel. Ann. Gewerbe- u. Bauw., 1906, **59**, 9; Chem.-Zeit., 1906, **30**, Rep. 243.

SMELTING furnaces with natural draught give alloys of better quality, with less waste, than when artificial draught is employed, owing to the smaller excess of oxygen in the former. The conductivity of copper smelted under the first-named conditions was found to be 110 per cent. (referred to standard copper), whilst in the other case it was only 73 per cent.

An alloy with the composition Cu_2Fe_2NiAl gave the tensile strength 82 kilos. per sq. mm. with only 3 per cent. of elongation, perfectly uniform structure, and only two constituents (α- and β-crystals), no eutectic being formed. The elongation increased to 13 per cent. (in the quickly cooled state) on altering the proportions in such ratio as would correspond to $Cu_2Fe_2Ni_2Al$, the tensile strength being 75·7 kilos. per sq. mm.; surface of fracture, copper red; worked surface, the colour of nickel; cost of production and resistance to the action of chemicals, both high. An alloy of the composition Cu_2Zn was melted with a small proportion of the foregoing, and gave a product with the tensile strength of 48·7 kilos. per sq. mm., elongation 31 per cent., limit of elasticity 20 per cent., fusing point 950° C. Tin is unsuitable for alloys of the kind under consideration that are to stand strain up to 250° C., and manganese quite unsuitable for such as are to be exposed to high temperatures.—C. S.

Copper Mining in Japan. Eng. and Min. J., July 21, 1906. [T.R.]

ACCORDING to recent advices, the copper-mining industry of Japan is in a very prosperous condition, and the production of the important mines is rapidly increasing. The chief feature of the recent history is the remarkable development of the Kosaka mine, in the northern part of the island of Nippon. This property was originally worked as a silver mine, but in passing below the line of oxidation, the ore changed into an enormous mass of mixed sulphides.

The Kosaka ore deposit appears to be a blanket vein, dipping at an angle of about 45°. The hanging wall is an andesite tuff; the foot wall is diorite. The deposit is about 400 ft. in thickness, measuring at right angles to the dip of the vein. Immediately under the hanging wall is a large zone of mixed sulphides, so closely mingled that mechanical separation is impossible. This ore averages 40 to 45 per cent. of barium sulphate, 10 per cent. of zinc, 10 per cent. of lead, 2 per cent. of copper, 0·02 per cent. of silver, and a trace of gold. Immediately under it is a zone of iron pyrites containing 1 to 2 per cent. of copper, and below the latter occurs siliceous ore containing from 1 to 1·5 per cent. of copper.

The three kinds of ore are mined, and mixed in such proportion as to produce a self-fluxing product. This is smelted semi-pyritically, about 2 per cent. of anthracite being employed as fuel. Smelting is done in six furnaces, each 3·5 by 25 ft. at the tuyères. These furnaces reduce the charge at the rate of about 3 tons per square foot of hearth area per 24 hours. The slag is essentially a silicate of iron and baryta. A new furnace, 3·5 by 60 ft., is now being erected. The product of the blast furnaces is a lead-copper matte containing about 30 per cent. of copper. This is crushed, roasted, and smelted for blister copper in reverberatory furnaces. The blister copper is refined electrolytically, and the capacity of the refinery is now being increased so as to work the entire product of the works.

The Kosaka mine has now displaced the famous Ashio mine from the premier position among Japanese copper producers. Its output last year was approximately 7200 tons of copper, against 6600 tons from the Ashio mine, and 5500 tons from the Besshi mine.

Mineral production of Bosnia. Eng. and Min. J., July 21, 1906. [T.R.]

THE mineral production of Bosnia and the Herzegovina for the year is reported as below, in metric tons:—

——	1904.	1905.	Changes.
Iron ore	127,297	122,540	D. 4,757
Copper ore	640	670	I. 30
Chrome ore	278	186	D. 92
Manganese ore	1,114	4,129	I. 3,015
Pyrites	10,421	19,045	I. 8,624
Coal	483,617	540,237	I. 56,620

The Bosnian coal is all lignite, and is obtained from a few mines.

The metal production of all kinds was as follows, also in metric tons:—

——	1904.	1905.	Changes.
Mercury	8	10	I. 2
Copper	115	39	D. 76
Pig iron	47,678	43,074	D. 4,604
Castings	3,211	3,951	I. 740
Steel ingots	24,111	29,644	I. 5,533
Wrought iron	19,622	23,200	I. 3,578

The steel made is all open-hearth steel. The decrease in iron was due to the partial suspension of the Vares works.

Nickel; Production of ——. Ch. of Com. J., Aug., 1906. [T.R.]

REPORTING on nickel production for the Ontario Bureau of Mines, Prof. A. P. Coleman says that New Caledonia is the only real competitor of Ontario as a nickel producer. Though the United States has dropped out of the race as a producer of nickel ore, it is still one of the most important countries for the refining and utilisation of metallic nickel, much the greater part of the Canadian metal being treated at Constable Hook, New Jersey. The Sudbury nickel field has long been known as the most important source of that metal in America. All the ore deposits of any economic importance are at or near the outer margin of a huge laccolithic sheet of eruptive rock a mile and a quarter thick, 36 miles long, and 17 miles wide. The rock composing this sheet is diorite at the outer and lower edge, merging into granite or granodiorite at the inner (upper) edge. The ore bodies are round the margin of the diorite, or along dike-like offsets from it. Canada is presently to have a mint, and Prof. Coleman recommends

that it should begin its work by coining 1-cent and 5-cent pieces of pure nickel, making use of a distinctively Canadian metal.

World's production of nickel.—The nickel production of the Sudbury field for the calendar year 1904 is given as 4,729 tons, valued at £302,656, and the total production of the district since the discovery of the nickel deposits there, up to and including the year 1904, at 43,877 tons, valued at £2,532,014. A table giving the world's production of nickel (in metric tons) accompanies the report. Discarding fractions of tons, this table is as follows :—

Year.	Sweden and Norway.	New Caledonia.	Canada.	United States.
1889 ..	80	1,332	377	115
1890 ..	100	1,634	651	101
1891 ..	125	2,494	1,830	54
1892 ..	97	1,606	1,095	42
1893 ..	90	2,493	1,807	22
1894 ..	90	2,422	2,226	4
1895 ..	40	2,548	1,764	5
1896 ..	20	2,707	1,541	8
1897 ..	—	2,858	1,813	11
1898 ..	—	3,648	2,503	5
1899 ..	—	4,205	2,605	10
1900 ..	—	4,526	3,211	4
1901 ..	—	5,210	4,168	3
1902 ..	—	4,024	4,850	3
1903 ..	—	4,750	6,348	52

Mercury Production in U.S.A. Oil, Paint, and Drug Rep., Aug. 6. [T.R.]

THERE was an important decline in the output of mercury during 1905. The decrease in value was even greater, due to a marked decrease in demand, the average price for the year being $36.22 per flask, as compared with $43.50 in 1904. The following is an abstract of this report :—

The production of mercury in the United States during the year 1905 amounted to 30,451 flasks (of 75 lb. net each), valued at $1,103,120, as compared with 34,570 flasks, valued at $1,503,795, in 1904, a decrease in quantity of 4119 flasks, and in value of $400,675. This output was produced by four States as follows :—California, 24,035 flasks; Texas, 4723 flasks; Utah, 1050 flasks: Oregon, 43 flasks. This falling off in production was due primarily to a lack of demand and a consequent decline in price, and also to a depletion of the richer ore produced in some of the larger mines.

California.—The amount of mercury produced in California during 1905 was 24,635 flasks, valued at $886,081, as compared with 29,217 flasks, valued at $1,270,200, in 1904. This output represents 81 per cent. of the total production of the country. The decrease of 4565 flasks in the quantity of mercury produced in California during 1905 is due rather to a lessened production of all the mines than to any serious falling off in the output of any single one, with the exception, perhaps, of the new Almaden property in Santa Clara county. This is the oldest mercury mine in the country, and for years was the largest producer on North America. Of the total output of the whole State of California during the last fifty-five years, nearly 2,000,000 flasks, fully one-half, has been produced by the New Almaden. At present the New Idria mine in San Benito county is the largest producer in the State. The Napa Consolidated, in Napa county, and the New Almaden come next as regards output. The Oceanic, the Great Western, the Great Eastern, the Socrates, the Karl, and the Altoona are the other principal producing mines of the State.

The outlook for an increased production of mercury in California is not encouraging, and a further decrease in the output for 1906 is indicated by the decline in production from 3449 flasks in January and 2526 flasks in February of 1905 to 1588 flasks in January and 1904 flasks in February of 1906—a decrease of 861 and 622 flasks respectively.

Texas.—The developments of the mercury industry in Texas during 1905 were the most important in this country. The mercury deposits are situated in the extreme south-western part of the State, about 300 miles south-east of El Paso, about 100 miles south of the line of the Southern Pacific Railway, and from 7 to 15 miles north of the Rio Grande. They lie in three areas, known respectively as Terlingua, Study Butte, and Chisos districts.

The Terlingua district comprises an area of about 25 square miles in the immediate vicinity of Terlingua. The Study Butte district embraces about six square miles about ten miles east from Terlingua. The Chisos district, the last discovered and the least developed, lies immediately east of the districts mentioned, and south-east of the Chisos mountains.

The mining methods employed in this region are extremely crude. The deepest shaft in the region is down only about 300 ft. in limestone. The shales have been penetrated only to a depth of 200 ft.

The production of mercury in Texas during 1905 was 4723 flasks, valued at $173,302, as compared with 5336 flasks in 1904, valued at $232,116, a loss of 613 flasks in quantity and of $58,754 in value. This output for 1905 represents 15·53 per cent. of the total production of the country. The decrease in the output was in a large measure due to a very heavy decline in the price of mercury

Prices.—During 1905 the price of mercury suffered a heavy decline, due to a marked decrease in demand. The average San Francisco price for the year was $36.22 per flask of 75 lb. Corresponding average quotations were $44.10 per flask in 1902, $45.29 in 1903, and $43.50 in 1904. In San Francisco wholesale quotations of mercury for domestic delivery ranged from $37 to $42 per flask, and metal for export was quoted at $35 to $41. In New York prices were $38 to $42.50 per flask, and in London from £7 2s. 6d. to £7 12s. 6d. per flask.

Imports.—There is an import duty of 7 cents per lb. on mercury, which is sufficient practically to prohibit importation. During the past five years the value of the product imported has ranged from $789 to $2166. The quantities are not stated.

Exports.—The exports of mercury from the United States during 1905 were 1,009,444 lb., as compared with 1,611,635 lb. in 1904, a decrease of 602,191 lb., or 37·4 per cent.

Mineral production of Tasmania in 1905. Bd. of Trade J., Aug. 9, 1906. [T.R.]

THE following statistics of the mineral production of Tasmania during the years 1904 and 1905 are taken from the report for 1905-06 of the Hobart Chamber of Commerce :—

		Quantity.		Value.	
		1904.	1905.	1904.	1905.
				£	£
Copper (blister)*	Tons	8,371	[8,610	582,540	704,287

ENGLISH PATENTS.

Smelting ores in blast furnaces; Method of and means for ——. W. Kemp, Tucson, Ariz., U.S.A. Eng. Pat. 20,961, Oct. 16, 1905.

SEE Fr. Pat. 358,645 of 1905; this J., 1906, 270.—T. F. B.

Furnaces for re-heating and like purposes. H. Hart, Rotherham, Yorks. Eng. Pat. 19,670, Sept. 29, 1905.

THE furnace is supplied with means for preheating the air needed for combustion, consisting of a culvert built below the furnace floor level, extending from the firing end down one side to the opposite end or thereabouts, crossing over, and returning down the opposite side, where it terminates in a nozzle directed under the fire-grate. The entrance end of the culvert is provided with a regulating valve; air is blown into it by a fan or blower; and baffle-walls may be placed in it. The firing-hole and the ash-pit are made with suitably closing doors. —A. G. L.

[*Jig-washing machine.*] *Mineral washing and separating apparatus.* R. M. Howatt, London. Eng. Pat. 7541, March 28, 1906.

A NUMBER of jig compartments are placed around a refuse chamber common to all the jig compartments, and from which the refuse received is removed by a suitable elevator. The whole is preferably made in the form of a V-shaped tank, the jig compartments forming smaller V-shaped chambers along the two upper edges of the tank, and being provided with suitable valves to drop the refuse into the common central channel. Lateral channels may also be provided between the compartments to allow of the removal, by means of valves, of refuse collected above the sieves in the compartments.—A. G. L.

Alloy for bearings or the like. Siemens und Halske A.-G., Berlin. Eng. Pat. 10,513, May 4, 1906. Under Int. Conv., Sept. 22, 1905.

THE alloy consists of approximately equal parts of cadmium and zinc, to which up to 10 per cent. (but preferably only 5 per cent.) of antimony is added. It is claimed that this alloy is easily worked and turned, fills the moulds completely, possesses relatively great hardness, and has a very small coefficient of friction. —A. G. L.

UNITED STATES PATENT.

Furnace; Tilting ore-roasting ——. T. Edwards, Ballarat, Australia. U.S. Pat. 825,446, July 10, 1906.

THE furnace comprises a long ore-roasting chamber disposed above, and connected with a heating chamber. The ore chamber is provided with a series of rabbles, and the heating chamber is divided by a longitudinal partition, to provide a circuitous path for the hot gases. Both of the chambers discharge into a flue at one end of the furnace, and dampers are provided so that the gases from the ore-roasting chamber can pass either directly into the flue, or first into the lower heating chamber and thence into the flue.—A. S.

FRENCH PATENTS.

Zinc; Manufacture of ——. R. Fritsch and E. Nonnast. Fr. Pat. 363,036, Feb. 6, 1906.

BEFORE being distilled, the mixture of zinciferous mineral and carbonaceous material is first moulded into blocks corresponding with the cross-section of the retort. The moulding may be done by adding binding agents, or in the hydraulic press, or by a combination of the two methods. It is claimed that this invention facilitates charging of the retorts, and enables from 35 to 40 per cent. more material to be distilled in one operation.—A. G. L.

Gold, platinum, silver, nickel, and copper; Wet method of extraction of ——. A. Seigle. Fr. Pat. 363,039, Feb. 6, 1906. Under Int. Conv., Feb. 6, 1905.

THE invention consists essentially in extracting metals from their ores by subjecting the finely powdered mineral to the action of steam under pressure in the presence of silicic acid (or boric acid) and a solution of chloride of sodium, calcium, or magnesium. The operation is carried out in a suitable autoclave provided with stirrers under a steam pressure of 3 kilos. per sq. cm. If the ore itself is not sufficiently siliceous, a suitable amount of silica (or boric acid) is added to it. In extracting copper and nickel, the ore is first gently roasted; if much sulphur or arsenic is present, a little ferrous sulphate is added to the sodium (or other) chloride used in the extraction. The copper and nickel go into solution as more or less complex chlorides, and are recovered in any usual way. If a silver ore is to be treated, sufficient sodium chloride must be present to dissolve the silver chloride formed. Comparatively rich gold and platinum ores are treated with sodium chloride and nitrate, the nascent chlorine produced being said to be specially active in dissolving the precious metals. Poor gold ores and residues are first treated with a solution of potassium ferrocyanide through which air is blown, after which the whole mass is treated with steam under pressure in an autoclave.—A. G. L.

(*A.*)—ELECTRO-CHEMISTRY.

Ozone; Influence of pressure and the character of the discharge on the formation of ——. A. Chassy. Compt. rend., 1906, **143**, 220—222.

THE percentage of ozone formed, when equilibrium is established, decreases slightly as the pressure is lessened, though the initial increase in concentration per unit of time is greater. Quite abruptly, however, at pressures below 60 mm., no ozone at all is produced. At these low pressures the discharge is seen as a uniform glow quite different from the appearance at higher pressures, and the difference in results seems to correspond with that in the character of the discharge. Ozonised oxygen below this pressure of 60 mm. is at once decomposed by the action of the discharge.—F. SODN.

ENGLISH PATENT.

[*Vanadium carbide*] *Filaments for electric incandescent lamps; Impts. in* ——. The British Thomson-Houston Co., Ltd. From General Electric Co. Eng. Pat. 19,264, Sept. 23, 1905. II., page 803.

UNITED STATES PATENTS.

Furnace; Rotary electric ——. W. M. Johnson, Iola, Kans. U.S. Pat. 825,058, July 3, 1906.

THE furnace, which is mounted so that it can be rotated, consists of separate sections with insulating material between them. Each section has a lining of refractory material, and the furnace is heated by a resistance body of divided conducting material embedded in the linings. —A. S.

Sulphuric acid; [Electrolytic] Method of making ——. W. M. Johnson, Iola, Kans. U.S. Pat. 825,057, July 3, 1906.

A SOLUTION of sulphuric acid containing sulphur dioxide is electrolysed by means of electrodes connected in series, the anode faces of the electrodes being composed of lead, and the cathode faces of a metal, such as electro-deposited copper, having a low cathode potential. When the

concentration of sulphuric acid in the solution has increased to the desired extent, a portion is withdrawn, the remainder is diluted, a further quantity of sulphur dioxide is introduced, and the electrolysis is repeated.—A. S.

Calcium carbide; Producing ——. J. M. Morehead, Chicago, Ill. U.S. Pat. 825,234, July 3, 1906.

The charge is fed downwards into a region of reduction established under a gas-tight hood depending into the furnace chamber, the lower end of the hood and the upper end of the furnace chamber being sealed by the charge material. The waste gases are withdrawn from the hood. —E. S.

Lead into lead sulphate; [Electrolytic] Method of converting spongy ——. C. J. Reed, Philadelphia, Pa., Assignor to Security Investment Co. U.S. Pat. 825,981, July 17, 1906.

This invention relates to a method of converting the spongy or finely-divided lead, of a negative pole secondary battery electrode, into lead sulphate, and consists in connecting the same in a closed circuit with an electrode of electro-negative material, having a coating or deposit of platinum black or finely-divided platinum, in a bath of dilute sulphuric acid. A similar method of reversing a spongy-lead electrode and charging the same as a peroxide plate is also claimed.—B. N.

Nitrogen compounds; Electrochemical process of producing ——. J. W. Wood, Moulton, Iowa. U.S. Pat. 826,301, July 17, 1906.

This invention relates to an electrochemical process for making nitrogen compounds, and consists in continuously charging a liquid electrolyte, such as "an aqueous solution of nitrogen," with air under pressure in order to furnish it with an excess of nitrogen. The liquid is subjected to the action of an electric current in order to dissociate the water, and the nitrogen and other compounds formed are finally carried off at the anode and cathode respectively. —B. N.

(*B.*)—ELECTRO-METALLURGY.

Ferrosilicon manufactured in electric furnaces; Phosphuretted hydrogen poisoning from ——. P. Lehnkering. Z. Unters. Nahr. und Genussm., 1906, **12**, 132—135.

In investigating the cause of death of two children upon a Rhine boat carrying ferro-silicon, the presence of some 0·15 per cent. of phosphorus in the 57·69 per cent. silicon alloy was determined. The product, which had already been exposed somewhat to rain, was only examined some five or six days after the loading of the vessel, but still evolved 0·0227 grm. of hydrogen phosphide per kilo. in contact with water. The evolution of this gas is ascribed to the presence of calcium phosphide, iron phosphide being stable in presence of water. The cabin occupied by the children for two or three days continuously was situated over the hold in which the kegs of ferrosilicon were stored.

Mention is made of several other cases of sudden death on Rhine boats during the last six months, and to the explosions at Liverpool (this J., 1904, 324 and 622), which may probably also be ascribed to phosphuretted hydrogen. —R. S. H.

Strontium amalgams. A. Guntz and G. Rœderer. Bull. Soc. Chim., 1906, **35**, 494—503.

By the electrolysis of a saturated solution of strontium chloride, using mercury at the cathode, the authors have succeeded in obtaining crystals, in large quantity, of an amalgam $SrHg_{11}$, the existence of which had been disputed. The electrolysis was carried out at 20 volts and 1—1·5 ampères per sq. cm. of cathode, and the temperature was maintained at 20°—30° C. by special cooling arrangements. The crystals, which contain 3·8 per cent. of strontium, change rapidly in the air, and are easily decomposed by water. They may be preserved, however, in an atmosphere of dry carbon dioxide. No mercury is lost by subjecting them to a pressure of 5000 kilos. per sq. cm., but on heating *in vacuo*, mercury is given off, and richer amalgams are obtained. In one experiment definite crystals containing 6·8 per cent. of strontium, corresponding to the formula $SrHg_6$, were obtained. The amalgams with 6—10 per cent. of strontium are brittle, hard, and fine-grained, and are not much affected by air. Experiments at high temperatures were carried out in a manner similar to those with barium amalgam (this J., 1905, 278), but pure strontium cannot be obtained, for at 1000° C., instead of a further loss of mercury, the amalgam containing about 50 per cent. of strontium, distils unchanged.—F. Sodn.

Metallic deposits; Process for obtaining electrolytic ——. L. Trunkhahn, Vienna. Eng. Pat. 11,498, May 16, 1906.

This invention relates to the production of adherent and lustrous metallic deposits by means of an electrolytic bath to which sugars are added, and consists in the addition to the same of a ferment. The following is given as an example of a zinc bath:—25 kilos. of crystallised zinc sulphate; 15 kilos. of aluminium sulphate; 1 kilo. of calcium carbonate; 4 kilos. of maltose or dextrose; 0·5 kilo. of beer barm.—B. N.

United States Patents.

Furnace; Electric ——. F. T. Snyder, Oak Park, Ill. U.S. Pat. 825,359, July 10, 1906.

This invention relates to an electric furnace of the transformer or induction type, and comprises a core contained within a chamber, the latter being adapted to hold material forming a secondary circuit about the core. A primary induction-coil winding is arranged on the core substantially concentric with the secondary, but relatively displaced along the core such a distance as to allow sufficient magnetic leakage between primary and secondary to maintain constant current in the secondary, upon the application of constant-potential alternating current to the primary winding. The laminated iron magnet core is provided with means for clamping the laminæ together, non-conducting material being disposed about an arm of the core so as to form a vertically-disposed annular chamber surrounding the core. Between the laminæ of the core is a closed trough having a transverse web, and adapted to contain water, the core projecting outside the wall of the chamber, means being provided for circulating water between the core and the chamber. The core is placed within a bridge of refractory material which extends across the central portion of the chamber, dividing the latter into two vertical wells on each side of the bridge. The secondary circuit comprises a low-resistance metal conductor consisting of multiple bars of copper passing under the core from one well to the other, and molten electrodes of the metal to be smelted are in contact with the terminals of the low-resistance conductor, the bridge separating the two electrodes. A slag containing the same metal is supported on the molten electrodes to a level above the level of the bridge, thus uniting electrically the electrodes, and ore to be smelted is fed upon the molten material through a suitable opening in the reverberatory roof of the furnace. The slag at the top offers the highest resistance, and the maximum heating effect is thus developed in the upper portion of the secondary circuit. The chamber is provided with an opening through which the quantity of material in the secondary circuit may be varied in order to vary the resistance, and the temperature of the furnace may thus be adjusted and automatically maintained constant. The resistance of the metal increases with rise in temperature, and that of the slag decreases, and the relative resistance of the metal and slag are so proportioned that the resistance of the secondary will increase with a fall of temperature in the furnace.—B. N.

Furnace; Electric ——. J. F. Hammond, Brewster, N.Y. U.S. Pat. 825,386, July 10, 1906.

The furnace consists of a muffle having its four sides and top permanently closed, and mounted on a suitable frame by means of a pivoted joint whereby the muffle can be inverted from its normal position, switch-blades, secured to the frame and muffle-body respectively, engaging when the muffle-body is swung on the frame. A bottom member, vertically movable in the frame, engages and closes the bottom of the muffle, the bottom member being reciprocated by a cam controlled by a handle-lever, rollers connected to the bottom member guiding it in the frame. Means are provided for locking the bottom when engaging the muffle. Electric coils are arranged in each of the six portions of the muffle, the coils being divided into four groups, one group, *a*, being disposed in the top, bottom, front, and back of the muffle, a second group, *b*, disposed in the bottom and top of the muffle, a third, *c*, in the front and back of the muffle, and a fourth, *d*, in the two other sides of the muffle. The terminals of the coils are connected with an electric switch in such a way that the "groups will first be connected in series, and in the successive positions of advancement of the commutator, the latter will so connect the terminals of the groups whereby in the second position a shunt of low resistance will be established around two of such groups as *c* and *d*; in the third position of the commutator the groups *c* and *d* will be out, leaving *a* and *b* in circuit; in the fourth position of the commutator groups *a* and *b* in series will be connected in parallel with groups *c* and *d* in series; in the fifth position of the commutator a shunt of low resistance will be established around group *c* in the latter multiple-series arrangement; in the sixth position the groups *a* and *b* in series will be connected in parallel with the group *d*; in the seventh position the groups *a* and *b* connected in series will be connected in parallel with group *c* and also with group *d*; in the eighth position a shunt of low resistance will be established around the group *b* in the seventh position; in the ninth position the groups *a*, *c*, and *d* will be connected in parallel; and in the tenth position the four groups *a*, *b*, *c*, and *d* will be connected in parallel.—B. N.

Nickel-copper matte; [Electrolytic] Method of treating ——. W. M. Johnson, Iola, Kans. U.S. Pat. 825,056, July 3, 1906.

The matte is treated with hot dilute hydrochloric acid, whereby a solution rich in nickel, and a residue rich in copper are obtained. The solution is freed from iron, and electrolysed to recover the nickel. The copper is recovered by "converting the residue into anodes rich in copper," and then refining the latter electrolytically, the refining solution being subsequently treated for the recovery of nickel salts.—A. S.

Ferro alloys; Process of producing low-carbon ——. E. F. Price, Niagara Falls, N.Y. U.S. Pat. 825,348, July 10, 1906.

This invention relates to a process of producing low-carbon alloys of iron, such as ferro-chromium, and consists in providing a charge containing ferro-silicon and an oxidised compound of a metal, such as chromium, which is reducible by silicon and which will alloy with iron, together with a basic flux. An electric arc is established within the charge, a considerable body of the latter surrounding the zone of reduction, and protecting the electrodes from the oxidising effect of the atmosphere. Between the electrodes is maintained the minimum potential difference requisite to effect reduction, thereby preventing loss of electric current by leakage through the charge. The resulting slag and ferro alloy are separately tapped from the furnace at different levels, and the charge mixture supplied as required.—B. N.

Metals from ores; Extracting —— by electrolytic means. A. Lénárt, jun., Buda-Pesth, Austria-Hungary. U.S. Pat. 826,435, July 17, 1906.

See Fr. Pat. 356,825 of 1905; this J., 1906, 29.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page 768.*)

Linseed oil and cake; Properties of ——, in connection with various solvents and physical conditions. A. Mitarewski. Westnik gigieni, 1906, **42**, 578; Chem.-Zeit, 1906, **30**, Rep. 241.

Oil extracted with ether, petroleum spirit, benzene or carbon bisulphide lacks the characteristic smell of linseed and of the pressed oil. In the case of the last solvent, the oil has a strong garlic smell and a dark reddish-yellow colour, the others giving it a smell of fish oil and a more or less pronounced greenish-yellow tinge. Solvents do not cause any determinable alteration in the nature of the oil and cake, except carbon bisulphide, which increases the quantity of the volatile acids, and therefore raises the saponification value. Pressed oil contains more true fat. When oil is stored, the temperature influences the degree of oxidation, which is accelerated by storage at 70° C. and also by exposure to the air, although exposure to light for 26 days was found to have little effect.—C.S.

Oil from the seeds of the berries of Rhamnus cathartica. [*Purging buckthorn*]. N. Krassowski. J. russ. phys.-chem. Ges., 1906, **38**, 144—161; Chem. Centr., 1906, **2**, 348—349.

The seeds were disintegrated, and the oil extracted by ether, and purified by treatment with light petroleum spirit and sodium carbonate solution; yield 8·85 per cent. The oil is odourless, slightly soluble in alcohol, and easily soluble in ether, chloroform, and benzene. It has the sp. gr. 0·9195 at 15°/4°; saponification value, 186; Hehner value, 95·77; iodine value, 155; Reichert-Meissl value, 0·89; and acid value, 5·64. The non-volatile fatty acids have the iodine value, 160·6; acetyl value, 25·8; and mean molecular weight, 288·9. The unsaponifiable matter contains phytosterol (0·48 per cent. of the oil), and a saturated hydrocarbon melting at 81°—82° C. (0·11 per cent.). The author detected the presence, in the volatile acids, of butyric acid, and an acid crystallising in leaflets at the ordinary temperature; in the solid acids, of stearic and palmitic acids; and in the liquid acids, of linolenic, isolinolenic, linolic, and oleic acids. The following is the probable composition of the oil:—Unsaponifiable matter (phytosterol and a hydrocarbon), 0·5%; volatile acids (butyric acid, &c.), 0·24; stearic acid, 6·00; palmitic acid, 1·12; isolinolenic and linolenic acids, 22·40; linolic acid, 35·20; oleic acid, 30·10; and glyceryl radical (C_3H_5), 4·32 per cent.—A. S.

Japanese sardine oil; New unsaturated fatty acid in ——. M. Tsujimoto. J. Coll. Engineering, Imp. Univ., Tokyo, 1906, **4**, 1—9. (See also page 798.)

Japanese sardine oil, obtained from *Clupanodon melanosticta*, T. and S. (Japanese, *ma-iwashi*), is produced in large quantities on the southern and eastern coasts of Japan. The larger portion of the oil is exported to Europe, the figures for 1905 being 2,379,267 kin. (1,430,810 kilos.), valued at 125,260 yen. Three specimens of oil, from different localities, examined by the author, varied in colour from greenish-brown to reddish-brown; all of them deposited somewhat large quantities of "stearine" at low temperatures. The following values were obtained on examining the oils:—

	Sample 1.	Sample 2.	Sample 3.
Place of origin	Chita (Aichi prefecture)	Choshi (Chiba prefecture)	Hakodaté (Hokkaido)
Sp. gr. at 15·5° C. ..	0·9347	0·9318	0·9316
Acid value	1·32	3·22	5·15
Free acids, as oleic acid	0·66%	4·13%	2·59%
Saponification value..	195·76	196·16	194·81
Iodine value (Wijs' method)	180·70	180·57	187·25
Refractive index at 20° C.	1·4803	1·4802	1·4807
Melting point of fatty acids (capillary tube method)	35·4°	36·2°	35·8°

The oil is practically free from unsaponifiable matter. From the fatty acids, a bromine addition compound was prepared by dissolving about 1 grm. in 10 c.c. of glacial acetic acid, cooling the solution, and adding excess of bromine, drop by drop. The precipitate, after being washed on a filter with a large quantity of ether, was found to have a composition corresponding to the formula, $C_{18}H_{28}Br_8O_2$. The compound is thus an octobromide, derived from an unsaturated fatty acid, $C_{18}H_{28}O_2$, which the author names *clupanodonic acid*. The yield of octobromide was from 44·24 to 47·09 per cent. of the weight of the mixed fatty acids, corresponding to a content of from 13·34 to 14·20 per cent. of clupanodonic acid in the mixed acids. The free acid was obtained from the bromine compound by treatment with zinc and alcoholic hydrochloric acid, but the yield was poor. It is a yellow liquid with a fishy odour, having the iodine value 344·42; it becomes oxidised when exposed to the air, drying completely in a few days.

No hexabromide insoluble in ether was obtained from the fatty acids; hence the occurrence of jecoric acid in the oil appears to be doubtful (compare Fahrion, Chem-Zeit., 1893, 521).—A. S.

Clupanodonic acid; Occurrence of —— in herring and whale oils. M. Tsujimoto. J. Coll. Engineering, Imp. Univ., Tokyo, 1906, **4**, 11—14.

The author found that clupanodonic acid, the most characteristic unsaturated acid of Japanese sardine oil, is also present in herring oil (*Clupea pallasi*, C. and V.: Japanese, *ni-shin*) (3·82—6·54 per cent. of the mixed fatty acids); and in whale oil (*Rhachianectes glauca*, Cope) (8·39 per cent. of the fatty acids). No evidence was obtained of the presence of two highly unsaturated acids, $C_{20}H_{32}O_2$ and $C_{24}H_{40}O_2$, stated by Bull (Chem. Zeit., 1899, 906) to be present in herring oil.—A. S.

Soaps; Revised classification of ——, in Bulgaria. Bd. of Trade J., Aug. 2, 1906. [T.R.]

A circular has been issued by the Minister of Finance containing modified instructions to Bulgarian Customs officials with regard to the tariff classification of imported soaps.

The following are declared to be dutiable under No. 170 of the tariff as "toilet soaps, &c." at the (conventional) rate of 70 frs. per 100 kilos. (£1 8*s.* 5*d.* per cwt.):—

(*a*) All scented, medicinal, and cosmetic soaps, without regard to their size, shape, or packing.

(*b*) All unscented soaps of the usual shapes and packed in the ordinary manner, where it is proved by analysis that the bulk of the stock of which they are made is refined, as in the case of toilet soaps, *i.e.*, that it contains no other admixture than refined salts of sodium or of sodium and potassium.

(*c*) All coloured soaps, scented or not, having the shapes of toilet soaps.

The following will be dutiable under No. 134 as "soaps for washing and other ordinary use" at the (conventional) rate of 12 frs. per 100 kilos. (4*s.* 10½*d.* per cwt.):—

(*a*) All soaps with regard to which it is established by analysis that they are made of an unrefined stock, *i.e.*, similar to that of which common soaps are generally made, even though such soaps be shaped and packed like toilet soaps.

(*b*) Unscented soaps, prepared by means of a refined or coloured stock or not, if imported in the shape of large cubes (*pains*) or bars, and destined for laundry purposes; and

(*c*) All other soaps made of an unrefined stock and destined exclusively for laundry purposes.

In their reports on the results of the analyses made, the officials are to state specifically that "the stock is refined" or "the stock is unrefined," in order to intimate that in the first case the soap is dutiable under No. 170, and in the second case under No. 134.

Soap for wool-washing in Natal. Bd. of Trade J., Aug. 2, 1906. [T.R.]

The "Natal Government Gazette," for June 29 last, contains a proclamation notifying that a rebate of the whole of the Customs duties will be allowed upon soap and other substances imported for, and used exclusively in connection with the industry of wool-washing in the Colony.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*Continued from page* 769.)

(*A.*)—PIGMENTS, PAINTS.

Ultramarine; Contributions to the study of ——. C. Chabrié and F. Levallois. Compt. rend., 1906, **142**, 222—224.

When ultramarine is heated with silver nitrate solution in a sealed tube at 140° C. for many hours, much silver nitrite is formed besides the products noticed by former observers.

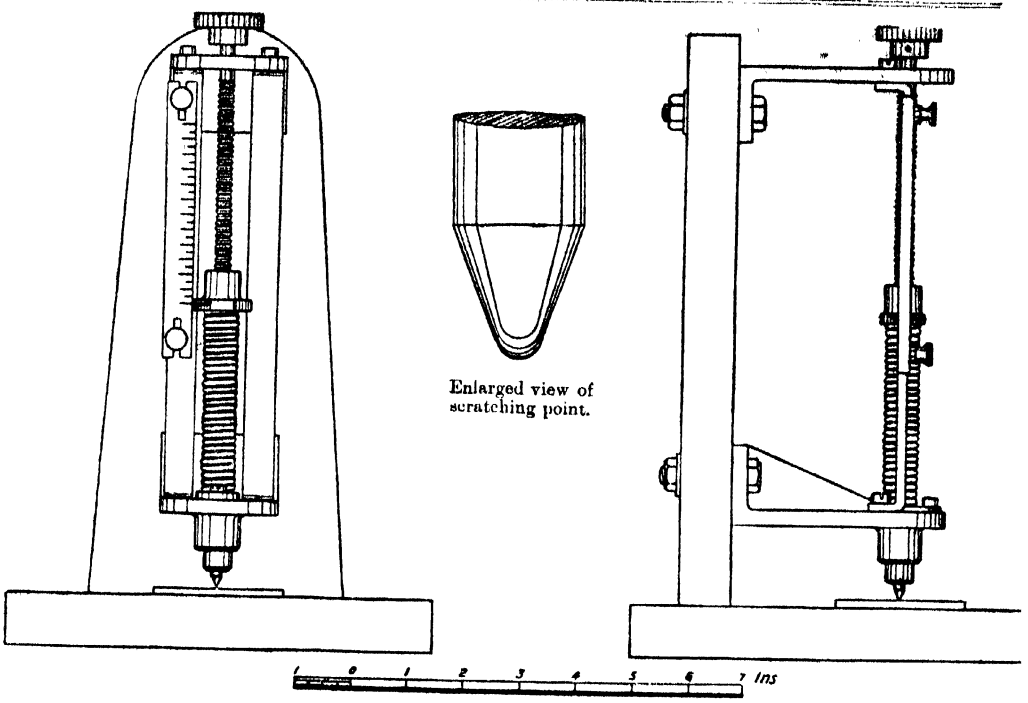
Sodium is not entirely replaced by silver in silver ultramarine, and therefore the formula based on this assumption is open to question. The ethyl, phenyl, and benzyl derivatives of ultramarine, on treatment with hydrochloric acid, do not give off sulphuretted hydrogen, as does the original blue, being unattacked by that acid in the cold. They lose their sulphide character on heating in the air, whereas ordinary ultramarine is little altered by this treatment. The ordinary blue is desulphurised by heating with mercuric oxide. By heating with water at 200°—300° C. for 100 hours, ultramarine is completely decolorised, sodium sulphide going into solution, and the residue containing no sulphur.—F. Sodn.

(*B.*)—RESINS, VARNISHES.

Turpentine oil; Swedish ——. J. Kondakow and J. Schindelmeiser. Chem.-Zeit., 1906, **30**, 722—723.

Oil of turpentine is termed pine-needle oil and pine-wood oil, according as it is distilled from pine needles or the thicker parts (roots) of the pine tree.

These oils, whether of Russian, Swedish, or French origin, are dextro-rotatory (this J., 1906, 487), and contain *d*-pinene, *d*-sylvestrene, and probably bornyl acetate. By repeated fractionation of a specimen of Swedish turpentine oil, and subsequent treatment with hydrochloric acid gas, the authors obtained a residue which was optically inactive and consisted of *p*-cymene. This is probably the first time that the existence of this substance in turpentine oil has been proved.—C. E. F.



Gum elemi. A. Vesterberg. Ber., 1906, **39**, 2467—2472.

The crystallisable part of Manila gum elemi contains two isomeric monohydric alcohols (this J., 1891, 56): these are α- and β-amyrin, having the formula, $C_{30}H_{49}OH$, and are dextro-rotatory. This gum elemi contains also breïn, which is separated from amyrin by crystallisation from benzene. Breïn is a dihydric alcohol and has probably the formula $C_{30}H_{48}(OH)_2$. It is dextro-rotatory; measurements on an alcoholic solution gave $[\alpha]_D = 65·5°$.

Breïn and breïn acetate, when dissolved in acetic anhydride and treated with concentrated sulphuric acid, give a yellow solution which on warming becomes dark brown. Amyrin tested in this way gives a reddish-violet coloration.—C. E. F.

Varnishes; A new method of testing the hardness and elasticity of ——. A. P. Laurie and F. G. Baily. J. Roy. Scott. Soc. Arts., 1906, **17**, 101—110.

The method devised by the authors consists in determining the degree of pressure required to scratch a film of the given varnish by means of a hard point. The apparatus they have constructed for the purpose (see Fig.) has a central rod moving easily in openings in the two horizontal supports. The upper part of this rod has a screw thread on which is a running nut, prevented from turning, by guides which project into its wings, but made to travel up and down by turning the milled head at the top of the rod. To the lower part of the nut is attached one end of a helical steel spring, the other end of which is

fixed to the lower bracket. A blunt point of hard steel with a radius of 1 mm. is fixed to the lower end of the rod, and can be raised or lowered by screwing the nut up or down so as to compress or slacken the spring. The plate with the film of varnish is placed beneath this, and the point brought exactly to the same height, which is taken as zero. Any arbitrary scale can be used, and should be attached to one of the guides, whilst a fiducial mark is made on the wing of the nut. In the authors' apparatus, the spring gave a maximum pressure of 1200 grms. (which was required by few of the best varnishes), and the scale indicated fractions of a kilo., 1 representing 0·1 kilo., 2 representing 0·2 kilo., and so on. The film was prepared by heating the thoroughly cleansed and polished plate, and the varnish, together in a hot water oven, then pouring the varnish on to the centre of the glass, distributing it with the finger, warming the plate to make the layer level and uniform, and finally leaving it to dry in a cupboard with levelled glass shelves. In testing the varnished surface, the point of the instrument is raised to the zero position, and the plate drawn slowly and smoothly across it, the pressure being meanwhile gradually increased by turning the milled head, until a white scratch becomes visible. In many cases, grooving appears long before the scratch, but so long as the transparency of the varnish is unaffected, this can be neglected. It is, in fact, rather an indication of toughness. The results thus obtained by different observers usually agree within 5 per cent. The thickness of the film has but little influence unless it be excessively thin or thick. In experiments with varnishes prepared by the authors, it was found that mastic varnish, which was taken as typical of a spirit varnish, broke down at a pressure of 1, and the fracture examined under the microscope had a characteristic conchoidal appearance. Oil varnishes prepared from rosin varied in hardness from 1 to 3, according to the proportion of the oil; whilst varnishes prepared from copal, animi, manila, and kauri resins with oil and turpentine, required a pressure of 9 to 12.

Rosin varnish hardens rapidly and the process is complete in a short time. On the other hand, the hard church oak varnishes dried very slowly, in spite of the process being accelerated by heating them to 70°—80° F. for a fortnight, after eight months' drying. In order to determine the influence of the atmosphere and frost upon the varnishes, plates were exposed to the air for three months. It was found that the amber varnish and an inferior copal had deteriorated after a fortnight and had quite disappeared in three months. The oak varnishes showed cracks, and one of them had peeled slightly. The other trade varnishes were apparently sound and transparent, but their hardness had fallen to 1 or 2, and the scratch produced had a splintered appearance. It is pointed out, however, that these varnishes would probably have lasted better on an absorbent surface. The authors conclude that the test is capable of detecting deterioration in a varnish before it becomes manifest to the eye.—C. A. M.

Rosin size; Detection and determination of ——. H. Rebs. XXIII., page 830.

Turpentine and resin industry of United States. Foreign Office Misc. Series, No. 647. [T.R.]

The British Commercial Agent, Mr. Bell, has, acting under instructions from the Foreign Office, made an investigation of the turpentine and resin ("Naval Stores") industry of the United States, and the following is a summary of his report:—

The following figures, taken from the United States census returns, show the progress of the industry since 1850:—

Year.	Number of Establishments.	Value of Products.
1850	856	$2,855,659
1860	625	6,468,367
1870	227	3,585,225
1880	508	5,876,983
1890	670	8,077,379
1900	1,503	20,344,888

Resin is obtained chiefly from the long leaf pine, of which there was formerly an unbroken forest extending from Southern Virginia through the South Atlantic and Gulf States to Eastern Texas. More than one-half of the

original forest, however, has been exhausted and there has been little or no renewal.

For a number of years the seat of the naval stores industry continued near the forests of North Carolina. It was transferred to South Carolina at a later period, and within recent years the districts have been very much extended, and now the centre is in Florida and reaches into Alabama, Mississippi, and Louisiana.

Under the present methods of cutting the trees, it is merely a question of a comparatively short time before the supply will be exhausted. The best quality of crude turpentine from the long leaf pine is obtained during the first year the tree is worked. Each succeeding year the colour becomes deeper and the resin is poorer in volatile oil. After the fourth year the turpentine orchard is generally abandoned. It is only in North Carolina that the smaller landowners work their trees for 10 or more successive seasons, protect the trees against fire, and, after giving them a rest for a series of years, apply new boxes on spaces left between the old chips—"reboxing."

The present system of gathering turpentine in the United States cannot be otherwise than wasteful. It has been proved that the cutting of the box does not assist the flow of turpentine, but, on the contrary, it diminishes the flow. The cut weakens the tree, leaving it more subject to being blown down, and opens the trunk to disease.

With a view to avoid if possible this waste the United States Department of Agriculture undertook in 1901 a series of experiments. Many suggestions were made and tested, but only one was found to be of value, and it has already been put in operation. The new method is styled the cup and gutter system.

The value exported from the United States in 1904 and 1905 is shown as follows:—

	1904.		1905.
Resin	$6,621,870	..	$7,069,084
Tar	44,944	..	60,520
Turpentine and pitch	32,253	..	74,938
Spirits of turpentine	9,446,155	..	8,902,101
Total	$16,145,224	..	$16,106,643

Of the spirits of turpentine exported in 1905, 43·1 per cent. went to the United Kingdom, 14·5 per cent. to Belgium, and 14·1 per cent. to Germany. Of the remaining naval stores 24·3 per cent. went to the United Kingdom, and 28·1 per cent. went to Germany.

English Patents.

Waterproofing composition, applicable also as a vehicle for pigments. T. L. Leishman, Edinburgh. Eng. Pat. 4533, Feb. 24, 1906.

The following compositions are claimed: (*a*), a vehicle for the preparation of waterproof paints, and (*b*), a waterproof coating for fabrics.

	(*a*)		(*b*)
Linseed or other drying oil	70	..	80
Oxidised rosin	15	..	5
Casein	5	..	5
Lime water (or equivalent)	10	..	10
Algin solution (1 in 10)	11	..	11

Linoleum for writing or drawing purposes; Process for the manufacture of mono-coloured ——. A. Sommer, Siegen, Germany. Eng. Pat. 8884, April 12, 1906. Under Int. Conv., May 19, 1905.

Suitable quantities of powdered glass, powdered pumice-stone, and the constituents of wall or "black" board varnish are added to the linoleum composition during the mixing process. The mass is then rolled, pressed, and dried in the usual manner. It is stated that the resulting linoleum has a rough surface, which remains unaltered after long use, and is suitable for writing and drawing purposes.—A. S.

(*C.*)—INDIA-RUBBER, &c.

India rubber; Vulcanisation of —— *in presence of litharge.* R. Ditmar. Gummi-Zeit., 1906, **20**, 1077—1078.

A mixture of Peruvian, Manaos scrap, and "thimbles" was vulcanised with 5 per cent. of sulphur, and increasing proportions of litharge; one series of test-pieces was cured in the autoclave for 45 minutes, at 145° C., and another similar series in the hot-air oven for two hours at 130° C. The elasticity of the products showed no regular variation with the amount of litharge added, and was throughout greater in the latter series than in the former. The strength increased with the proportion of litharge, but reached a maximum, in the steam cure series, at 35—40 per cent. The best results, on the whole, were obtained with 35 per cent. of litharge in the steam cure, and 30 per cent. in the dry cure. Blank specimens without litharge were found to be well vulcanised in the autoclave, but scarcely at all in the air oven.—W. A. C.

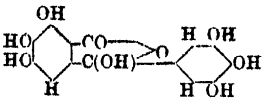
India rubber; Chalk in vulcanised ——. E. Herbst. Gummi-Zeit., 1906, **20**, 998—999.

A statement of R. Ditmar (this J., 1906, 326) has evoked a controversy on the influence of chalk in rubber, which turns mainly on the meaning of the term "colloidal combination." However this may be, the author shows by experiment that chalk, when present in vulcanised rubber, is certainly attacked and dissolved out by dilute acids.—W. A. C.

English Patent.

Fabrics; Manufacture of ——, *by covering leather, rubber, and other materials with cork.* Soc. Anon. du Grimson, Charenton, France. Eng. Pat. 26,599, Dec. 20, 1905. Under Int. Conv., July 5, 1905.

Cork, previously cut into thin sheets and "molecularly transformed" (see Eng. Pat. 14,839 of 1904; this J., 1905, 887), is "demineralised," soaked in a solution of pure Para rubber in benzine, and dried. The cork thus treated is fixed on the india-rubber or other fabric to be coated by means of a cement or an adhesive with a rubber base, and the coated fabric is vulcanised. Claim is made for the manufacture of protecting bands for pneumatic tyres by this process.—A. S.



XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 770.)

Tannin; Constitutional formula of ——. J. Dekker. Ber., 1906, **39**, 2497—2502.

The author shows that Schiff's digallic acid formula for tannin is not in accord with its properties. Tannin is dextro-rotatory (see Walden, this J., 1898, 190). A sample of the purest tannin (*Tannigenum levissimum purissimum*) had $[\alpha]_D = 65°$; on boiling a 10 per cent. aqueous solution with one-quarter of its volume of 10 per cent. sulphuric acid under a reflux condenser, the rotation fell to $[\alpha]_D = 22°$ after 1 hour, $[\alpha]_D = 7°$ after 2 hours, and $[\alpha]_D = 6°$ after 6 hours, whilst after the same periods the percentages of unaltered tannin were 48·7, 26·6, and 26 respectively. The constitutional formula of tannin should afford an explanation of the following facts:—(1) The almost complete conversion into gallic acid by hydrolysis. (2) The production of diphenylmethane by distillation with zinc dust (Nierenstein). (3) The production of a hexamethyl derivative of tannin. The compound prepared by Herzig and Tscherne from tannin by the action of diazomethane must be regarded as a hexamethyl derivative, both on account of its analytical figures, and the production of trimethylgallic acid from it by the action of alcoholic potash. (4) The electric conductivity of tannin, which is so low that the compound can scarcely be regarded as an acid. (5) The properties of the benzoyl derivative (Böttinger), which point to the absence of a carboxyl group and the probable presence of a carbonyl group. Further, the acetyl derivative of tannin is shown to give figures which agree best with those of a hexa-acetyl derivative. The formula which affords

the best explanation of these facts, and also the formation of rufigallic acid (hexahydroxyanthraquinone) by the action of concentrated sulphuric acid on tannin, is the following:—

—A. S.

Jellies; Influence of foreign substances on diffusion in ——. H. Bechhold and J. Ziegler. Z. physik. Chem., 1906, **56**, 105—121.

THE authors made a series of experiments to ascertain the effect of the addition of certain substances (electrolytes and non-electrolytes) on the diffusion of other substances (colouring matters and electrolytes) in gelatin and agar jellies. The electrolytes used were sodium chloride, sodium iodide, and sodium sulphate; the non-electrolytes were dextrose, glycerol, alcohol, and urea; and the colouring matters were Methylene Blue, Azolitmin from litmus, and the red juice of the beet. The influence of the added substances on the melting points of the jellies was also determined, but there appeared to be no relation between the effect on diffusion and on the melting point. The diffusion of the red beet juice in gelatin jelly is only slightly affected by the addition of sodium chloride or sodium iodide to the gelatin; any influence is exerted in the direction of favouring diffusion. Addition of sodium sulphate favours diffusion. None of the three substances mentioned has any influence on the permeability of the gelatin itself, the colouring matter diffusing just as far into a 20 per cent. jelly as into a 5 per cent. jelly. Sodium chloride and sodium iodide have no effect on the diffusion of beet juice in agar jellies, nor on the permeability of agar. Sodium sulphate retards diffusion, but has no influence on the permeability of the agar. Dextrose, glycerol, and alcohol retard the diffusion of beet juice in both gelatin and agar jellies; they also increase the permeability of gelatin, but have no effect on that of agar. Urea accelerates slightly the diffusion of beet juice in the jellies, but has practically no effect on the permeability of the colloids. Dextrose and glycerol accelerate the diffusion of Methylene Blue in gelatin jellies; alcohol and urea also accelerate diffusion in 5 per cent. gelatin jellies, but have little effect in the case of 20 per cent. jellies. The permeability of gelatin for Methylene Blue is increased by dextrose, hardly affected by glycerol, and diminished by alcohol and urea, especially by the latter. Gelatin in the form of a 5 per cent. jelly is impermeable to Azolitmin, but becomes permeable even up to a concentration of 20 per cent., if urea be added to it. Dextrose, glycerol, and alcohol retard the diffusion of sodium chloride and sodium sulphate in both gelatin and agar jellies, but increase the permeability of the colloids. Urea has a much smaller retarding influence on the diffusion, and at times even acts favourably.—A. S.

Eucalyptus; Recent chemical discoveries relating to the ——. H. G. Smith. XX., page 826.

Egg-yolk; Proposal for an official method for the commercial analysis of ——. Report of Turin Congress Commission. XXIII., page 829.

UNITED STATES PATENT.

Tanning; Process of ——. J. L. Martin, Terrell, Tex. U.S. Pat. 825,852, July 10, 1906.

THE hide is tanned with a mixture of 10 galls. of "broomweed ooze," 4 lb. of gum-gambier, 1 lb. of powdered alum, 2 lb. of common salt, and 3 lb. of persimmon bark.—A. S.

FRENCH PATENT.

Leather and leather articles; Process for strengthening, stiffening, and waterproofing ——. E. Laurent. Fr. Pat. 363,045, Feb. 7, 1906. Under Int. Conv., March 2, [illegible], and Feb. 8, 1906.

[illegible] process consists in immersing the leather in a bath of molten paraffin at a temperature not exceeding 70° C. The soles of boots may be dipped in the bath, and in the case of leather for wheel-tyres, the strips are mounted on moulds so that only the tread of the tyre is immersed in the bath, leaving the edges of the strip supple.—W. P. S.

XV.—MANURES, &c.

(*Continued from page* 770.)

Vinasse and molasses; Treatment of ——, for recovery of nitrogenous matter after removal of potash. Vasseux. XVII., page 823.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 771.)

Beetroot; Process for complete extraction of sugar, without formation of by-products, from ——. E. Lallemant. Bull. Assoc. Chim. Sucr. et Dist., 1906, **23**, 1428—1434.

THE beetroot, in the form of cossettes, is rapidly dried at a medium temperature in Lafeuille's drying apparatus; no loss of sugar occurs in this operation if the latter is properly conducted. The dried cossettes are then ground as finely as possible, and heated with 90 per cent. alcohol (150 litres per 100 kilos. of dry cossettes) at 75° C. until the latter is saturated. The alcoholic solution is run into a cooling apparatus and, when cold, is seeded with a small quantity of finely ground sugar. The sugar readily separates, impurities being left in the solution. The cossettes may be treated with a second quantity of hot alcohol while the first solution is cooling. After separation of the sugar, the mother liquor from the first solution is used for another extraction of the cossettes, the second solution being run into the refrigerator, and being cooled in its passage to the latter by the cold mother liquor of the first solution. A saving of fuel is thus effected. The above cycle is repeated until all the sugar is dissolved out of the cossettes (10 to 12 operations according to the sugar content of the beetroot). The mother liquors may be used to dissolve the sugar from five more batches of cossettes, and hence the amount of sugar remaining dissolved in the final mother liquor is comparatively very small (scarcely 0·15 per cent. of the beetroot). The alcohol is recovered from the mother liquors and exhausted cossettes by distillation, the last traces being removed from the latter by a current of hot air. The dried, exhausted cossettes form a very good cattle food. The sugar which is deposited in the refrigerating apparatus, and which retains a small quantity of alcohol, is at once dissolved to a syrup in slightly alkaline water. The syrup is then boiled, the alcohol being collected separately and returned to the general reservoir of the factory. Owing to the purity of the syrup, the subsequent refining is simpler and more economical than by other processes. The amount of alcohol required in the above process is comparatively small (131·25 hectolitres for 21 tons of beetroot) and only a small quantity is required to make up for loss due to leakage, &c.—L. E.

Diffusion juice; Acidity of ——. A. Grosjean. Bull. Assoc. Chim. Sucr. et Dist., 1906, **23**, 1418—1420.

FROM the estimations of acidity of various samples of diffusion juice by L. Herme's method the author draws the following conclusions:—In diffusion juice of acidity corresponding to not more than 0·120 grm. of oxalic acid ($C_2H_2O_4.2H_2O$) per 100 c.c., the apparent purity varies very slightly, and the amount of glucose present is small. In juice of higher acidity there is a decided decrease in the purity and a considerable increase of reducing sugars. In all cases the degree of purity and the amount of reducing sugars in the juice are closely connected with the acidity of the latter. The author also quotes experiments which show that the juice deteriorates much more rapidly when kept in the collecting back than it does when it remains in the diffusion battery for the same length of time.—L. E.

Polarisation of sugar solutions; New researches on the total effect of clarification with basic lead acetate on ——. L. Pellet. Bull. Soc. Chim. Sucr. Dist., 1906, 23, 1466—1471.

In clarifying sugar solutions with basic lead acetate, two sources of error are introduced:—(1) Owing to the volume occupied by the precipitate, the true concentration of the sugar solution is greater than the apparent concentration, the polarisation reading being thereby increased. (2) The precipitate retains a quantity of the sugar mechanically, the polarisation reading being thereby reduced. To determine how far these errors compensate each other, the author has made the following experiments:

A measured quantity of molasses was placed in a graduated flask, clarified with basic lead acetate, mixed, made up to volume at a known temperature, filtered, and polarised. A similar quantity of the same sample was clarified in a small flask with exactly the same amount of basic lead acetate as before, mixed, filtered rapidly through a small filter, and the filtrate collected in the same graduated flask as was used in the first experiment. The precipitate was then washed perfectly free from sugar, the washings added to the filtrate, the whole made up to volume at the same temperature, passed through a filter of the same kind, and polarised in the same tube and at the same temperature as in the first experiment.

In the first case the reading was affected by the errors above mentioned; in the second, these errors were eliminated. Molasses from various sources were examined. The results show that, on the average, the readings obtained after removing and washing the precipitate are very slightly higher than when the clarified solution is read directly after filtration. The differences, however, are within the limits of experimental error, and, practically, there is no necessity to make any correction on account of clarification with basic lead acetate. The author also cites an experiment on Scheibler's method. Two quantities of 50 c.c. of molasses were each clarified with 22 c.c. of lead solution, and made up to 100 and 200 c.c. respectively. The first polarised 50·395, and the second 50·420 (mean of 20 readings). Owing to greater concentration, more sugar was retained by the precipitate in the first case than in the second, but the volume of the precipitate also bore a greater proportion to the volume of the solution; hence the readings were almost identical, the latter being, contrary to Scheibler's theory, slightly higher.—L. E.

Maple products; Determination of the lead [malic acid] value of ——. A. P. Sy. XXIII., page 830.

Vinasse and molasses; Treatment of ——, *for recovery of nitrogenous matter after removal of potash.* Vasseux. XVII., next column.

Sugar duties in Great Britain in 1905–06. Ann. Rep. of Comm. of Customs. Sugar Customs Rep., 1906. [T.R.]

The net revenue from the sugar duties reached a total of £6,177,953, or practically the same as in the previous year. Included in this amount is £154,441 duty received on account of sugared goods and saccharin, and £162,622 for glucose, both these amounts being slightly better than the previous year. Of molasses 1,033,793 cwt. was delivered on drawback or free of duty to the British distiller, thus enabling him to manufacture cheap spirit, compared with 932,985 cwt. in 1904–05. Most of it is of foreign and colonial make.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 773.)

Barley cultivation experiments of the Verein Versuchs- und Lehranstalt für Brauerei; Report on ——. C. v. Eckenbrecher. Wochensch. f. Brau., 1906, 23, 365—368, 377—382.

This report deals with Original Hanna barley, Heines Hanna barley, "Hannchen" barley, Primus barley, and Svanhals barley grown in various soils during the year 1905. The season was a wet one, and consequently the grain was only of medium quality. Moreover, in the majority of the experimental fields the weather conditions during harvest were very unfavourable. The "Hannchen" barley gave the most abundant yield and best type of grain for brewing purposes, particularly when grown in light soil, and in many cases also when grown in better barley soil. The yield of straw was second only to that of Heines Hanna barley. The "Hannchen" barley showed the greatest weight per hectolitre, the least weight per 1000 corns, and the lowest percentage of albumin (11·77) of the above-mentioned kinds. The quality of the grain also was the best. The two Hanna barleys stood next to the "Hannchen" barley. Original Hanna barley gave a better yield of grain than Heines Hanna barley; the latter, however, was of better quality. Their albumin contents were 12·26 and 12·16 per cent. respectively.

The two Imperial barleys, Primus and Svanhals, in all cases, especially when grown in light soil, gave the smallest yields, and were decidedly poorer in quality than the above-named varieties. Their albumin contents were 12·33 and 12·66 per cent. respectively.—L. E.

Wines; The "graisse" disease [ropiness] of ——. E. Kayser and E. Manceau. Compt. rend., 1906, 143, 247—248.

The results of experiments with the ferment described previously (this J., 1906, 386) are given, particular attention being paid to the degree to which various sugars are attacked by the ferment and to the products formed. Portions of a white wine of the Champagne district, after receiving the addition of different sugars, were inoculated with the ferment, and kept in closed bottles for a month. The following figures represent grms. per litre:—

	Original sugar.	Sugar remaining.	Sugar destroyed
Wine, no added sugar	1·60 (as lævulose)	1·31	0·29
Wine, + dextrose	34·09	29·18	8·91
Wine, + saccharose	33·57	15·33	18·24
Wine, + lævulose	22·21	1·59	20·62

The organism, consequently, thrives best in a medium containing lævulose. The products formed vary according to the sugar which has been attacked; lævulose gives mannitol, lactic, acetic, and traces of higher acids; dextrose yields lactic and volatile acids; and saccharose gives the products of lævulose and dextrose.—W. P. S.

Vinasse and molasses; Treatment of ——, *for recovery of nitrogenous matter after removal of potash.* Vasseux. Bull. Assoc. Chim. Sucr. et Dist., 1906, 23, 1381—1382.

The nitrogenous matter contained in molasses is more valuable than the potassium salts contained in the latter; it is generally lost, however, by incineration during the process of working up the saline matter. The author proposes the following method for its recovery:—The vinasse, after concentration to a suitable degree, is treated with the requisite quantity of sulphuric acid. Nearly the whole of the potash is converted into sulphate which crystallises out. The mother liquors are evaporated to dryness in special apparatus. The nitrogenous organic residue contains 5—7 per cent. of nitrogen and 6—7 per cent. of potash.—L. E.

Malt extracts; Examination of commercial ——. E. F. Harrison and D. Gair. XXIII., page 830.

Yeast; Acclimatisation of —— *to saccharine mineral nutrient media. "Bios" question.* H. H. Pringsheim. Centr. Bakt., Abth. 2, 1906, 16, 111—119. Woch. f. Brau., 1906, 23, 401.

Wildiers observed that although a single cell of yeast is sufficient to start a culture in media containing organic nutrients, it is necessary to sow a large number of cells in order to obtain cultures in media containing nothing but

sugar and mineral salts. The difference is essentially one which concerns the nitrogen, phosphorus, and sulphur. The author explains that if these elements are already present in the form of albuminoid derivatives, *e.g.*, peptones, a very much smaller expenditure of energy is necessary on the part of the yeast to effect their reconversion into albumin than if they are present as ammonium and other mineral salts. Although yeast can accommodate itself to the greater strain involved by the synthesis of its albumin from mineral nutrients, several of the cells succumb in the process. The organic products of these cells assist the survivors in the same way as an addition of a yeast decoction. The minimum number of cells which will grow in a mineral medium is smaller in the case of yeast taken from a wort-culture rich in nitrogen than in the case of pressed yeast which is generally poor in nitrogen. It is quite unnecessary to assume, as Wildiers does, the existence of a specific principle ["bios"] to explain these observations.—J. F. B.

Spirit duties in Great Britain in 1905–06. Ann. Rep. of Comm. of Customs. [T.R.]

The net receipts from foreign spirit show a decrease of £97,839, or 2·56 per cent., as compared with 1904–05, following on a decrease of £635,936, or 14·3 per cent., in the preceding year. This is mainly due to a falling-off in the importation of foreign plain spirit, both for potable and for industrial purposes, the amount imported from Germany being 186,934 galls., against 338,836 galls. in 1904–05, while there were no importations of foreign spirit for methylating purposes last year, the decrease having been continuous since 1902–03, in which year 1,196,167 galls. were imported for methylating. During the past five years wide variations have occurred both in the quantities imported and the average values of the imports of spirit from Germany, which variations are mainly governed by the quantity of potatoes available in Eastern Europe for conversion into spirit. Low prices ruled from 1901 to 1903, the imports in those years being 3,089,909 galls. and 1,808,769 galls. respectively; consequently spirits of this kind displaced home-made spirits to a great extent during those years. Now the position is reversed, as, owing to the advanced prices ruling in German spirit during the past two years, the British distiller has been enabled to hold his own at home, and hence the trade with Germany is almost at a standstill. The quantity of foreign spirits retained for home consumption again fell last year to 750,865 proof galls., yielding £477,290, or a decrease of 8·06 per cent. In the case of perfumed spirits there is little change—37,217 galls., yielding £33,900, having been imported, compared with 38,163 galls., yielding £34,707, in 1904–05.

Spirit; Duty free ——, *in U.S.A.* Oil, Paint, and Drug Rep., Aug. 6, 1906. [T.R.]

The preliminary annual report of the Commissioner of Internal Revenue for the fiscal year 1906 is unusually interesting, owing to the bearing it has upon the newly adopted free alcohol policy of the Government.

The receipts from all sources of internal revenue for the fiscal year 1906 were $249,102,738, as compared with $234,187,976 for 1905, an increase of 6 per cent. The increase in 1906 over 1904 was only 0·5 per cent. The cost of collecting the revenue in 1906 was $4,720,768, or about 2 per cent. The principal items of revenue included $143,394,053 from distilled spirits, $55,041,858 from fermented liquors, and $48,422,997 from tobacco. While the largest relative increase is noted in fermented liquors, it is suggestive that the increase in the tax on distilled spirits was no less than $7,435,542 in 1906 over 1905, while in 1905 the increase over 1904 was less than $150,000.

The very large increase in the tax paid on distilled spirits in 1906 is highly encouraging to the administration, and especially to the officials of the Internal Revenue Bureau, who are looking forward with considerable anxiety to the effect upon the revenues of the new law granting free denatured alcohol for industrial purposes. The most authoritative estimates thus far made with regard to the effect on the revenues of the free alcohol statute predicts a loss of $200,000 to $600,000. This is a negligible sum in view of the magnitude of the revenue from this source, but even the preposterous figures submitted by the opponents of the free alcohol law, at the recent session of Congress, indicating a loss of $5,000,000 per annum, have no terrors for the Treasury officials in view of the current increase in the spirit revenue. This is believed to be due not only to increased consumption, but especially to better administrative methods, which have reduced illicit distillation to a minimum and made it practicable to collect the tax on nearly all the spirits actually produced.

United States Patents.

Fermentable products from grain; Process of developing the ——. A. F. Kniesche, Syracuse, N.Y. U.S. Pat. 825,662, July 10, 1906.

This process consists in preparing a mash of corn-meal, cooking the same for a sufficient length of time at a temperature of about 212° F., cooling to 150° F., and then stirring in uncooked dry rye-meal; adding to this mash a mixture formed by macerating malt-meal in water at a temperature of 50°—80° F., until the water has extracted the diastase and other soluble parts of the malt; then allowing the whole mixture to rest from one to two hours at about 142° F. to convert the contained starch into fermentable sugar, and afterwards cooling the entire mixture to 75°—80° F.—T. H. P.

Soy; Process of brewing ——. T. Suzuki, Sunamura, Japan. U.S. Pat. 825,500, July 10, 1906.

This improved process consists in initially mixing approximately 5·1 bushels of barley with 5·13 bushels of soy beans, adding about 2·05—3·6 "bushels" of salt dissolved in 63·52 imperial galls. of boiling water, slowly and continuously stirring under a substantially constant heat until matured, then adding further saline solution, and continuing the stirring for several days.—T. H. P.

Wood-alcohol; Process of making ——. H. O. Chute, Cleveland, Ohio. U.S. Pat. 824,906, July 3, 1906.

This process consists in distilling from crude pyroligneous acid a concentrated distillate of between 10 and 25 per cent. alcohol content and of acid nature, in which oily impurities are insoluble; allowing the distillate to stand to permit the impurities to separate; decanting off the clear liquid, and adding to it an excess of alkali; decanting from the resinous deposit formed, and refractionating the decanted liquid to form a strong alcohol which is above 80 per cent. strength and perfectly miscible with water.—T. H. P.

Alcoholic spirits; Process for producing ——. G. W. Palmer, Seattle, Wash. U.S. Pat. 825,342, July 10, 1906.

Claims are made for a sour-mash process of producing spirits without the use of grain or malt, consisting in inducing rapid fermentation in a new or sweet mash composed of bran, sugar, and water by adding to it a retained portion of the old or sour mash composed of the same ingredients previously fermented and soured.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 775.)

(*A.*)—FOODS.

Mineral waters; Difference between the electrical resistances of natural and artificial ——. D. Negreano. Compt. rend., 1906, 143, 257—258.

The resistance of a natural mineral water is practically constant for the water from any particular spring, whilst waters prepared artificially in imitation of the natural spring waters have quite different resistances from the

latter. For instance, a sample of Vichy water had a resistance of 140 ohms at 18° C., and similar water, prepared artificially, a resistance of 112 ohms. Natural Evian water showed a resistance of 1280 ohms; similar artificial water had a resistance of 1120 ohms. The resistance of a natural mineral water diminishes with the temperature. For moderate ranges of temperature, the resistance at a temperature of $t°$ may be calculated to that at 18° C. by the formula: $R_t = R_{18}[1-\alpha(t-18)]$, where α is the coefficient of variation and is approximately 0·02.—W. Grain; Process of conditioning ——. H. J. Caldwell and J. R. Barr, Earl Park, Ind. U.S. Pat. 825,378, July 10, 1906.

IN this process, the superficially-moistened grain is subjected to the action of cooled bleaching chemical fumes, such as sulphurous fumes, either by themselves, or diluted with several times their own volume of air.—T. H. P.

(C.)—DISINFECTANTS.

FRENCH PATENTS.

Barium sulphide; Application of —— in agriculture [as insecticide]. C. P. Chalap. Fr. Pat. 362,967, Feb. 3, 1906.

BARIUM sulphide, and especially the crude sulphide obtained by the reduction in a furnace of barium sulphate, is finely powdered and dissolved in water, the solution being applied to vines attacked by oïdium. Or the sulphide may be mixed, for special purposes, with a copper salt; or with iron sulphate or zinc sulphate, for general use, to form a compost containing iron or zinc sulphide and barium sulphate, applicable in place of sodium sulphide or calcium sulphide against cryptogamic maladies. —E. S.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page 775.*)

Paper machine; Driving of the ——, and drying cylinders. C. Hofmann. Papier-Zeit., 1906, **31**, 2430.

THE essential part of the equipment of a high-speed paper machine consists of a very large number of drying cylinders. No satisfactory paper can be made if it has to be dried too rapidly, and in order to ensure gradual drying, every increment in the speed of the machine should be accompanied by a corresponding increase in the number of drying cylinders. The slower the drying, the less is the alteration in the length of the web, and if a sufficient number of moderately heated drying cylinders be provided, they can all be driven at the same speed, and the complicated mechanism for the regulation of the "draws" becomes unnecessary. The author describes a machine recently constructed in Germany which possesses 41 drying cylinders and eight separate felts and felt dryers. The machine is driven by a 300-h.p. engine, the exhaust steam from which is condensed in the drying cylinders. The speed of the machine can be varied between 59·5 and 160 metres per min., when working on "news," by simple regulation of the engine, whilst an alternative drive is provided for making cardboard, by which the speed can be varied between 25 and 66·5 metres per min.—J. F. B.

Cellulose acetate; Process of making ——. A. Corti, Dübendorf, Switzerland. U.S. Pat. 826,229, July 17, 1906.

CELLULOSE is heated with a mixture of acetic anhydride, acetic acid, and dimethyl sulphate, the proportion of acetic anhydride to acetic acid being in the ratio of 70 to 120.—J. F. B.

Cellulose; Product obtained from ——, and process of its manufacture. M. G. Olivier, Assignor to Soc. Franç. de la Viscose, Paris. U.S. Pat. 826,351. July 17, 1906.

CELLULOSE xanthate, whilst still in a soluble and uncoagulated condition, is ground to a smooth and plastic mass without the addition of water. The product is then compressed, and forced into suitable moulds, in which the xanthate is coagulated and decomposed. The regenerated cellulose is then washed, dried, and moulded.—J. F. B.

FRENCH PATENTS.

Cellulose compound; Process of making a non-nitrated, non-inflammable ——. C. Trocquenet. Fr. Pat. 362,989, Feb. 5, 1906.

THE compound consists of a mixture of cellulose, asbestos, and the organic matter contained in oyster shells. To obtain the cellulose, seaweed is successively treated with alkali and acid, and washed. The asbestos is ground to a paste with petroleum oil of sp. gr. 0·880, whilst the oyster shells are ground, treated with hydrochloric acid, and the insoluble residue boiled with water, then washed with water containing a weak alkali, and finally collected on a filter. From 55 to 65 parts of the cellulose, 2 to 12 parts of the oiled asbestos, and 20 to 45 parts of the oyster-shell substance are mixed together and treated with formaldehyde. After removing the excess of the latter, the mass is suitably coloured, pressed, and is then fit for use as a substitute for celluloid.—W. P. S.

Organic or inorganic compounds; Process for the reduction of ——. S. Kapff. Fr. Pat. 362,985, Feb. 3, 1906. VII., page 811.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page 777.*)

Meroquinine and the constitution of the cinchona alkaloids. W. Koenigs. Annalen, 1906, **347**, 143—232.

MEROQUININE, $C_9H_{15}O_2N$, can be obtained either by hydrolysing cinchene or quinene with aqueous phosphoric acid under pressure, or more conveniently by oxidising cinchonine with chromic and sulphuric acids. Meroquinine is easily soluble in water, sparingly so in alcohol, and forms colourless crystals, melting at 223—224° C.; it is dextro-rotatory, having $[\alpha]_D$ about 27·6°, and yields a characteristic hydrochloride, also gold and platinum double salts. The methyl and ethyl esters are oils giving crystalline hydrochlorides. Acetylmeroquinine crystallises in plates, melting at 100° C., whilst nitrosomeroquinine melts at 67° C.; the formation of these derivatives indicates the presence of an imino group in meroquinine. On oxidation with chromic acid, meroquinine is converted into cincholoiponic acid, whilst, when reduced, cincholoipone is formed. A saturated base β-ethyl-γ-methyl pyridine (β-collidine) is produced on heating with mercuric chloride and dilute hydrochloric acid. By the action of bromine water a hydrobromide of bromomeroquinine is formed, to which the author assigns a lactonic structure, and which, on boiling with water, is converted into oxymeroquinine, a colourless crystalline substance melting at 208°—210° C. These results make it possible to assign to meroquinine the formula

$$NH\begin{<}CH_2\cdot CH(.CH:CH_2)\\ CH_2\text{——————}CH_2\end{>}CH.CH_2.CO_2H.$$

The formation from cinchene takes place in accordance with the equation

$$\underset{\text{Cinchene.}}{C_9H_{20}N_2} + 2H_2O = \underset{\text{Lepidine.}}{CH_3C_9H_6N} + \underset{\text{Meroquinine.}}{C_9H_{15}O_2N}$$

The author discusses the work done both by Skraup and others and by himself on the cinchona alkaloids, and

the evidence available for establishing their constitution. Applying the formula above, established for meroquinone, he is able to propose structural formulæ for quinene, cinchonine, quinine, &c. The course of reasoning followed is briefly as follows:—

By fusing the cinchona alkaloids with potash the following compounds have been obtained:—Quinoline, lepidine (γ-methylquinoline), *p*-methoxyquinoline, β-ethylpyridine and β-ethyl-γ-methylpyridine. As oxidation products, the following have been identified:—γ-quinolinecarboxylic acid, α, β, γ-pyridinetricarboxylic acid and β,γ-pyridinedicarboxylic acid. The cinchona alkaloids are bitertiary bases; they yield monoacetyl derivatives, and therefore contain a hydroxyl group, quinine in addition containing methoxyl. They are unsaturated, adding 2 atoms of bromine or a molecule of the halogen hydrides, and therefore contain the vinyl group.

Quinine, $C_{20}H_{24}O_2N_2$, may thus so far be expanded to $C_9H_5(OCH_3)N.C_6H_{12}(OH)N.CH:CH_2$.

Cinchene and quinene differ from the corresponding alkaloids in being broken up on heating with concentrated hydrobromic acid into apocinchene $C_{19}H_{18}(OH)N$ and apochinene $C_{19}H_{19}O_2N$, which compounds have been proved to be *a*-phenylquinoline derivatives. On the other hand, on heating with phosphoric acid, quinene is converted into *p*-methoxylepidine and meroquinene. The constitution of this latter being established, it is possible to assign to cinchene ($C_{19}H_{20}N_2$) the formula

$$C_9H_6N.CH:\begin{array}{l}C.CH_2.CH<\begin{array}{l}CH(C_2H_3).CH_2\\CH_2\text{——}CH_2\end{array}>N\end{array}$$

which fully explains the above-mentioned decompositions. From this the structure of quinine may be deduced as

$$CH_3O.C_9H_5N.CH_2.C(OH)<\begin{array}{l}CH_2\text{——}CH\\[CH_2]_2\\N\text{——}CH_2\end{array}>CH.C_2H_3$$

The author draws attention to the great unstability of the quinine molecule and the large number of possible stereoisomerides. He forecasts the possibility of synthesising quinine either from β-ethyl-γ-methylpyridine or from *p*-methoxylepidine, but does not expect any possible technical future for this process any more than has attended the synthesis of atropine or cocaine.

—E. F. A.

Caffeine; New derivatives of ——. and the reactions of its glyoxaline nucleus. Brissemoret. Bull. Soc. Chim., 1906, **35**, 316—321.

When a hot solution of 10·5 grms. of caffeine and 7 grms. of salicylic acid in 1000 c.c. of water is suddenly cooled, the compound $C_8H_{10}O_2N_4.C_7H_6O_3$ separates out in the form of white needles, sparingly soluble in cold water, more soluble in warm water, and also in sodium acetate solution. The aqueous solution of this compound, which has an acid reaction to litmus, forms Tanret's double salt, $C_7H_5O_3Na.C_8H_{10}O_2N_4.H_2O$, when treated with the theoretical amount of alkali, and evaporated; this yields up its caffeine to chloroform. When the base is treated with 7·6 grms. of protocatechuic acid, under similar conditions, the analogous compound, $C_8H_{10}O_2N_4.C_7H_6O_4$, is obtained. If 9 grms. of gallic acid be employed in this manner, the resulting compound is $C_8H_{10}O_2N_4.C_7H_6O_5$, which forms grey, microscopic needles. These compounds are permanent in the air.

3·7-Dimethylxanthine forms similar compounds with these acids, but when neutralised with sodium bicarbonate the aqueous solutions of these liberate dimethylxanthine. Similarly, glyoxaline can be obtained, but on account of the solubility of the compounds in water, solutions in ether must be employed. Ethereal solutions of 1 grm. of glyoxaline and 2 grms. of salicylic acid give the compound $C_3H_4N_2.C_7H_6O_3$ in white needles insoluble in ether. 2-Methylglyoxaline gives similar compounds with salicylic and gallic acids. Benzoic acid reacts thus neither with xanthine nor glyoxaline bases.—J. O. B.

Iso-coniine and the synthesis of coniine. A. Ladenburg. Ber., 1906, **39**, 2486—2491.

As working with *d*-coniine purified through the bitartrate, the author concludes that iso-coniine is present in synthetic coniine. By heating *a*-picoline with aldehyde and water to 150° C., methylpicolylalkine,

$$NC_5H_4.CH_2.CH(OH).CH_3,$$

is produced, boiling between 116° and 120° C. at 13 mm. This substance was heated with hydrochloric acid to 185° C. and the product reduced with sodium and alcohol. The racemic coniine so obtained boils at 166°—168° C. The bitartrate of this base was crystallised from water, the solution being sown with a crystal of *d*-coniine bitartrate: the product obtained melted at 56° C. The iso-coniine obtained from this salt had $[\alpha]_D = 19·2°$. The rotation of the purest *d*-coniine is 15·6°. Iso-coniine boils at 167° C. corr.; sp. gr., 0·8445 at 20° C., and 0·8472 at 17° C. The hydrochloride melts at 221°—222° C., and the platinum double salt at 174° C. after drying. These results and the crystallographic properties of the salts agree with those of *d*-coniine. The sole difference between iso-coniine and *d*-coniine lies in the optical rotation. If *i*-coniine be heated with solid caustic potash to 240°—248° C. for several hours, a base with $[\alpha]_D = 17·1°$ is produced. Also if *i*-coniine be heated by itself to 290°—300° C. a base is produced boiling at 164°—166° C. and with $[\alpha]_D = 15·67°$, and which is practically pure *d*-coniine.—F. Shdn.

Eucalyptus; Recent chemical discoveries relating to the——. H. G. Smith. Brit. Pharm. Conf., Birmingham, 1906. Pharm. J., 1906, **77**, 101—102.

Kinos.—The best kino for pharmaceutical use, which does not gelatinise in tinctures, is the product of *Eucalyptus microcrys*, but it is not available in commercial quantities; the next best is that from *E. calophylla*, which can be obtained in quantity. The kino of *E. rostrata* is not so good, since it tends to gelatinise, and is not so astringent as the former kinds. There are two, if not three, tannins present in eucalyptus kinos. One of these, which gives a violet colour-reaction with ferric chloride, gelatinises in alcoholic solution. It is found in the kinos of the "iron barks," "stringy-barks," and "peppermint" eucalypts. The other tannin, which gives a green colour-reaction with ferric chloride, does not gelatinise.

Oxalic acid.—Since calcium oxalate occurs in considerable quantity in the bark of certain eucalypts, sometimes to the extent of 16 per cent., it might, when accompanied by tannin, be a cheap source of oxalic acid. In the case of *E. salubris* the considerable amount of tannin present, which is equal in tanning properties to that of "mallet-bark," is readily extracted. The residual bark should yield oxalic acid as a profitable by-product.—J. O. B.

Sodium amide and cyclic ketones. Derivatives and constitution of fenchone and camphenilone. F. W. Semmler. Ber., 1906, **39**, 2577—2582.

In dealing with fenchone and camphenilone, a reagent is required which will attack the CO-grouping and split the molecule in its neighbourhood. Where a dimethylated carbon atom is next to the CO-grouping, the action of sodium amide results in the breaking of the ring and the formation of the sodium amide of the corresponding acid

$$\begin{array}{l}C.C(CH_3)_2\\C.CO\end{array}\rightarrow\begin{array}{l}C.C(CH_3)_2\\H\end{array}+C.CO.NHNa.$$

Dihydrofencholenic acid amide (*b*), $C_{10}H_{19}ON$, is produced by boiling together molecular proportions of fenchone and sodium amide in benzene, and pouring the liquid into ice-water. The amide melts at 94° C., and boils at 160° C. at 11 mm. This amide is different from the isomeric dihydrofencholenic amide (*a*) obtained by Mahla (Ber., 1901, **34**, 3777) from fenchonimine and melting at 130·5° C. Dihydrofencholenic acid (*b*), $C_{10}H_{18}O_2$, boils at 140°—141° C. at 10 mm., has sp. gr., 0·9742 at 15° C., and sets to a solid at the ordinary temperature. The methyl and ethyl esters were prepared. On reducing the acid with sodium and alcohol, dihydrofencholenic alcohol (*b*), $C_{10}H_{20}O$, is produced. It boils at 100° C. at 11 mm.; sp. gr., 0·8869 at 22° C.; $n_D = 1·45662$. The corresponding aldehyde, $C_{10}H_{18}O$, boils between 90°—95° C. at 10 mm.; sp. gr., 0·886 at 20° C.; $n_D = 1·445$. The semicarbazone of this aldehyde melts at 144°—145° C. Camphenilone is attacked by sodium amide in the same way as fenchone.

with the formation of dihydrocamphoceenic amide (*b*), $C_9H_{17}ON$, melting at 168° C. The corresponding dihydrocamphoceenic acid (*b*), $C_9H_{16}O_2$, boils at 138°—139° C. at 12 mm.; sp. gr., 0·9815; $n_D = 1·45662$. The bearing of these results on the constitution of fenchone and camphenilone is then discussed.—F. Shdn.

Di-isoapiol, di-isoeugenol methyl ether, and di-asarone. T. Széki. Ber., 1906, **39**, 2422—2424.

An ethereal solution of isoapiol was saturated with hydrochloric acid gas; the ether was distilled off, and the residue heated in a sealed tube to 200° C. By crystallising the residue from alcohol, fine white crystals of di-isoapiol $C_{24}H_{28}O_8$, were obtained, melting at 97° C. The substance does not take up bromine. Di-isoeugenol methyl ether, $C_{22}H_{28}O_4$, was produced by a similar reaction from isoeugenol methyl ether. It forms snow-white silky needles, melting at 106° C., and does not take up bromine. Di-asarone, $C_{24}H_{32}O_8$, formed from asarone melts at 100° C., and does not form a bromine addition compound. Another compound, melting at 96° C. is formed with di-asarone. Its analysis agrees with that of symmetrical di-trimethoxyphenylethylene.—F. Shdn.

Benzoic acids; Differentiation of natural and synthetic ——. H. Cormimbœuf and L. Grosman. Ann. Chim. anal. appl., 1906, **11**, 243—244.

Synthetic benzoic acid from toluene invariably contains a distinct trace of chlorine, whereas the natural acid, sublimed from gum benzoin, is free from that element. —J. O. B.

Sulphoacetic acid. O. Stillich. J. prakt. Chem., 1906, **74**, 51—56. (See this J., 1906, 713.)

The author has examined the action of sulphoacetic acid on amines, and found that it behaves similarly to acetic acid. When sulphoacetic acid is warmed with primary amines (aniline, *p*-phenetidine, *p*-anisidine, *o*-toluidine and α-naphthylamine) neutral salts are obtained: $HSO_3.CH_2.COOH + 2RNH_2 = RNH_3SO_3.CH_2.COORNH_3$; these salts are easily decomposed at a higher temperature into the amine salt of a sulphoacetylamine:

$$RNH_3SO_3.CH_2.COORNH_3 = RNH_3SO_3.CH_2.CORNH + H_2O.$$

The yields obtained are almost theoretical. With primary amines containing acid groups, *e.g.*, *p*-aminophenol, the reaction does not take place. By the action of sulphoacetic acid on methylaniline, the methyl group is split off, and the aniline salt of sulphoacetanilide produced. These amine salts are soluble in warm water or alcohol, and in dilute acids, from which they separate out unchanged. The amine salts are converted into hydrochlorides by concentrated hydrochloric acid, and into the corresponding sodium salts by the action of sodium hydroxide.—C. E. F.

Cerium compounds; Purification of ——. N. A. Orlow. Chem.-Zeit., 1906, **30**, 733.

Ceric, in contradistinction to cerous, compounds have the property of forming a soluble, readily decomposable oxalate with excess of ammonium oxalate, analogous to that formed by thorium salts under similar conditions. This reaction affords a convenient method of preparing cerium salts free from all other rare-earth compounds. A solution of the impure oxides in warm sulphuric acid is diluted, poured into a large excess of ammonium oxalate solution, and filtered rapidly. The dark orange filtrate, containing the double oxalates of thoria and ceria (the other oxalates remaining insoluble), gradually becomes colourless on standing, owing to reduction of the ceric salt, and precipitation of the cerous oxalate formed. The thorium oxalate remains in solution, and the cerous oxalate is perfectly free from other earths. The reduction and precipitation can be expedited by reagents such as sodium sulphite. Other organic acids besides oxalic acid form double salts with tetravalent cerium, *e.g.*, double salicylate of sodium and cerium.—H. B.

Formaldehyde and formic acid; Volumetric determination of —— by means of permanganate in acid solution. H. Grossmann and A. Aufrecht. XXIII., page 830.

Citrates and tartrates; Detection of ——. J. F. Tocher. XXIII., page 829.

Ethers and esters; British duties on ——, *in* 1905–06. Ann. Rep. of Comm. of Customs. [T.R.]

Among dutiable articles there was an all-round decline, the chief item being chloral hydrate, which dropped from £1215 to £1060. Acetic ester realised £209, butyric ester £487, sulphuric ether £131 (£55 less), ethyl bromide £2, ethyl chloride £422 (£139 less), ethyl iodide £1, and transparent soap in the manufacture of which spirit has been used declined, by £23, to £77.

Hexamethylentetramine. U.S. Customs decision. Oil, Paint, and Drug Rep., Aug. 6. [T.R.]

The protest of the importers was sustained regarding merchandise invoiced as "hexamethylentetramine" on which duty was assessed at 55 cents per pound, under the provisions of paragraph 67 of the Tariff Act of 1897, as a medicinal preparation in the manufacture of which alcohol is used. The importers claimed the goods to be dutiable at 25 per cent. *ad valorem*, under paragraph 68 of said Act, as a medicinal preparation in the manufacture of which alcohol is not used. The merchandise was found to be identical with that passed upon in Gen. Appr. 6403 (T. D. 27,505), and in accordance with said decision the protest was sustained and the decision of the collector reversed with instructions to reliquidate accordingly.

United States Patents.

Borneol; Process of making ——. A. Hesse, Assignor to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat., 826,165, July 17, 1906.

See Fr. Pat. 359,547 of 1905; this J., 1906, 392.—T.F.B.

Creosote compounds. R. Berendes, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 824,901, July 3, 1906.

Alkyloxyacetyl compounds of creosote, obtained by the action of alkyloxyacetyl chloride on creosote, are colourless liquids, soluble in ether and alcohol, liberating creosote when treated with alkali hydroxides; they are said to possess valuable therapeutic properties. The ethoxyacetyl creosote compound is especially claimed: it boils from 152° to 176° C., (20 mm. pressure). (See also U.S. Pat. 822,339 of 1906; this J., 1906, 653.)—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 777.)

Mercurous oxalate emulsions. L. Castellani. Phot. Korr., 1906, **43**, 281; Chem.-Zeit., 1906, **30**, Rep. 244.

Mercurous oxalate, prepared by acting on mercurous nitrate with oxalic acid at 80° C., was washed, and made into a coagulable, white, fine-grained emulsion with dissolved gelatin and salt, the latter being essential to coagulability. Plates coated with this emulsion, then bathed in bichromate, and, when dry, exposed under a negative, were found suitable for phototype printing, and were very fine in the grain, though not standing pressure very well. No heat is required to form the grain, and the films on the used plates do not lose the property of swelling up.—C. S.

Photographic process; Investigations into the theory of the ——. Lüppo-Cramer. Phot. Korr., 1906, **43**, 80, 241; Chem.-Zeit., 1906, **30**, Rep. 244.

The substance of the negative cannot be made entirely soluble by oxidation with acid permanganate, conversion into ferrocyanide, or by chlorination with nascent chlorine or cupric chloride, though it becomes soluble when exposed to bromination, iodisation, or the conjoint

influence of silver bromide and potassium ferricyanide. The residue left on treating a negative with chromic acid is insoluble in thiosulphate, but is soluble in a strongly acid fixing bath or in ammonium thiocyanate containing sulphuric, nitric, hydrochloric, or citric acid. The author therefore differentiates two substances in the finished negative—one soluble in chromic acid, nitric acid, &c., and presumably pure silver, and one probably consisting of a solution of silver in silver bromide, rather than a sub-halide.—C. S.

ENGLISH PATENT.

Photographic plates, films and the like; Preparation and development of ——. W. F. C. Kelly and J. A. Bentham, London. Eng. Pat. 8911, April 27, 1905.

THE various substances necessary for developing photographic plates or films are applied to the back of the plate or film by aid of a suitable colloid; a preservative such as boric acid or an alkali borate is also added. The mixture may be applied as one layer, or the substances may be separated into different areas, containing, for example, the alkaline constituents in one set of areas, and the reducing agents in another. In order to avoid reflection of light from the glass, a "backing" layer may be interposed between the sensitive film and the support, or a light-absorbing substance may be incorporated with the developing constituents. When the invention is applied to "roll" films, an impervious band is rolled with the film to prevent the action of the developing substances on the emulsion. The plates or films are developed by immersion in water. (Compare Eng. Pat. 3164 of 1905; this J., 1906, 560.)—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 778.)

Nitroglycerin explosives; Uncongealable ——. F. Roewer. Z. ges. Schiess- u. Sprengstoffw., 1906, 228; Chem.-Zeit., 1906, **30**, Rep. 240.

NITRATED monochlorhydrin, being able to withstand temperatures of – 25° to – 30° C. without freezing, and being non-hygroscopic and insoluble in water and acids, is recommended as an adjunct in the composition of nitroglycerin explosives. It possesses the advantages of being easy to separate from the nitrating acid, and to wash, besides acting as a good solvent of trinitroglycerol. An addition of 5—10 per cent. of dinitromonochlorhydrin considerably lowers the freezing point of the product, and 20 per cent. gives a product that will stand very low winter temperatures. Other qualities imparted by this addition are diminished susceptibility to shock and percussion, without injuring the other properties of the explosives. An objectionable feature is that free hydrochloric acid is liberated when the explosives are detonated, but this could be ameliorated by the use of alkali nitrates or metals. Explosives prepared in the above manner have stood the test of storage for 18 months.—C. S.

Explosion; Circumstances attending an ——, *which occurred in the Corning House of the Gunpowder Factory at at Blackbeck, in the County of Lancaster on April* 30, 1906, Major A. Cooper-Key, H.M. Inspector of Explosives.

A QUANTITY of press-cake, amounting to nearly half a ton, was undergoing the process of "corning" when a violent explosion occurred, killing two men.

An examination of the débris indicated that the explosion was due to the friction of two steel surfaces owing to an ill-fitting key, by which a pinion wheel was keyed to the shaft. It appeared that the key was originally driven into position from the outside, and retained there by a coupling piece in such a manner that, provided the key was an ordinary mechanical fit, no "play" could be possible, and the shaft and pinion would be virtually one piece. A small amount of "play" would, however, soon cause a considerable "burring," and a gap such as that found, would result, in which, on starting or stopping the machine, the impact of one steel surface on another would be sufficient to explode any of the fine dust with which everything in the "corning house" is covered. The machine had been erected for six years, and the key had not been inspected during that period, and, moreover, it is doubtful whether an inspection would have revealed the misfit until the machine had been running for a considerable time.—B. J. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 780.)

APPARATUS, &c.

ENGLISH PATENT.

Gas; Apparatus for analysing ——. E. Schatz, Frankfort on Maine, Germany. Eng. Pat. 3417, Feb. 12, 1906. Under Int. Conv., May 11, 1905.

SEE Second Addition of Dec. 4, 1905, to Fr. Pat. 350,352 of 1905; this J., 1906, 778.—T. F. B.

UNITED STATES PATENT.

Gas-analysis apparatus. J. M. Morehead, Chicago, Ill. U.S. Pat. 824,999, July 3, 1906.

THE apparatus consists of a graduated explosion burette, with a bulb-shaped expansion at the lower end, connected by a three-way tap, and rubber tubing, to a water-sealed outlet and to a levelling-bottle. At the top of the burette there is also a three-way tap which serves to connect it with a funnel, and with another three-way tap, which communicates with a "storage-bulb," and "control-bottle," or with a wash-bottle.—W. H. C.

INORGANIC—QUALITATIVE.

Nitroprussides; Reaction of sulphides on ——. J. F. Virgili. Z. anal. Chem., 1906, **45**, 409—439.

A SOLUBLE sulphide, reacting on a nitroprusside, soluble or insoluble, produces a blue substance. Alkali must not be present, nor be formed during the reaction; certain salts also, by the hydrolysis of which alkali is formed—carbonates of the alkalis or alkaline earths, alkali silicates, borates, phosphates, &c.—interfere with the production of the blue colour. The blue substance appears to be a molecular addition-product of the sulphide with the nitroprusside.

With regard to the use of nitroprussides for analytical purposes, the author concludes that sodium nitroprusside is not a reagent for the sulphide-ion, but for un-ionised soluble sulphides, and is hence less sensitive than metallic salts which react with the sulphide ion. Its sensitiveness is increased by the addition of any reagent which hinders or lessens the ionisation of the sulphide; for this purpose

alkali or alkali carbonate may be employed, but ammonia is less effective than the fixed alkalis. A still further increase of sensitiveness is attained by cooling to the freezing point of the solution; but even then, reagents acting on the sulphide-ion are more sensitive. It is impossible, by means of nitroprusside, to distinguish between sulphide and sulphydrate, or to determine sulphides colorimetrically with any approach to accuracy. —J. T. D.

Ozone; Detection of —— by means of tetramethyldi-p-diaminodiphenylmethane. F. Fischer and H. Marx. Ber., 1906, **39**, 2555—2557.

Paper dipped in this reagent—so-called "tetramethyl-base-paper"—while moist, is coloured violet by ozone, whilst nitrogen oxides colour it straw-yellow. If both substances are present, an intermediate and not very characteristic tint is produced. The dry paper is useless. To detect small amounts of nitric oxide and ozone in presence of each other, the gas to be examined is led into liquid air, which dissolves the ozone, and solidifies the nitric oxide. On filtering, the presence of nitric oxide on the filter and of ozone in the filtrate, can be demonstrated by the tetramethylbase-paper.—J. T. D.

INORGANIC—QUANTITATIVE.

Zinc; Analysis of industrial ——. A. Hollard and L. Bertiaux. Bull. Soc. d'Encourag., Revue de Metall., 1906, **3**, 138—139.

If the zinc contain no arsenic, and no other reducing substance than iron, the latter can be determined by permanganate in the sulphuric acid solution of the zinc, and the lead by dissolving 10 grms. of the zinc and 10 grms. of copper in 87 c.c. of nitric acid, and depositing as peroxide (0·3 ampère).

If other substances be present, 5 grms. are dissolved in hydrochloric acid, and the solution boiled to expel arsenic; any insoluble metal is dissolved by adding a little hydrogen peroxide. The acid is nearly neutralised, and the liquid saturated with hydrogen sulphide. The sulphides are washed, dissolved in nitric acid, and evaporated to dryness, taken up with nitric acid and filtered; any tin is either weighed as stannic oxide or determined electrolytically. The filtrate is evaporated to fuming, with sulphuric acid, filtered, and the lead determined as sulphate or as peroxide. The filtrate, after adding nitric acid, is electrolysed for copper, and the remaining liquid evaporated to expel nitric acid, and made up to 300 c.c., which should contain 5 c.c. excess of sulphuric acid and sodium sulphate equivalent to 10 grms. of the anhydrous salt. It is then electrolysed for cadmium (1 ampère), using a cathode plated with cadmium. In the filtrate from the hydrogen sulphide precipitate, the iron is precipitated as hydroxide, and determined iodometrically. Arsenic is determined iodometrically after removal of the antimony.—J. T. D.

Antimony and tin; Separation of ——. A. Czerwek. Z. anal. Chem., 1906, **45**, 505—512.

Tin may be separated from antimony by precipitation as the double compound of stannic acid and phosphoric acid, but it is necessary that chlorine ions should be absent. For the analysis of an alloy, 0·5 grm. is covered with a mixture of 15 c.c. of nitric acid (sp. gr., 1·42), 15 c.c. of water, and about 6 grms. of tartaric acid, the temperature being 40°—50° C. When solution is complete, the liquid is heated to boiling, and 5—30 drops of 45 per cent. phosphoric acid (sp. gr., 1·3) are added, according to the amount of tin present. After diluting with about 300 c.c. of boiling water, and allowing to stand on the water-bath for 15 minutes, the solution is decanted on to a filter, and the precipitate washed with water containing ammonium nitrate. The precipitate is dissolved in warm ammonium sulphide, and then, after cooling and diluting largely, the tin is again precipitated by adding sulphuric acid. The mixture is allowed to stand some time on the water-bath, and the greenish-grey precipitate is then filtered off, and washed as before. The dried precipitate is added to the filter ash in a crucible, oxidised with nitric acid (sp. gr., 1·42), dried on the water-bath, ignited, and weighed as tin dioxide. The filtrate from the tin is neutralised with ammonia, and then warmed with ammonium sulphide, and acidified with acetic acid. The precipitated antimony sulphide is dissolved in ammonium sulphide, evaporated to dryness, and oxidised to antimony tetroxide in the usual way, with fuming nitric acid.

Analyses are given of alloys containing antimony and tin only, and also of those containing lead, copper, and zinc in addition. In dealing with these latter, tin is precipitated as before, and ammonium sulphide separates the other metals from the filtrate. In all cases in which antimony and tin have been obtained free from other metals by solution in ammonium sulphide, electrolytic precipitation has been found satisfactory as a preliminary to their separation.—F. Sodn.

Substances soluble with difficulty; Studies of the solubility of ——. II. Solubility of silver chloride, bromide, and thiocyanate at 100° C. W. Böttger. VII., page 806.

ORGANIC—QUALITATIVE.

Citrates and tartrates; Detection of ——. J. F. Tocher. Brit. Pharm. Conf., Birmingham, 1906. Pharm. J., 1906, **77**, 87.

Tartaric acid.—On adding a few c.c. of cobalt nitrate solution to a solution of an alkali tartrate, a fine red colour is produced, which is discharged on adding excess of sodium hydroxide solution. If the alkaline liquid be boiled, a deep blue colour appears, which fades as the mixture cools, and reappears on again heating.

Citric acid.—Alkali citrates give an immediate deep blue colour, in the cold, with cobalt nitrate solution in the presence of free caustic alkali.

Tartar emetic does not behave like other tartrates with cobalt nitrate. It produces an immediate blue colour in the cold, similar to the reaction obtained with citrates. —J. O. B.

ORGANIC—QUANTITATIVE.

Egg-yolk; Proposal for an official method for the commercial analysis of ——. Report of Turin Congress Commission. Collegium, 1906, 242—244.

The following conditions are proposed, under which the determinations of water, fat, sodium chloride, and ash in samples of egg-yolk are to be performed. Care should be taken to well shake and stir all vessels containing the egg-yolk before drawing the samples.

Water.—From 15 to 20 grms. of the sample are weighed out into a flat-bottomed basin tared together with a little dry sand and a small glass rod. The mixture is heated cautiously at first, and well stirred so as to break up all lumps; it is afterwards dried at a temperature of 100°—105° C. to constant weight.

Fat.—The dry residue is extracted in a Soxhlet apparatus with petroleum spirit (b.pt. 70°—75° C.). When the ether which siphons over is colourless, the residue is withdrawn from the apparatus, dried, powdered, and extracted for a further period. The extract is evaporated, and the residue dried for one hour at 100°—105° C. before being weighed. Should the sample contain boric acid, a portion will remain in the fat, and its quantity must be determined and allowed for.

Sodium chloride.—The residue insoluble in petroleum spirit is dried, dissolved in water, the volume diluted to 250 c.c., and the chlorine titrated in a known volume of the solution with standardised silver nitrate solution using potassium chromate as indicator.

Ash.—Ten grms. of the sample are placed in a platinum basin, dried, and carbonised at a low temperature. The mass is extracted with hot water, and the extracts evaporated in a weighed basin, whilst the carbonaceous residue is burnt to a white ash, which is added to the extract in the basin. When dry, the whole is heated for some time at a temperature of 100°—105° C. before weighing.

A difference of more than 1·5 between the percentage

amounts of sodium chloride and total ash, points to the presence of boric acid or other added mineral matter. —W. P. S.

Maple products; Determination of the lead [malic acid] value of ——. A. P. Sy. J. Franklin Inst., 1906, **162**, 71—72.

THE precipitate obtained on treating maple products with basic lead acetate, consists principally of lead malate; this precipitate is more or less copious in genuine samples, but only slight in adulterated samples. The following method of determining the "lead value" is stated to be convenient and trustworthy: A portion of the sample is treated with lead acetate, and the precipitate formed collected on a filter. After washing, both filter and precipitate are heated in a beaker with nitric and hydrochloric acids, sulphuric acid being added finally, and the heating continued until fumes are given off. If blackening occur, a little nitric acid is added. When cold, the mixture is diluted, alcohol is added, and the lead determined as usual.—W. P. S.

Malt extracts; Examination of commercial ——. E. F. Harrison and D. Gair. Brit. Pharm. Conf., Birmingham, 1906. Pharm. J., 1906, **77**, 94—95.

Total solids.—Twenty grms. are dissolved in water, and made up to 100 c.c., and the sp. gr. of the solution determined. The percentage of total solids is then calculated by the aid of the formula

$$\text{T.S.} = \frac{\text{Sp. gr} - 1000}{3{\cdot}92} \times 5$$

Maltose.—Five c.c. of the above 20 per cent. solution are diluted to 100 c.c., and 10 c.c. of Fehling's solution are titrated with this. The percentage of maltose is found by the aid of the formula $\frac{805}{m}$, where m = the number of c.c. of malt extract solution used up.

Diastase.—An amount of potato starch equivalent to 1 grm. of dry starch is weighed off, mixed in a mortar with a few c.c. of cold water, and poured into 65 c.c. of boiling water. The mortar is rinsed with a little more water, so as to make up 80 c.c. of mucilage in all, which is again boiled for one minute to ensure complete gelatinisation. The mucilage is then cooled to 40° C., and 20 c.c. of the same 1 per cent. solution of malt extract as used for the determination of the maltose are added to it. This is equivalent to 0·2 grm. of the original extract. The mixture is maintained at 40° C. for half an hour, and then boiled to stop further hydrolysis. When cold, 10 c.c. of Fehling's solution are titrated with it. From the total maltose found, the maltose introduced with the extract is deducted.

The calculations may be combined by the use of the following formula:—

$$\left.\begin{array}{l}\text{Weight of anhydrous starch}\\ \text{completely converted} \ldots\end{array}\right\} = 1{\cdot}184\left(\frac{8{\cdot}35}{n} - \frac{1{\cdot}61}{m}\right),$$

where n is the number of c.c. used in the last titration, m (as above) represents the c.c. used in the former maltose titration, and 1·184 is the factor $\frac{100}{84{\cdot}4}$ for calculating maltose into starch.

The figures given in the table for diastase represent the percentage of starch which the extract is capable of completely converting in half an hour at 40° C. Since 0·2 grm. is the weight of extract taken for the test, the above result must be multiplied by 500; or

$$\text{Diastatic value} = 592\left(\frac{8{\cdot}05}{n} - \frac{1{\cdot}61}{m}\right)$$

Proteid.—This was determined by the Kjeldahl-Gunning method.

The following table gives the results of the examination of 13 commercial samples:—

Sample.	Total solids.	Maltose.	Proteids.	Diastatic value.	Remarks.
	per cent.	per cent.	per cent.		
I.	73·2	65·4	6·7	468	—
II.	79·8	64·4	5·3	346	—
III. ...	69·8	58·5	5·5	356	—
IV. ...	77·0	54·0	3·6	10	—
V.	72·3	52·1	3·8	15	—
VI ...	95·9	82·1	5·7	89	Solid extract.
VII. ..	78·8	66·0	6·1	96	Considerable salicylate present.
VIII. .	74·3	62·5	6·1	65	Ditto.
IX. ...	73·0	47·1	3·8	17	9·5 per cent. of cane-sugar present.
X.	66·2	49·7	3·9	0	—
XI. ...	78·7	74·2	5·5	268	High maltose figure probably due to glucose.
XII ...	64·9	58·8	3·9	0	—
XIII. .	73·9	63·6	6·6	137	—

—J. O. B.

Rosin-size [in paper]; Detection and determination of —— H. Rebs. Papier-Zeit., 1906, **31**, 2158.

TURPENTINE-ROSIN (ordinary colophony) is a mixture of abietic acid with varying proportions of its anhydride. The acid is readily soluble in alcohol or light petroleum spirit, but the anhydride is nearly insoluble. For the determination of rosin in paper, 10 grms. of the sample are torn up, and heated with 25 c.c. of 10 per cent. alcoholic potash under a reflux condenser. The liquid is filtered, and the rosin is precipitated in the form of abietic acid by the addition of dilute hydrochloric acid to the filtrate. The precipitate is collected, washed with cold water, and dried at a moderate temperature. The crude product is then purified by extraction with 50 c.c. of light petroleum spirit on the water-bath. The petroleum extract is filtered, and a little ammonia is added to the solution. Ammonium abietate is thus precipitated in the form of a gelatinous mass. This is filtered off and dried on the water-bath; the combined ammonia is then driven off by carefully heating the soap by means of a very small flame, and the residual abietic acid is weighed. It is stated that the gelatinous precipitate formed by the action of ammonia on the petroleum extract, is absolutely characteristic of abietic acid, and serves for the separation of colophony from all other resin-acids, even when it is present in very small quantities.—J. F. B.

Formaldehyde and formic acid; Volumetric determination of —— by means of permanganate in acid solution. H. Grossmann and A. Aufrecht. Ber., 1906, **39**, 2455—2458.

THE authors confirm a statement of Vanino and Seitler, that formaldehyde can be completely oxidised by permanganate in acid solution in the cold; the excess of permanganate must, however, be allowed to act for an hour, otherwise too low values are obtained.

With formic acid or its salts, contact with permanganate in the cold for six hours is requisite; then the solution is warmed to 40° C., excess of standard oxalic acid solution added, and the remaining excess titrated with permanganate. The fact that formic acid is more slowly oxidised than formaldehyde seems to preclude the possibility of formic acid being a stage in the oxidation of formaldehyde; the authors consider that an addition compound is first formed, $HCOH + O_2 = H.C(O:O)OH$, which then breaks up into water and carbon dioxide.—J. T. D.

New Books.

CLASS LIST AND INDEX OF THE PERIODICAL PUBLICATIONS IN THE PATENT OFFICE LIBRARY. 2nd Edition. Darling and Son, Ltd., 34—40, Bacon Street, E. Published at the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. 1906. Price 6d.

DUODECIMO volume containing 246 pages of matter, and alphabetical index of titles, followed by a brief appendix.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

CORRECTIONS FOR DECENNIAL INDEX.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

Changes of Address

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

PROF. LIVERSIDGE, F.R.S., IN THE CHAIR.

EXAMINATION OF SOME WESTERN AUSTRALIAN BARKS.

BY E. A. MANN AND E. E. COWLES.

Of late years there has arisen a considerable industry in Western Australia through the discovery of the valuable tanning properties of the bark of the so-called "mallet" gum, and the following investigation was undertaken to determine whether the barks of any of the other commonly occurring trees of our forest areas were worthy of special attention for tanning purposes. The mallet bark has, of course, received considerable attention from leather chemists(1), but the only account which we have been able to find of the examination of other barks from this State is a report by H. G. Smith, published in the Western Australian Journal of the Department of Agriculture, Vol. XI., Part 4, 1905.

Through the courtesy of Mr. R. W. Synnot we obtained the following specimens:—

	Ordinary name.	Botanical name.	Mean thickness of bark in mm.
1	Ordinary mallet .	Eucalyptus occidentalis	7
2	Salmon gum	,, salmonophloia	15
3	Manna or wattle	Acacia decurrens	4
4	York gum	Eucalyptus loxiphleba	6
5	Morral	,, longicornis	9
6	White gum	,, redunca	13
7	Silver mallet	,, occidentalis(2)	6
8	Black mallet	,, ,, (2)	8
9	Yate	,, cornuia	8
10	Salmon gum (large)	,, salmonophloia	10
11	Salmon gum (small)	,, ,,	7

With the exception of Nos. 1, 6, and 8, none of the barks showed much signs of kino. In Nos. 1 and 8 the gum veins were very prominent. The barks were sampled by planing off a strip the full length of the sheet, which was then broken and ground to pass a 40-mesh sieve. The methods of analysis employed were those of the International Association of Leather Trades Chemists, including alterations adopted at the Leeds Conference in 1902(3), with the exception that, for estimation of non-tannins, the chromed hide-powder method of the Association of the Official Agricultural Chemists of America was used. Kaolin was not used in any filtration, as perfectly clear solutions were obtained without its use. All dryings were done at 100° C. for eight hours. The hide-powder was examined and found to contain 12·26 per cent. of nitrogen calculated to 18 per cent. moisture.

Table I. gives the results of the analyses of the samples, and Table II. (see next page) shows the behaviour of their extracts with various reagents.(4)

TABLE I.

	Grms. taken for 1000 c.c. of infusion.	Moisture percentage.	Non-tannins percentage.	Tannins percentage.
1	6	10·45	16·23	44·5
2	16	9·48	7·06	16·9
3	20	7·05	6·84	15·1
4	24	7·11	8·75	19·8
5	24	5·56	6·74	8·73
6	20	10·59	7·46	19·5
7	8	10·76	13·66	14·67
8	8	11·77	5·05	35·2
9	24	8·69	7·3	16·1
10	12	10·15	6·45	18·8
11	20	8·49	11·61	19·25

Sample No. 6 has a peculiar character. Though it apparently acts, when the infusion is the ordinary way, it does not react with hide quite like an ordinary tannin, and presumably true tannins are absent from this bark. It would appear from the above reactions that the tannins all belong to the catechol rather than to the pyrogallol class.(5)

As regards the colour of the leather produced by these various barks, the following observations may be recorded:—Nos. 1, 4, 8, 10, and 11 were similar in appearance and colour, and would probably produce a good leather of light colour. Nos. 2, 5, 7, and 9 gave a reddish tinge to the leather, and would not be considered so satisfactory as the preceding numbers. No. 3 was of indifferent quality, having a decided purplish tinge. No. 6 was very highly coloured, giving a deep brick-red coloration and harsh character. It is not to be understood, however, that we place too much reliance on this classification. We recognise that it is only by practical trial in a tanyard that the real value of a bark can be ascertained, and it is in the hope of attracting the attention of practical tanners to these barks for that purpose that these results are published. While it will be seen it must that none of the other barks are equal in value to the "mallets," and none of them rich enough for profitable use in tanning, the majority of them could probably be used with great advantage in the preparation of tanning extracts, provided that the leather produced is found on trial to be of good quality.

We have been much indebted to Mr. R. Rosenstamm, of Perth, and Mr. L. Benjamin, of Footscray Tannery, Melbourne, for advice and assistance in connection with this investigation. A further investigation has now been begun as to the percentages of tannin contained in the woods of the above trees as well as in some other Western Australian barks, the results of which we hope to publish at an early date.

(1) An exhaustive report by Professor Eitner, of Vienna, dealing with the mallet bark, and published in "Der Gerber," is not available here at the time of writing.

(2) We were unable to find out whether these mallets are distinct species, or only varieties of ordinary mallet.

PROF. LIVERSIDGE, F.R.S., IN THE CHAIR.

THE FERMENTATION OF CANE MOLASSES, AND ITS BEARING ON THE ESTIMATION OF THE SUGARS PRESENT.

BY DR. GEORGE HARKER.

The question of the determination of the sugars, and more especially of the saccharose, in cane molasses is one which has caused much discussion. On account of the large proportion of reducing sugars present in cane molasses, it is recognised that no reliance can be placed on the saccharose figure obtained by direct polarisation, since the reducing sugars present also affect the polarisation. For exact determinations recourse is generally had to the Clerget method, which is not affected by the presence of reducing sugars. In this method, after obtaining the figure for direct polarisation, the solution is inverted with acid and the polarisation again made. The reducing sugars are not affected by the acid and the difference in the two polarisations is taken to be due to the production of invert sugar from the saccharose originally present. From this difference the saccharose is calculated.

Fresh interest has been aroused recently by Remy [illegible] Chim. Soc. Dict., 1904, 21, 1902), who has

Table II.

opposed the Clerget method on the ground that the presence of the invertase present in the ferment is not so sensitive to acid in neutral as in acid solutions. Lindet, however (Bull. Assoc. Chim. Sucr. Dist., 1900, 18, 574), has shown that the error can only be a very slight one.

An important paper dealing with the whole question of the determination of saccharose in cane molasses has been published recently by H. and L. Pellet (Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 744—752). Numerous experiments have been made by the authors with different molasses, in which the reducing sugars present before and after inversion with acids were determined by means of Fehling's solution. The saccharose was thus calculated by a method independent of the optical properties of the sugars, and in all cases was found to be in very close agreement with the Clerget figure for the same sample. The authors consider that the accuracy of the Clerget method is beyond question.

Now when cane molasses is fermented, the quantity of alcohol produced is generally much less than that which is indicated by calculation from the figures of analysis for the saccharose and reducing sugars in the molasses; and it is evident that the yield of alcohol has an important bearing on the question of the determination of the sugars. In this connection an account of some experiments undertaken by the author on the fermentation of cane molasses may be of interest, as they seem to cast some doubt on the methods of analysis for the sugars present.

To account for the low yields of alcohol obtained from the fermentation of molasses several explanations have been given. Of these, apart from bacterial losses, the most important seem to be the presence of organic acids and the possible presence in the molasses of sugars fermentable only with difficulty.

Lafar has shown (Z. Spiritusind. 1895, 18, 238) that free organic acids hinder fermentation.

Bau (Z. Spiritusind. 1894. 17, 366) has discussed the resistance of beet molasses to fermentation and concludes that it is chiefly due to the presence of sugars fermentable only with difficulty. Boiling with sulphuric acid not only removes volatile acids, but also inverts such sugars as raffinose fermentable only with difficulty, and so increases the yield.

The majority of the experiments, of which an account is given in this paper, were performed upon a sample of molasses which had the following composition:—

Saccharose (Clerget)	41·52
Reducing sugars	9·26
Other organic matter	11·66
Ash	11·50
Water	26·06
	100·00
Brix	75·1
Specific gravity	1·3832

Total sugar as reducing sugar, 52·94 (43·68 + 9·26). Polarisation direct, 38·80.

After inversion with acids, 55·12 per cent. of reducing bodies, estimated by Fehling's solution, were present; subtracting from this the 9·26 per cent. present before inversion, and, following Pellet, calculating the saccharose from the difference, the figure 43·57 was obtained, which seemed to show that the Clerget figure was if anything lower than the truth. It was only as the investigation proceeded that a contrary opinion was formed.

In all the fermentation experiments, whether saccharose or molasses was employed, the solutions were always made so as to contain 10 grms. of sugar, calculated as reducing sugar, in every 100 c.c. of solution. By this means a comparison of results was rendered very easy. The volume of solution fermented was in all cases 500 c.c. The solutions were placed in bottles previously cleaned, sterilised, and dried. The mouth of each bottle was closed by a plug of cotton-wool and the bottles were then placed in a water-bath, which was kept at a temperature of 31° C. by means of a thermostat. The yeast employed for most of the experiments was pure culture yeast and was obtained from the Berlin Institute. In a few experiments ordinary brewery yeast was used.

The attenuation of the solution on fermentation was taken as a basis for calculating the yield of alcohol. The attenuation in the figure multiplied by 1000 gives the difference in the specific gravity of the solution before and after fermentation. When 19 or 20 solutions were fermented in one operation, as was often the case, it would be difficult to estimate the alcohol in each by distillation on account of the time occupied. The yield of alcohol could be calculated with close approximation by means of the following formula: $\frac{\text{attenuation} \times 100}{47{\cdot}5}$.

At the end of a number of experiments the alcohol was removed by distillation, and the yield so obtained compared with that calculated from the attenuation. The distillations were conducted with great care, a long fractionating column being used. According to Pasteur, 100 grms. of reducing sugar produce on fermentation 48·47 grms. alcohol, and as each solution of 500 c.c. contained 50 grms. of sugar, calculated as reducing sugars, the maximum yield of alcohol obtainable was 24·235 grms. The following table gives a comparison of some of the yields of alcohol actually obtained by distillation, with the yields calculated from the attenuation figures:—

Material fermented.	Attenuation obtained.	Percentage yield calculated from attenuation.	Alcohol produced.	Percentage yield calculated from alcohol produced.
			grms.	
Saccharose	43·0	90·5	22·01	90·8
Molasses	39·3	82·7	19·90	82·1
Molasses	39·3	82·7	19·81	81·75

In the case of the cane sugar the yield actually obtained was slightly above, while with molasses it was somewhat below that calculated from attenuation, and this was observed in other cases; but by adding 0·5 per cent. to the yield calculated in the case of the saccharose solutions and by subtracting 0·5 per cent. in the case of the molasses, figures were obtained which were in good agreement with the percentage yields of alcohol obtainable by actual distillation. Accordingly in calculating the yields from the attenuation figures these corrections were applied.

Fermentation of the molasses.—As the total sugar by analysis in the molasses was 52·94 per cent., each solution for fermentation (500 c.c.) contained 94·65 grms. of molasses. When the molasses was fermented in simple aqueous solution, without any previous treatment, the attenuation obtained was 38·3, corresponding to a yield of 80·1 per cent. by calculation. The yield of alcohol was not increased to a material extent by boiling the solution to sterilise it, nor by adding sulphuric acid before fermentation. The addition of Pasteur's mineral nutrient increased the attenuation to 39·3, corresponding to a calculated yield of 82·2 per cent. In a few experiments the sugar in the molasses solutions was completely inverted by treating with excess of sulphuric acid (16 grms. per 500 c.c.) at 70° C. After this treatment the acid was nearly neutralised with sodium carbonate, mineral nutrient matter was added, and the solution fermented. Although no sugar was destroyed during inversion the yield of alcohol was very little increased—attenuation 39·5. In all cases in which the molasses was fermented the fermentation was vigorous.

Although treatment with sulphuric acid may improve the yield from beet molasses, it was of very little value here, and consequently the explanation given by Bau to account for the difficulty of fermenting beet molasses cannot be applied to the cane molasses under consideration. Further, as after the acid treatment all the sugar was present as reducing sugar, the low yield obtained under ordinary circumstances cannot be due to incomplete inversion of the saccharose, as has been asserted. The maximum attenuation obtained, viz., 39·5, corresponded to a percentage yield of 82·7, so that even under the best conditions the yield of alcohol was very low.

To whatever [illegible] the molasses solutions were subjected before fermentation there was always a small quantity of some substance present in the spent wash which reduced Fehling's solution. The quantity of this, although small, was constant, and amounted to about 2·46 per cent. on the weight of molasses taken. In calculating the possible yield of alcohol obtainable from a given molasses it is always taken that the reducing sugars given by analysis are completely fermentable; but if we assume that the substance left in the spent wash, which reduces Fehling's solution, is present in the original molasses and is not formed during the fermentation, a correction must be applied to the analysis figures if we wish to know the amount of fermentable reducing sugar. Thus, in the molasses under consideration, of the 9·26 per cent. of reducing bodies present, only 6·80 can be considered as fermentable sugars; the total sugar calculated as reducing sugar falls to (52·94—2·46) = 50·48 per cent., and the percentage yield of alcohol obtainable becomes $\frac{50{\cdot}48 \times 100}{52{\cdot}94} = 95{\cdot}3$ per cent. of that originally calculated as the maximum possible.

The yield of alcohol of 82·7 per cent. actually obtained was calculated on the basis of 52·94 per cent. of fermentable sugar, but this is still considerably less than 95·3 per cent., and if, after making the allowance for the reducing substance in the spent wash, the figures of analysis for saccharose and fermentable reducing sugars are correct, then the low yield of alcohol can only be explained by the harmful effect on the fermentation of bodies either present in the original molasses or produced during the course of the fermentation.

Defecation of the molasses before fermentation.—A few preliminary experiments were made in order to determine the effect of removing organic matter by means of lead salts. To solutions of molasses, not too concentrated, basic lead acetate was added to precipitate organic matter. After filtering off the precipitate, the excess of lead was removed by sulphuretted hydrogen, and after boiling to remove this gas, the solutions were made nearly neutral and were fermented. Before fermentation a sample was taken for the determination of saccharose and reducing sugars present, and the percentage yield of alcohol was calculated from these figures. Although the solutions fermented rapidly the yield of alcohol was not improved. To avoid the accumulation of acetic acid in the solution, resulting from the employment of basic lead acetate, normal lead nitrate and lime were also used to precipitate the organic matter, but the yield of alcohol was not raised.

Fermentation of saccharose in pure nutrient solutions and in solutions of spent wash.—To determine with more certainty whether or not the presence of the non-sugar bodies in the molasses exerts a deterrent effect on the fermentation, as is constantly asserted, experiments were made in which saccharose was fermented in solutions of spent wash. For purposes of comparison cane sugar was also fermented in pure nutrient solutions under similar conditions. In these latter cases the solutions contained 47·5 grms. of pure cane sugar, equal to 50 grms. of reducing sugars in each 500 c.c., and in addition the nutrient materials necessary for the growth of the yeast cells. Pasteur's nutrient mixture was found the best of several tried, but when used by itself the fermentation of the cane sugar took several days to complete, while in the case of a molasses solution, or of a solution of cane sugar in spent wash, the fermentation was always finished in 48 hours. However, by the addition to every solution of 2 grms. of a nitrogenous yeast food sold under the name of "levurogene," which itself contained no fermentable material, the time taken over the fermentation was reduced to two or three days.

The fermentation of saccharose in the pure nutrient solutions did not proceed so regularly as was expected. In many cases the attenuation reached the figure 45·5, corresponding to a yield of alcohol of 96·3 per cent.; a considerable number varied between 45 and 45·5, but sometimes with poor fermentations the attenuation was as low as 43. The principal aim, however, was not to obtain a theoretical yield of alcohol, but to find out how much alcohol was produced when cane sugar was fermented under conditions approaching as closely as possible to [illegible] during the manufacture of fermentation [illegible]. The experiments showed that under these conditions from a definite weight of cane sugar the alcohol obtained was about 96 per cent. of the quantity obtained by Pasteur.

In the case of the fermentation of cane sugar in solutions of spent wash, the solutions were prepared by evaporating the alcohol from solutions of molasses which had been completely fermented, care being taken that the solutions were not being too strongly heated. In many cases the solutions had been allowed to stand several days after all fermentation was finished before the alcohol was removed. 47·5 grms. of saccharose were then dissolved in the solution, nutrient matter and yeast added, and the volume made up to 500 c.c. In this way a known amount of sugar was fermented in the presence of all the non-sugar bodies contained in the molasses, with the exception perhaps of the most volatile organic acids. The quantity of these removed could only have been very small, as the acidity of the solution of spent wash did not alter to any extent during the removal of the alcohol. Many experiments were made; the fermentation was always more vigorous and the results obtained more regular than with saccharose in nutrient solutions. The addition of Pasteur's nutrient improved the yield slightly, but no gain resulted from the addition of "levurogene," as the spent wash itself contained sufficient nitrogenous food for the growth of the yeast cells.

The experiments proved conclusively that the yield of alcohol obtained is just as large when saccharose is fermented in solutions of spent wash as when fermented in pure nutrient solutions, and that, consequently, *the non-sugar bodies present in the spent wash exercise no harmful influence on the fermentation.*

In some cases the attenuation was as low as 43 or 44, but in most it varied from 45 to 45·5. In one or two cases the calculated figures were checked by actual distillation of the alcohol, when it was found, as for saccharose in nutrient solution, that the yield by distillation was slightly higher than the calculated. A yield of at least 96 per cent. of the maximum (taking Pasteur's figures) was obtained.

These results gave rise to a strong belief that the low yields obtained in the case of the molasses were due to the fact that the percentage of sugars present in the molasses is much less than that shown by analysis. It might be said, however, that in the case of molasses, the bodies originally present, whatever they may be, which exercise a harmful influence on the fermentation, are themselves altered during the course of the fermentation, and that consequently, although pure sugar gives a theoretical yield of alcohol when fermented in spent wash, it might not do so if fermented in the original molasses.

Experiments already described had shown that a solution containing 47·5 grms. of cane sugar in 500 c.c. gave an attenuation of 45·5, and one containing 94·45 grms. of molasses, in 500 c.c. an attenuation of 39·5. Hence, if the fermentation of saccharose proceeds as well in molasses solutions as in pure nutrient solutions, 28·75 grms. of cane sugar and 37·22 grms. of molasses in 500 c.c. should give an attenuation of 41·5.

The average figure for seven separate determinations was 41·3, giving further evidence that on fermentation the sugar in a molasses solution is completely converted into alcohol.

Assuming that this is the case, the amount of fermentable sugar present can be calculated. On the basis of 52·94 per cent. of fermentable reducing sugar, it was found that the best results obtained from the fermentation of the molasses gave a yield of 82·7 per cent. of alcohol; when pure saccharose was fermented in spent wash under similar conditions the yield of alcohol was 96 per cent., or, in other words, only a small proportion of the sugar was not converted into alcohol. Assuming that this slight loss of sugar takes place also in the case of the molasses, we may consider that

$$\frac{82{\cdot}7 \times 100 \times 52{\cdot}94}{96} = 45{\cdot}63$$

is the percentage of fermentable sugar, in terms of

reducing sugar, present in the molasses. This quantity is 39·2 per cent. by the methods given by analysis.

Determination of carbon dioxide as dioxide on fermentation of the molasses.—In order to determine whether the fermentation of the molasses was normal, the ratio of the carbon dioxide to alcohol was obtained. The ratio was also determined for pure nutrient solutions of saccharose.

The solutions for fermentation were prepared as previously described, and out of each 500 c.c., 50 c.c. were removed for the estimation of the carbon dioxide. The remainder, to act as a check, was placed in a bottle and fermented under the same conditions as the smaller quantity. The 50 c.c. were placed in a small flask, which was immersed in water kept at 31° C. The carbon dioxide was estimated from the loss of weight sustained by the flask and attached drying apparatus. In the first experiments on molasses and saccharose, the gas which escaped was absorbed in potash bulbs to ensure that the loss was due to carbon dioxide, but this precaution was found unnecessary. A current of dry air removed the last of the carbon dioxide from the apparatus.

"	39·3	2·00	1·993	0·996

Each 50 c.c. of solution contained 5 grms. of sugar, in terms of reducing sugar, it being understood that in the case of molasses the solutions were always made up on the assumption that the analysis figures were correct, and that the content of the molasses in fermentable sugar was 52·94 per cent. Pasteur gives for the fermentation of 5 grms. of reducing sugar, carbon dioxide, 2·338 grms., alcohol, 2·424 grms.; ratio, carbon dioxide: alcohol = 1:1·037.

The fermentations of the nutrient saccharose solutions were never so good as those obtained by Pasteur, hence the ratios of carbon dioxide to alcohol were lower. It is interesting to note, however, that the ratios with molasses were quite as high as those obtained from the nutrient saccharose solutions.

Inversion of sugar in molasses by means of invertase.—Although all the evidence derived from the fermentation experiments seemed to indicate the presence of less sugar than was given by analysis, the quantity of reducing bodies produced by inversion with acids supported the analysis figures. Consequently it was of importance to determine, if possible, the amount of reducing bodies produced in molasses by the action of invertase.

The invertase was prepared by mixing a weighed quantity of fresh yeast with water, and keeping it at a temperature of 60° C. for some time. The solutions for inversion were made so as to contain 10 grms. of sugar calculated as reducing sugar per 100 c.c., and generally 200 c.c. were inverted in each experiment. The temperature of inversion was between 55° C. and 60° C. Saccharose either in aqueous solution or dissolved in spent wash was inverted rapidly and completely.

Turning now to molasses, the action of invertase was found to be much slower. In solutions of saccharose in spent wash 98 per cent. of the sugar added was inverted in 24 hours, while 48 hours were required for the maximum inversion in molasses. If the figures of analysis for saccharose and reducing sugars are correct, there should have been present, after inversion with invertase, 10 grms. of reducing sugars in each 100 c.c. of solution, but the quantity obtained actually was only 86 to 87 per cent. of this.

Now it has already been shown that the quantity of alcohol obtained on the fermentation of the molasses accounts for about 86 per cent. of the sugar indicated by analysis, and this quantity should all be present after inversion with invertase; but to this must be added the unfermentable reducing substance found in the spent wash after fermentation of a molasses solution, which of course does not contribute to the production of alcohol, but is present in the solution. Its amount was found to be 2·46 per cent., calculated on the molasses, or 4·65 per cent. of the total sugar, in terms of reducing sugar. Hence, after inversion with invertase, at least 91 per cent. of the sugar indicated by analysis would be expected. The amount found in the experiments was not more than 86 to 87 per cent. But when the solutions, after inversion with invertase, were fermented, the yield of alcohol obtained was some 2 or 3 per cent. lower than usual, so that evidently a little fermentable sugar had been destroyed during the prolonged inversion. The amount of the loss was easily calculated by subsequent fermentation, and allowing for it, the total quantity of reducing bodies after inversion was found to be about 90 per cent. (9 grms. per 100 c.c.) of that indicated by the analysis. Of this 4·65 per cent. is unfermentable, and the quantity of fermentable sugar in the molasses, in terms of reducing sugar, becomes 45·18 per cent. The figure obtained before from consideration of the alcohol produced from the molasses was 45·68 per cent., and although both these figures are only approximations, the agreement between them made it clear that when the molasses was treated with invertase just that quantity of reducing sugar was formed which was necessary to produce the quantity of alcohol obtained when the molasses was fermented. Consequently a considerable portion of what analysis indicated as saccharose was not inverted by invertase, and was in reality not that substance.

Although the action of invertase on molasses took a longer time than when cane sugar was inverted in a solution of spent wash, the results obtained were fairly concordant. This was also found in the case of another molasses treated in a similar way, though with one particular sample no results of value could be obtained, as the action of invertase speedily came to an end, there being evidently something present which inhibited the action of the enzyme. The experiments with invertase confirmed in a striking manner the results obtained earlier in the investigation, and left no room for doubt that the analysis figure for saccharose was considerably too high.

The quantity of reducing bodies produced by the action of acids was very much greater than by that of invertase, but on subsequent fermentation the yield of alcohol—allowing for the slight destruction of fermentable sugar during inversion with invertase—was no greater. Hence the reducing bodies produced by acids and not by invertase were not fermentable sugars, and were therefore not derived from saccharose.

H. and L. Pellet, in the paper referred to above, laid great stress on the close agreement of the figures for saccharose in cane molasses obtained by the Clerget method and by calculation from the reducing bodies present before and after inversion with acids. Thus for the molasses under consideration, we have:

Saccharose (Clerget).	Reducing bodies after inversion.	Reducing bodies before inversion.	Difference.	Saccharose calculated.
41·52	55·12	9·26	45·86	45·67

The authors mentioned obtained a much closer agreement for the molasses examined by them, and they regard it as a complete confirmation of the accuracy of Clerget's process, but since a considerable proportion of the reducing bodies obtained by inversion with acids are not fermentable sugars, no figure for saccharose of any value can be deduced from them.

The conclusion of the investigation was, therefore, that the possible yield of alcohol from cane molasses indicated by analysis is considerably higher than that which can be obtained by fermentation, and that this is due to the fact that the analytical figures overstate the amount of fermentable sugars actually present.

By making use of the figures obtained in some of the experiments it becomes possible to apply a correction

to the ordinary analysis. Thus for the molasses under consideration, the quantity of fermentable reducing sugar being 6·80 instead of 9·26, the figure for saccharose can be obtained by first subtracting this from the total fermentable sugar, expressed in terms of reducing sugar. For this two figures were arrived at, viz., 45·63 and 45·18. Taking the mean of these, viz., 45·41, and subtracting 6·80, we obtain 38·61 as the figure for saccharose expressed in terms of reducing sugars. Whence saccharose itself, $\frac{38{\cdot}61 \times 95}{100} = 36{\cdot}68$ per cent.

On making these corrections we have—

	Original analysis.	Corrected analysis.
Saccharose	41·52 ..	36·68
Sugars reducing	9·26 ..	6·80
Other organic matter ..	11·66 ..	18·96
Ash	11·50 ..	11·50
Water	26·06 ..	26·06
	100·00 ..	100·00
Total sugar as reducing sugar	52·94 ..	45·41

If we call the possible yield of alcohol calculated from the total sugar in the original molasses 100, then the yield possible from the corrected analysis is only 85·8.

One of the most interesting but puzzling questions in connection with the investigation related to the manner in which the character of the unfermentable bodies, appearing as saccharose in the original analysis, changes during the course of the fermentation. If these bodies did not alter they could be estimated in the spent wash after fermentation, and there would be no difficulty in accounting for the low production of alcohol from the molasses. But the fact that only a small quantity of reducing bodies is found in the spent wash even on inversion of this with acids makes it appear as if a loss of sugar actually took place.

When measured quantities of liquid were removed from a solution of molasses at different stages of the fermentation, and were treated with acid, and the reducing bodies so produced estimated, it was found that they diminished rapidly during the earlier stages of the fermentation.

Thus:—

Attenuation.	Reducing bodies (expressed in terms of reducing sugars) grms. per 100 c.c.
0·0	10·3
0·5	9·5
2·5	8·62
5·5	8·28
Fermentation complete ..	0·7

Hence when alcoholic fermentation had only just started (atten. 0·5) the quantity of reducing bodies which could be produced by inversion with acids had already become very considerably diminished and was very little in excess of the quantity (9·0 grms.) produced by treating the molasses with invertase.

A similar observation was made in the experiments with invertase. When inversion with invertase was complete an estimation of the reducing bodies produced by inversion with acids, including those already produced by invertase, showed that the quantity of these was not much in excess of these latter, whereas before the action of the invertase the quantity of reducing bodies produced by the acid treatment was much greater. Thus if we call the quantity of reducing bodies produced from a given weight of molasses by the action of acids 10·3 and the quantity by invertase 8·7 grms., then after inversion with invertase further treatment with acids produced a total quantity of only 9·0 grms., showing that a considerable change in the character of the bodies invertable by acids and not by invertase had taken place. This was quite apart from any loss of fermentable sugar during the inversion, which loss, as proved by subsequent fermentation, was very small. Besides, if it had been fermentable sugar which was disappearing, owing to any bacterial action, the loss should have increased with the time, but it did not. Sufficient evidence has already been given that the loss of fermentable sugar due to bacterial action during the fermentation of the molasses would only have been very small, since even prolonged treatment with sulphuric acid failed to materially raise the yield, and further, if bacteria were present we should expect the wash to become acid. Under ordinary circumstances, however, the increase of acidity in the solutions during fermentation is slight.

It appears probable that the bodies, whatever they may be, which appear as saccharose in the analysis and which are inverted by acids but not by invertase, are decomposed by some enzyme in the yeast during the earlier stages of fermentation.

Discussion.

Mr. J. A. Schofield asked if the ordinary methods of analysis when applied to beet molasses also gave high results. It was rather strange that the sugar that seemed to disappear should not only have the rotatory power of saccharose, but should also yield bodies with the same reducing power as invert sugar.

Dr. R. Greig-Smith suggested that the apparent loss of sugars might arise from these particular bodies being readily decomposable, and thus supplying cell material for the growing yeast. During his researches on vegetable gums he had found some bodies that yielded, on hydrolysis, reducing substances that were not sugars capable of forming ordinary osazones, for the compounds melted at too low a temperature, and yielded tarry bodies with acetic acid. Possibly some similar substance might be present in molasses. With regard to sugar in molasses fermenting more quickly than pure sugar aided by Pasteur's nutrient, he thought this was due to the high proportion of salts present. He deprecated the assumption that some "enzyme" had been acting, when as a matter of fact the nature of the change was simply unknown.

Dr. Harker, in reply to Mr. Schofield, said that in beet molasses reducing sugars were absent, and raffinose was the only substance known to be present that made a correction necessary in the polariscopic reading. With regard to Dr. Greig-Smith's remarks, he thought the disappearance of the apparent saccharose was too rapid to be explained as due to its being used as food for yeast cells. He was of opinion that the rapidity of fermentation in molasses was due to the large proportion of nitrogenous yeast foods, rather than to the salts.

PROF. A. G. GREEN IN THE CHAIR.

DETERMINATION OF MINERAL ACIDS IN VINEGAR.

BY F. W. RICHARDSON AND J. LEONARD BOWEN.

There are upon the market at the present time vinegars which in outward appearance resemble malt vinegar, but which are really fabricated articles, and consist of mixtures of acetic acid, burnt sugar, some little salt and more or less malt vinegar with water. As long as these are not sold as malt vinegar and do not contain objectionable substances such as free mineral acids, the law cannot prevent their sale. It is another matter when the article sold is described as malt vinegar. As genuine malt vinegars vary considerably in their composition, the amounts of nitrogen and phosphorus being an exception, it is not easy to fix a standard, and, probably no two analysts would agree as to what malt

vinegar should be. To make a really satisfactory analysis of a vinegar—to ascertain whether it has been produced largely by the assistance of surrogates, or whether it is a pure article—a very full analysis is required. We do not suppose that there would be any injury to health from using vinegar containing 0·1 per cent. of sulphuric acid; but some limit must be established, and if it is clearly proved that the addition of any quantity, however small, of sulphuric acid is really not necessary, the exclusion of mineral acids is undoubtedly advisable.

The estimation of mineral acids in vinegar is not easy. With the exception of Hehner's original method, the published processes are all, in our opinion, unreliable. In König's recent work ("Die Untersuchung der landwirtschaftlich und gewerblich wichtigen Stoffe," page 702) are several references to this question, and we do not hesitate to affirm that not one of the methods cited is capable of giving even reasonably approximate results. In the *Analyst* for August, 1903, is a paper by Schidrowitz upon the detection and estimation of mineral acid in acetic acid and vinegar. The method is based upon the supposition that the addition of ethyl alcohol to a solution of acetic acid entirely prevents the reaction of the latter with the indicator. We were quite unable to make anything like an accurate estimation of free sulphuric acid when this was mixed with pure acetic acid and water. We used a white vinegar which we made to contain 5 per cent. of acetic acid and 0·1 per cent. of sulphuric acid. As the following table shows, we could get any results we wished for by varying the amounts of alcohol and vinegar. A very pure methyl orange was used as indicator, and 25 c.c. of the vinegar were taken in each experiment:—

	92 per cent. alcohol.	Ratio of vinegar to alcohol.	*N*/10 sodium hydroxide.
	c.c.		c.c.
1	15	1 to 0·6	10·0
2	20	1 ,, 0·8	5·0
3	25	1 ,, 1·0	3·0
4	30	1 ,, 1·2	2·5
5	50	1 ,, 2·0	nil.

Schidrowitz says, "The best results are obtained by adding an equal volume of alcohol to the solution to be titrated, and subsequently 1 c.c. of alcohol for every 3 c.c. of deci-normal alkali run in."

Had the end reactions been other than hopelessly indefinite, we should have found, according to our third result, about two-thirds of the actual amount of sulphuric acid present.

It is obvious that a method which depends upon the exact adjustment of the amounts of an adjunct to attain an end reaction, which at the best is indefinite, is scarcely suited to the requirements of a busy analyst. The complete suppression of all acidity by the addition of a further amount of alcohol shows how very dubious the results obtained by such a method must be.

From a large number of experiments we are of opinion that even such a good process as that suggested by Hehner and described in the first volume of the *Analyst*—the method which is taken as the standard—when wrongly applied, may miss free mineral acids in vinegars. In general the Hehner method consists in adding standard alkali to some of the vinegar, evaporating to dryness, reducing the residue to ash at a low temperature, treating the ash with a measured quantity of deci-normal sulphuric acid (which must be in excess of the original alkali used) and noting the loss of acidity, which represents an equivalent amount of alkali neutralised by the free mineral acids in the vinegar. When acetate of soda or potash, which would be formed when standard alkalis are added in sufficient quantities to vinegar, are incinerated, they produce alkali in quantity corresponding to the alkali used, so that the acetic acid does not interfere with the process.

As a number of chemists find the present Hehner method is not properly given, and the reader is advised to simply ascertain the alkalinity of the ash after evaporation with a measured quantity of standard alkali. Here a serious error may arise on account of the conversion of calcium salts such as the malate into the carbonate. When the ash is treated with an excess of decinormal sulphuric acid, as Hehner directs, of course the carbonate of the lime exerts its alkaline effect, and the mistake does not occur.

The ash of a genuine malt vinegar consists to the extent of more than half its weight of potassium phosphate; but it is wrong to say that the ash of malt vinegar contains free phosphoric acid. The fact of the presence of so much phosphate of potash in vinegar when made largely from malt should be taken into consideration, lest complications occur interfering with the accuracy of any process devised for the purpose of estimating free mineral acids, as it is well known that should any of the phosphoric acid become liberated during the carrying out of the method, it reacts with standard soda or potash with methyl orange as indicator in a very different way to ordinary mineral acids.

Thomson has demonstrated that when normal potash is added to a solution of phosphoric acid the pink colour of methyl orange is discharged when dihydrogen potassium phosphate is formed, so that one only really obtains one-third of the actual amount of phosphoric acid in the titration with methyl orange. It is also to be noted that when phenolphthalein is used the end reaction occurs when dipotassium hydrogen phosphate is produced. We simply instance these particulars because they show that it is not so easy to estimate the absolute amount of free sulphuric acid which may have been actually added to a vinegar; thus, if any alkaline acetate were present, as well as free sulphuric acid, and the Hehner process were applied, to the extent of the percentage of acetate present there would be a corresponding disappearance of free sulphuric acid in the analytical result.

It may be said that this would be a rather desirable feature, as sulphuric acid would really decompose the sodium acetate with the production of acetic acid and the formation of sodium sulphate, and no longer be present as free acid; still, there are no facts to show that, when sulphuric acid is present to the extent of only one in a thousand, it really does decompose any small amounts of alkaline acetate in the cold, although on boiling to dryness and incineration such decomposition does occur.

One would like to know whether in the human organism the sulphuric acid in such cases does really act as such, despite the presence of the acetate. That the ash of vinegar really does contain normal potassium phosphate is sufficiently evident from such an experiment as the following: 100 c.c. of a pure malt vinegar gave an ash—obtained by charring—the soluble constituents of which showed an alkalinity equal to 5·2 c.c. of *N*/10 sulphuric acid, to methyl orange, followed by an acidity equal to exactly half this amount—*viz.*, 2·6 c.c.—to phenolphthalein.

On the average, a good malt vinegar will contain 0·2 per cent. of mineral matters expressed as "ash," and our analyses show that 0·16 of this will consist of potassium phosphate (with a little sodium phosphate) and 0·025 per cent. of calcium phosphate.

In the estimation of free mineral acids, *e.g.*, sulphuric acid, what error would be introduced by these quantities of phosphates? (1) In the presence of methyl orange, and when the neutralisation point has been reached, sulphuric acid reacts with potassium phosphate as follows:—

$$K_3PO_4 + H_2SO_4 = K_2SO_4 + KH_2PO_4.$$

1 c.c. of *N*/10 sulphuric acid is equivalent to 0·01062 grm. of tripotassium phosphate. Therefore 100 c.c. of the vinegar would contain sufficient phosphate to account for 15·06 c.c. of *N*/10 sulphuric acid, whence 15·06 × 0·0049 = 0·0738 per cent. = 1 part of sulphuric acid in 1356 parts of vinegar is masked by the phosphate of potassium.

(2) 0·025 per cent. of calcium phosphate would produce the following somewhat complex change when estimated by the full Hehner process:—

The sodium hydroxide becomes inactive in the incineration process and reacts with the calcium phosphate, calcium [illegible]

by sulphuric acid, with formation of sodium dihydrogen phosphate. The calcium carbonate formed neutralises exactly as much sulphuric acid as the equivalent amount of soda which has helped to produce it; therefore, the sodium phosphate formed exerts extra alkaline, i.e., acid-masking action, and 1 c.c. of $N/10$ sulphuric acid = 0·008207 grm. trisodium phosphate. Also 0·025 grm. tricalcium phosphate = 0·02644 grm. trisodium phosphate = 3·22 c.c. $N/10$ sulphuric acid = 0·0158 grm. of sulphuric acid for tricalcium phosphate in ash, 0·0738 grm. of sulphuric acid for tripotassium phosphate in ash, making a total of 0·0896 grm. of sulphuric acid, i.e., a combined obscuration of one part of free sulphuric acid in 1116 parts of the vinegar. It is therefore obvious that if we wish to estimate the actual amount of free mineral acid added to a vinegar, we shall require to know the amount of phosphoric acid present in a combined state in the vinegar itself. If we assume all the phosphoric acid to be present as potassium phosphate, and introduce the calculation given above, only a very slight error can arise.

As an illustration, we give the results of an analysis of a genuine malt vinegar. We made one portion to contain 0·098 per cent. and another 0·049 per cent. of sulphuric acid, and we also submitted the untreated vinegar to the same process as the acidified samples.

In each case, 25 c.c. of vinegar were mixed with 25 c.c. of $N/10$ sodium hydroxide, and the solution was evaporated to dryness, and the residue heated over a low Bunsen flame to produce a thoroughly charred mass. The heat used must not be sufficient to cause fusion. The black ash is cooled and treated with 5 c.c. of neutralised peroxide of hydrogen, as we find this absolutely necessary to prevent the liberation of hydrogen sulphide, which would interfere with the accuracy of the result. Then 50 c.c. of $N/10$ sulphuric acid are added, and the mixture boiled. After filtration and thorough washing of the carbonised mass, the filtrate is coloured with methyl orange or lacmoid, and made neutral to $N/10$ sodium hydroxide, the number of c.c. being noted. We acidify with a few drops of $N/10$ sulphuric acid and boil for five minutes to remove all carbon dioxide. After neutralisation by $N/10$ sodium hydroxide, phenolphthalein is added and the acidity to $N/10$ sodium hydroxide determined. We give an example of the method of calculation.

After carrying through the first part of the above process, 26·1 c.c. of $N/10$ sodium hydroxide were required to make neutral to lacmoid. After expelling carbon dioxide, the solution was treated with phenolphthalein, and then required 2·0 c.c. of $N/10$ sodium hydroxide. The first part, that is, the part previous to the addition of phenolphthalein, and with the exception of our improvement in regard to hydrogen peroxide, is virtually the Hehner method.

25 c.c. of $N/10$ sodium hydroxide were added to the vinegar, and 26·1 c.c. were required to neutralise the filtrate, giving a total of 51·1 c.c. of alkali; 50 c.c. of $N/10$ acid was added to the ash, thus the excess of alkali was 1·1 c.c. 1·1 c.c. $\times$ 4 $\times$ 0·0049 = +0·0216 per cent. free sulphuric acid by the Hehner method. Our method carries the results and calculation further. We have an excess of decinormal alkali of 1·1 c.c., but we must add twice the number of c.c. of alkali required after adding the phenolphthalein, and the result will therefore be—

	+1·1 $N/10$ alkali by Hehner method	
2·0 c.c. $N/10$ alkali $\times$ 2 + 4·0	„ „ R. & B.	„
Total ..	+5·1 „ „	in 25 c.c. vinegar

neutralised by mineral acid; therefore = 0·0999 per cent. sulphuric acid, instead of 0·0980 per cent. actually present. Error +0·0019 per cent.

Tabulated, the results appear as follows:—

Actual per cent. of sulphuric acid added.	With methyl orange.		With lacmoid.	
	Hehner method.	R. and B.	Hehner method.	R. and B.
A 0·098	+ 0·033	+ 0·099	+ 0·0216	+ 0·0999
B 0·049	— 0·033	+ 0·064	—0·0450	+ 0·0450
C nil.	— 0·080	+ 0·023	—0·0980	+ 0·0040

Here it is obvious that by the Hehner method as much as 0·065 or 1 part of sulphuric acid in 1540 of vinegar would be entirely obscured, while by our method the total amount of acid originally added is estimated. Of course it may be said that the analyst is only asked to determine the amount of free sulphuric acid actually present, and that our method does not do this. We are of opinion that this contention has to be proved. The mere fact that the sulphuric acid does not appear as such in the residue does not for a moment show that it is not present in a free condition in the original vinegar; in any case the sulphuric acid, if it does act at all upon the potassium phosphate, liberates an equivalent quantity of phosphoric acid, which in itself is a mineral acid, and its presence as such in vinegar is no more to be tolerated than sulphuric acid. It is certainly advisable that a process should exist which will enable one to ascertain the actual amount of free mineral acid which has been deliberately added to a vinegar by the manufacturer, and we claim that our method enables us to do this. On the whole we are inclined to the contention that lacmoid is a more valuable indicator than methyl orange where great accuracy is required. As is well known, carbon dioxide does exert some influence upon methyl orange, but with lacmoid the carbonic acid is always expelled by boiling, and it is possible to ascertain the end reaction to a single drop of deci-normal acid. The results with lacmoid are more reliable than those with methyl orange, the latter results tending to be somewhat too high, and we think that this is due to the action of the carbon dioxide.

Temperatures; Method and apparatus for gauging ——. F. L. Morse, Trumansburg, N.Y., Assignor to H. H. Westinghouse. New York. U.S. Pat. 826,594, July 24, 1906.

A neutral-tinted screen, 5, is illuminated with light of any desired tint, and the body, 10, the temperature of which is to be judged, is inserted through the aperture, 8, and viewed through the eye-opening, 9. Light from the lamp, 11, is directed by the mirror upon the neutral-tinted screen, 5, and is tinted to the desired colour by being passed through the colour screen, 12. The latter consists of a simple or multiple glass cell with parallel faces, and is filled with a suitable coloured liquid. On looking through the opening, 9, it is possible to judge when the object has the same tint as the illuminated screen.—W. H. C.

Desiccating or evaporating apparatus. W. E. Jaques, Grand Rapids, Mich., Assignor to International Desiccating Co., Chicago, Ill. U.S. Pat. 827,183, July 31, 1906.

A CYLINDRICAL drying chamber, *a*, having a conical bottom, *e*, is surrounded by a heating jacket, *f*, and has a vapour escape-opening, *c*, in the top, underneath which is arranged an open-topped deflecting cone, 10, provided with a drain pipe, 11. The liquid to be evaporated is forced, under pressure, from the reservoir, M, through the pipe, *p*, out of the nozzle, r^2, in an upward direction, and is heated and sprayed by a jet of air, heated by being passed through the coil, *m*, and which issues from the nozzle, *k*, and strikes against the jet of liquid from r^2, at an angle. The liquid is evaporated in the chamber, and the vapour escapes through the top opening, *c*, whilst the solid particles, being deflected by the cone, 10, fall back into the chamber, their descent being retarded by the action of the fan, 22, carried on the cross-bars, 16, and driven by the mechanism, 23, 25, 26. The dried solids pass out of the chamber by the opening, *d*, into the right- and left-handed screw-conveyor, 33, 34.—W. H. C.

Desiccating apparatus. J. C. McLachlan, Chicago, Ill. U.S. Pat. 827,172, July 31, 1906.

IN order to obtain the solid matter of a solution in the form of a dry powder, the liquid is sprayed from an atomising jet by the aid of heated, compressed air, into a tall chamber. The latter is open at the top to allow the escape of the vaporised liquid, and is surrounded by a heating jacket. It is of such a height that the solid particles which fall to the bottom, are removed from the influence of the vapour of the liquid during the latter part of their descent.—W. H. C.

Filter; Centrifugal ——. T. S. Patterson, New York. U.S. Pat. 827,265, July 31, 1906.

A DRUM provided with a series of concentric, perforated, frusto-conical partitions, pitched alternately in opposite directions, and attached at their smaller ends to the bottom or top of the drum, is mounted on a vertical axis so that it can be rotated in a casing. The partitions are covered with filter cloth, and the drum has outlet and

outlet openings in the bottom and top, opposite the wider ends of the conical partitions. The casing is provided with steam inlet and outlet pipes, and with a drain pipe at the bottom.—W. H. C.

Filter. J. T. H. Paul, Assignor to E. Goldman and Co., Chicago. U.S. Pats. 827,389 and 827,390, July 31, 1906.

See Eng. Pats. 2992 and 2991 of 1906; this J., 1906, 683.—T. F. B.

Separator; Centrifugal ——. J. J. Berrigan, Orange, N.J. U.S. Pat. 827,903, Aug. 7, 1906.

The apparatus consists of a horizontal cylinder, mounted on bearings so that it can be rotated, and having another horizontal cylinder fixed eccentrically within it. The inner cylinder is divided into a number of chambers by conical partitions, all placed with their smaller ends in the same direction. The mixture of solids and liquid is fed into the inner cylinder at one end, and enters the larger end of the first cone. Here some of the liquid is separated from the solids, and is drawn off, the solids being delivered through the smaller end into the next cone, where the process is repeated. The solids pass from cone to cone, becoming drier as they advance, and are finally delivered into a shoot from the last cone.

—W. H. C.

FRENCH PATENT.

Evaporation, concentration, distillation, and drying of liquids. A. Montupet and L. Jamin. First addition, dated Feb. 7, 1906, to Fr. Pat. 339,177, Nov. 21, 1903 (this J., 1905, 144).

The addition relates to an improved method of regulating the supply of live steam, and consists in employing several "injector-mixers" arranged in groups. When it is desired to reduce the supply of live steam, one or more of the injectors are shut off, leaving the others to work at full pressure.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 804).

Acetylene; Reactions of —— with acidified solutions of mercury and silver salts. J. A. Nieuwland and J. A. Maguire. J. Amer. Soc. Chem., 1906, **28**, 1025—1031. See Brit. Assoc. Rep., 1904, "On Double Acetylides," Major Edwards and Dr. W. R. Hodgkinson, this J., 1904, 954.

The authors have obtained a number of acetylene-mercury and acetylene-silver compounds by passing the purified gas into solutions of the metal salts acidified with the acid contained in the radical of the salt. Amongst the compounds obtained were: acetylene-mercuric chromate, acetylene-mercuric chlorate and perchlorate, acetylene-mercuric cyanide, acetylene-mercuric nitrate, acetylene-mercuric acetamide, and acetylene-mercuric bromate; these substances are not necessarily explosive unless there is present in the compound an acid grouping that is itself unstable, such as chloric or perchloric acid. They all give off aldehyde when heated with dilute acids, or even with water. With solutions of silver salts, similar compounds were obtained. Those yielded by acid solutions of silver fluoride, fluosilicate, and fluoborate were all explosive. With silver chromate no precipitate was obtained. Acetylene-silver phosphate appears to be a very stable compound, and differs considerably from the other silver compounds. Acetylene-silver perchlorate is, even in the moist condition, almost as explosive as nitrogen iodide. Acetylene-mercuric fluosilicate and fluoborate could not be obtained, the boron and silicon of the acids either taking no part in the reaction, or being removed by the acetylene.—W. P. S.

Incandescence mantles; New process of manufacturing —— in which copper-cellulose is used as fabric. W. Bruno. Z. angew. Chem., 1906, **19**, 1387—1389.

Mantles made of copper-cellulose are impregnated with solutions of thorium and cerium, then treated with reagents to convert the nitrates into hydroxides, and finally burned out for use. The essential step is the conversion of the nitrates into the hydroxides. Instead of converting the nitrates by means of ammonia, the impregnated fabrics may be treated with hydrogen peroxide at 60° C. in acid solution. This converts the thorium nitrate into insoluble hydroxide; cerium nitrate is not converted, but dissolves in the peroxide solution. The fabric, however, mechanically retains sufficient cerium salt. The author states that mantles made according to the peroxide process do not consist of thoria and ceria, but of thorium peroxide, Th_2O_7, and a cerium peroxide.

Coals and lignites; Determination of volatile combustible matter in ——. E. E. Somermeier. XXIII., page 870.

Coke production of the United States. Bd. of Trade J., Aug. 16, 1906. [T.R.]

The Geological Survey reports that the amount of coke manufactured in the United States in 1905 was 28,777,794 tons (of 2240 lb.) as compared with 21,125,986 tons in 1904, an increase of 7,651,808 tons or 36·22 per cent. As a result of the demand created by the unprecedented production of pig-iron in nearly every iron-making district of the United States, the average price per ton advanced from 2.18 dols. in 1904 to 2.52 dols. in 1905. In 1905 there were 519 coke-making establishments, which owned 87,564 ovens, against 507, owning 83,599 ovens in 1904. Of the total number of completed ovens in the United States in 1905, 3159, or 3·6 per cent., were of the by-product recovery type, and the total amount of coke made in these ovens was 3,091,382 tons, or 10·74 per cent. There were under construction at the close of 1905, 4751 ovens, of which 417 were of the retort by-product type.

ENGLISH PATENTS.

Coking ovens; Impts. in ——. E. Ledoux, Sheffield, and the Simon-Carvès Bye-Product Coke Oven Construction and Working Company, Ltd., Manchester, Eng. Pat. 4990, March 1, 1906.

The coking oven is heated by a range of vertical flues, the coking chambers being disposed between these flues. The gas is supplied from a common gas main, with a single longitudinal gas outlet to each flue separately, and the supply is controlled by dampers which can be operated from the end of the "canal" by the aid of a suitable tool. The air flues, placed below the coking chambers, have separate openings to each vertical flue provided with dampers, which may likewise be controlled from the oven front by the aid of a suitable tool. A partition-wall in the lower part of the vertical flue, prevents the air and gas from being mixed and burned before they reach the place where the heat is required, which place is at the base of the coking chamber.—R. L.

Coke ovens; Impts. in ——. M. E. Bellberg, Cleveland, U.S.A. Eng. Pat. 8030, April 2, 1906. Under Int. Conv., April 8, 1905.

See U.S. Pat. 804,053 of 1905; this J., 1905, 1220.—T. F. B.

Coke and Gas; Manufacture of ——. J. Armstrong, London. Eng. Pat. 1642, Feb. 15, 1906. Under Int. Conv., June 20, 1905.

To obtain a dense coke in the manufacture of illuminating gas, coal is carbonised in a high and narrow chamber oven with thin walls, heated on the outside by a mixtu of gas and compressed air, which forces the gas high u in the heating flue, the air being preheated in seconda regenerative flues. The coal is fed into the bottom pa of the chamber by means of a ram acting in an upwa direction, and supplied from the sides by means of a feedin worm, whereby the fresh coal passes into the hottest por of the chamber. The ram is provided with an ambe head, which may be cooled by means of a water-jacke whilst the heavy hydrocarbons are decomposed in th hottest region of the oven, a gas free from tar and naphtha can be abstracted from the top. The coke can be cooled by means of a water-jacket at the top of th

[illegible] and [illegible] ... [illegible] ... [illegible] ...

portion of colloidal oxides or hydroxides of difficultly fusible metals. For example, 5 to 20 parts of colloidal oxide of tungsten are mixed with 95 to 80 parts of the plastic masses formerly described, and the threads obtained are converted into the crystalline state by heating them to a white heat in a reducing atmosphere. The plastic masses containing colloidal oxides or hydroxides may be used for making conductive connections between filaments and supply conductors, by applying them (according to Eng. Pat. 15,462 of 1905; this J., 1906, 307) in a dilute state to the joints, and afterwards heating to a white heat in a reducing atmosphere.—H. B.

UNITED STATES PATENTS.

Agglomerates [fuel] and agglutinants; Process of making ——. R. A. Le Maître, Brussels. U.S. Pat. 826,948, July 24, 1906.

SEE Fr. Pat. 356,961 of 1905; this J., 1906, 10.—T. F. B.

Furnace; Roasting or oxidising ——. C. E. Dewey, Assignor to The American Zinc and Chemical Co., Denver, Colo. U.S. Pat. 828,095, Aug. 7, 1906.

THE body of the furnace is provided with chambers arranged above each other, a vertical rotating shaft being located centrally in the furnace. Rabble arms, provided with ploughs or stirrers, are connected with the shaft, which is geared to a journaled shaft below the furnace. A track projecting upwards, and consisting of two separated members, is arranged outside the furnace. An outlet conduit communicates with the lower chamber of the furnace, and extends downwards from it, the lower extremity of this conduit being closed by a shoot pivoted and weighted; this shoot has a depending portion projecting into the space between the two members of the track. A bucket carrier slides on the track members, and carries a bucket pivoted so as to tend to tip it inwards, and prevented by a guide from tipping until it has passed a certain elevated point. The bucket carrier is alternately raised and lowered by suitable connection with the operating-shaft. The depending part of the shoot lies in the path of the bucket, the shoot being carried downwards by the descending bucket so as to allow the conduit to discharge into the bucket.—A. G. L.

Gas; Method of manufacturing ——. J. E. Allen, Columbia, Ohio, Assignor to A. C. Ellis, Pittsburg, Pa. U.S. Pat. 826,511, July 17, 1906.

AIR, compressed and heated, is driven through successive portions of heated petroleum oil, and the residual oil, from which the light hydrocarbons have been extracted, is heated in presence of a porous, non-oleaginous, carbonaceous substance, until vaporised, the resulting vapour being mixed with the first product. The gas is afterwards subjected to the action of heated, porous, non-oleaginous, carbonaceous matter, by passing it through a mass of such substance.—C. S.

Illuminating gas; Apparatus for the manufacture of ——. C. W. Bilfinger, Brooklyn, N.Y., Assignor to Columbia Engineering Works, and A. P. Bachman, New York. U.S. Pat. 827,075, July 31, 1906.

A VERTICAL cylindrical retort is set in a flue, and has its sides heated by gases from an external furnace. The retort has a removable cover at the top and a branched outlet pipe at the bottom; one branch of the latter is horizontal, and is normally closed by a plug, and the other passes vertically upward to the purifying and storage apparatus. The carbonaceous material to be distilled is contained in a "cartridge" or cylindrical vessel, open at the top, which is lowered into the retort by a derrick, and stands vertically on the bottom in such a manner that an annular space, of equal dimensions all round, is left between it and the walls of the retort. The "cartridge" is consequently heated only by radiation, through the annular space, from the walls of the retort, and the gas given off leaves the "cartridge" at the top, and passes down through the annular space to the outlet pipe at the bottom of the retort.—W. H. C.

Gas; Apparatus for manufacturing ——. P. I. Cohen, New York. U.S. Pat. 827,084, July 31, 1906.

THE claim refers chiefly to the method of regulating the supply of liquid or semi-liquid material which is converted into gas by passage through a coil heated in a furnace. The pipe which supplies steam to the pump used for forcing the liquid into the coil, has a governor connected to a device, or valve, on the delivery pipe to the coil. In this way the admission of steam to the pump is regulated by the delivery of oil, and a constant and regular feed is obtained.—W. H. C.

Gas; Process of producing ——. H. Gerdes, Berlin, Germany, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 827,862, Aug. 7, 1906.

THE claim is for the production of a gaseous fuel practically free from tarry matters. The raw fuel is distilled in the upper part of the charging tube or bell of the producer, and the distilled gases produced are drawn off and burnt with excess of air to ensure complete combustion. The products of combustion, along with any excess of air, are then passed back to the lower part of the producer, where they pass through a layer of incandescent fuel from which all volatile matter has been previously driven off. The resulting gas is drawn off separately, and is said to be free from tarry matters.—W. H. C.

Gas-purifying apparatus. S. F. Seager, Assignor to American Suction Gas Producer Co., Lansing, Mich. U.S. Pat. 826,691, July 24, 1906.

THE purifier is formed of two concentric cylinders, the gas entering through an inlet at the bottom of the inner cylinder, and leaving by an outlet at the bottom of the outer cylinder. The gas passes upwards through the inner cylinder, which is packed with coke, and is washed by liquid from a spraying nozzle at the top. It then passes down through the annular space between the two cylinders, and is further purified by passing through purifying material, supported on grids.—W. H. C.

Gas; Apparatus for purifying ——. T. Redman, Bolton, Bradford. U.S. Pat. 826,747, July 24, 1906.

SEE Eng. Pat. 12,659 of 1904; this J., 1905, 611.—T. F. B.

Gas calorimeter. H. L. Doherty, Madison, Wis., Assignor to Combustion Utilities Co., New York. U.S. Pat. 828,306, Aug. 14, 1906.

Carbide; Manufacture of ——. H. L. Hartenstein, Constantine, Mich., Assignor to Electro-Chemical and Development Co., Pierre, S.D. U.S. Pat. Reissue, 12,519; Original Pat. 819,222, May 1, 1906 (this J., 1906, 544). Aug. 7, 1906.

POWDERED limestone is calcined, and to the still hot lime, carbonaceous material is added, and the mixture is subjected to fusion, with exclusion of oxygen. Or, to the heated mixture of lime and carbonaceous material, a superheating flux, such as a mixture of calcium carbide, manganese dioxide, bituminous coal, aluminium and potassium chlorate, is added, and the whole subjected to fusion.—E. S.

Reducing compounds and producing carbides. E. F. Price, Assignor to Union Carbide Co. U.S. Pats. 826,742—826,745, July 24, 1906. XI*A*., page 853.

FRENCH PATENTS.

Gas for illuminating, heating, and power purposes; Process and apparatus for the manufacture of ——. H. S. Elworthy. Fr. Pat. 361,450, May 8, 1905.

SEE Eng. Pat. 7713 of 1905; this J., 1906, 527.—T. F. B.

Gas; Production of combustible —— *free from tar.* Deutsche Banke-Gas Ges.m.b.H. Fr. Pat. 363,348, Feb. 16, 1906.

THE fuel is charged into a tube which descends nearly to the grate-bars of the producer shaft, from which the gas is drawn off by a tube at the upper end. The tube

vapours given off in the upper part of the charging tube are drawn off by means of an injector through a tube which passes through the wall of the producer, then extends downwards, and finally again enters the producer, air being drawn in through an opening at the bottom of the vertical part of the tube. The mixture of air and gas is injected into the hottest part of the producer, or the reduction zone, where the tarry vapours are completely burnt and gasified.—W. H. C.

Gas; Process and apparatus for washing ——, *particularly for completely eliminating sulphuretted hydrogen from lighting gas.* E. Ott. Fr. Pat. 363,539, Feb. 22, 1906. Under Int. Conv., March 17, 1905.

THE gas is treated with successive small portions of the washing liquid, and each portion of liquid is immediately removed from contact with the gas before the addition of a fresh portion of washing liquid. This is done to prevent the return of any of the previously absorbed impurities to the gas. The gas, in each stage of the treatment, is drawn through an injector by the washing liquid, which is delivered under pressure, so that a very intimate contact between the gas and liquid is obtained.—W. H. C.

Incandescence [*electric*] *lamps; Filaments for* ——. A. Just and F. Hanaman. Second Addition, dated Feb. 5, 1906, to Fr. Pat. 347,661, Nov. 4, 1904. (This J., 1905, 431, 1220.)

THE impregnated filaments are first treated with an acid to convert the salts of molybdenum or tungsten into molybdic or tungstic acid. The acids are then converted into their respective metals by the subsequent treatment described.—W. H. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 805.)

Petroleum Spirit ["*Benzine*"]; *Explosions of* ——, *and the Martini-Hueneke process.* Effenberger. J. Gasbel., 1906, **49**, 689.

THE Martini-Hueneke process consists in replacing the air in benzine storage vessels, which are always kept underground, by carbon dioxide or other indifferent gas or gaseous mixtures. A special system of service pipes is also arranged which allows no escape of benzine, in case of a breakage. There are also automatically closing valves provided. The system works so successfully that, in one case, the storage "without a protecting zone" of 17,500 litres of benzine in the Westphalian mining district, in another of 15,000 litres in the heart of the city of Berlin, was permitted by the authorities.—R. L.

Emulsifying mineral oils, and the manufacture of mineral oil soaps; Process for ——. J. C. Fell. Eng. Pat. 14,294, July 11, 1905. XII., page 856.

UNITED STATES PATENTS.

Tar; Treatment of —— *for the manufacture of pitch and recovery of light oils.* W. Oppenheimer, Ewell. U.S. Pat. 827,113, July 31, 1906.

SEE Fr. Pat. 334,472 of 1903; this J., 1904, 55.—T. F. B.

Oil from oil-coated fines; Process for distilling off the ——. E. B. Kirby, Rossland, Canada. U.S. Pat. 825,909, July 17, 1906.

THE oil-concentrated "mineral fines" are fed into a retort, and heated to a temperature suitable for distilling off the oil, the feed of the concentrates through the heat zone being regulated automatically by disposing the charge in such a manner that the concentrates adhere to the supporting medium so long as they are wet, but slip down when dry. Means are provided for collecting the concentrates, and clarifying oil from the distilled vapours.—T. F. B.

FRENCH PATENT.

Antiseptic; A new —— [*from petroleum*], *and method of making the same.* C. Trocquenet. Fr. Pat. 362,990, Feb. 5, 1906. XVIIIC., page 863.

GERMAN PATENT.

Distillation of moist materials such as peat, wood, coal; Process for the ——. A. Jaba. Ger. Pat. 165,611, June 1, 1904.

THE moist goods, before passing into the still, are conveyed through a drying chamber, wherein they are dried by a current of air. The moist effluent air from the drying chamber is dried by passing it through an air-condenser, then warmed by leading it through a jacket surrounding the still, and again passed through the drying chamber. The air used for cooling in the air-condenser is also passed through the drying chamber, and is then used, together with fresh air, for cooling the distillation products from the still in separate coolers, the effluent air from which is also passed through the drying chamber. Dry air is systematically withdrawn from the plant, and used for burning fuel in the furnace by which the still is heated. The uncondensable distillation-products, after being used for cooling the distillation residue, may be burnt in the furnace. —A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 807.)

Arylamines; Conversion of aromatic ketones into ——. M. Prud'homme. Rev. Gén. des Mat. Col., 1906, **10**, 225—226.

THE author has previously shown (this J., 1906, 64) that reduction products (anthranols) of hydroxyanthraquinones, when treated at the ordinary temperature with aqueous solutions of ammonia, are transformed into imino compounds. He now finds that hydroxyanthraquinones are directly transformed into the corresponding imines by the action, at about 200° C., of ammonium salts of organic acids, in the presence of glycerol. Thus, alizarin (0·3 grm.), when fused with ammonium formate, oxalate, tartrate, citrate, &c. (1 grm.) or ammonium carbonate (1·5 grm.), and glycerol (4 grms.), yields a compound, "alizarinimine," which dyes a weak iron mordant in a blue shade. With ammonium thiocyanate (5 grms.), alizarin (1 grm.), in the absence of glycerol, gives at 159° C., a compound which dyes the same iron mordant in a greyish purple colour. The sulphur of the thiocyanic acid, it would appear, enters into reaction, as the same or a similar compound is formed when a little sulphur or sodium sulphide is added to the melt containing alizarin, glycerol, and the ammonium salt of an organic acid.

Tetramethyldiaminobenzophenone reacts imperfectly with ammonium carbonate, but readily with ammonium thiocyanate and the ammonium salts of organic acids, forming Auramine.

Alizarin Yellows A and C (B.A.S.F.), when fused with ammonium salts of organic acids, yield dyestuffs which dye the customary mordants in shades of yellow and olive, differing from those given by the original dyestuffs. The new compounds dissolve in alkali solutions with a green colour, whilst the alkali solutions of the original dyestuffs are yellow or yellowish-orange.

The conversion of hydroxyanthraquinones into the corresponding imino compounds may be effected by the following methods:—

(1) The action, at high temperatures and under pressure, of ammonia dissolved in absolute alcohol. (Friedländer's Fortschritte, V. Bayer and Co.) (See also this J., 1906, 584.)

(2) The action, at the ordinary temperature, of a dilute

aqueous solution of ammonia on the reduction-compounds (anthranols).

(2) The action, at about 200° C., of normal ammonium salts of organic acids, in the presence of glycerol.—E. B.

Diazoamines and aminoazo compounds; Influence of substitution on the formation of ——. Part V. s-Dimethyl-4.6-diamino-m-xylene. G. T. Morgan and A. Clayton. Chem. Soc. Trans., 1906, **89**, 1054—1058.

It has been shown previously that aminoazo compounds can be obtained from primary aromatic meta-diamines containing substituents in both the para positions with respect to the amino groups, although the reaction takes place less readily than when one of these para positions is still unoccupied (Chem. Soc. Trans., 1902, **81**, 86; 1905, **87**, 935, 944; this J., 1902, 36; 1905, 795). The present communication deals with the effect of partial alkylation of the amino groups in a dipara-substituted meta-diamine, it having been found (Chem. Soc. Trans., 1902, **81**, 656) that complete alkylation prevents the formation of an azo compound. *s*-Dimethyl-4.6-diamino-*m*-xylene was prepared from 4.6-diamino-*m*-xylene, the latter being first converted into *s*-dibenzenesulphonyl-4.6-diamino-*m*-xylene by means of the Schotten-Baumann reaction, and this in turn methylated, and the methyl derivative hydrolysed by heating with 15 parts of concentrated hydrochloric acid in a sealed tube for five hours at 160° C. On cotton cloth impregnated with diazotised Primuline, *s*-dimethyl-4.6-diamino-*m*-xylene produces a reddish-brown ingrain azo colour. With diazotised *p*-nitraniline it yields about 10 per cent. of *p*-nitrobenzene-5-azodimethyl-4.6-diamino-*m*-xylene and about 25 per cent. of a diazoamino compound, the formation of the azo compound probably being as follows:—

$$(CH_3)_2C_6H_2(NH.CH_3)_2 \rightarrow$$
$$NH(CH_3).C_6H_2(CH_3)_2.N(CH_3).N_2.C_6H_4(NO_2) \rightarrow$$
$$(NO_2)C_6H_4.N_2.C_6H(CH_3)_2(NH.CH_3)_2.$$

By the interaction of *p*-nitrobenzenediazonium chloride and 5-bromo-*as*(4)-dimethyl-2.4-diaminotoluene, also a diazoamine and an aminoazo compound are produced; and it may, therefore, be accepted that the dimethylation—both symmetrical and unsymmetrical—of a dipara-substituted meta-diamine greatly hinders, but does not entirely prevent, the introduction of a diazo residue into the aromatic nucleus of the diamine.—A. S.

Colouring matters [Dyestuffs]; Prohibition of the use of injurious —— in Austria-Hungary. [T. R.] XIII*A*, page 857.

English Patents.

Dyestuffs of the triphenylmethane series; Manufacture of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 25,498, Dec. 7, 1905.

Ethyl-4-alkyldiaminodiphenylmethanemonosulphonic acid may be obtained in good yield by the action of formaldehyde on a mixture of dimethyl- or diethylaniline with dimethyl- or diethylaniline-*m*-sulphonic acid. The diphenylmethane derivative is oxidised to the corresponding leuconol (*e.g.*, by means of lead peroxide and dilute sulphuric acid), which is then condensed with ethyl- or methyl-ethylanilinesulphonic acid, and the resulting leuco-compound oxidised, for instance, by lead peroxide and acetic acid. The resulting "acid" dyestuffs dye unmordanted wool clear blue to violet shades, fast to alkali.—T. F. B.

Compounds of the Anthracene series [Nitrobenzanthrones]; Production of new ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 12,518, May 29, 1906.

Benzanthrone and benzanthrone compounds, other than dyestuff derivatives (for the nitration of which see U.S. Pat. 796,259 of 1905; this J., 1905, 912), are acted upon by nitrating agents, with the production of nitro-derivatives.—E. B.

United States Patents.

Dyestuff; Green anthracene ——. R. E. Schmidt, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 826,760, July 24, 1906.

See Fr. Pat. 358,271 of 1905; this J., 1906, 260.—T. F. B.

Anthraquinone aldehyde, and process of making same. M. H. Isler, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 828,741, Aug. 14, 1906.

See Eng. Pat. 16,632 of 1905; this J., 1906, 868.—T. F. B.

French Patents.

Dyestuff especially adapted to the manufacture of lakes; Process for producing a monoazo ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,434, May 3, 1905.

See Eng. Pat. 9325 of 1905; this J., 1906, 65.—T. F. B.

Arylsulphamides; Process of making nitro-derivatives of aromatic ——. Act.-Ges. f. Anilinfabr. First Addition, dated May 5, 1905, to Fr. Pat. 349,566, April 2, 1904.

See Eng. Pat. 9074 of 1905; this J., 1906, 65.—T. F. B.

Dyestuffs derived from "naphtène" [naphthalene]; Production of black ——. Badische Anilin und Soda Fabrik. Fr. Pat. 361,447, May 5, 1905.

See Eng. Pat. 9547 of 1905; this J., 1905, 725.—T. F. B.

Indigo pastes; Process for preserving fermentable ——. Badische Anilin und Soda Fabrik. First Addition, dated Jan. 29, 1906, to Fr. Pat. 348,292, Feb. 4, 1904. Under Int. Conv., Jan. 2, 1906.

See Eng. Pat. 1954 of 1906; this J., 1906, 470.—T. F. B.

Dyestuff; Process for making a black ——, a tanning material or a second black dyestuff, and other useful products from coal or lignite. D. Lerman, B. B. D. Schwartz, and P. Pikos. Fr. Pat. 363,244, Feb. 13, 1906.

See Eng. Pat. 3107 of 1906; this J., 1906, 806.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 808.)

Colouring matters [Dyestuffs]; Prohibition of the use of injurious —— in Austria-Hungary. [T. R.] See XIII*A*., page 857.

English Patents.

Vegetable fibre for spinning or other purposes; Preparation of ——. B. Summers, Port Huron, Michigan, U.S.A. Eng. Pat. 2330, Jan. 30, 1906.

Linen, hemp, and other bast fibres are separated from the woody portions of the stems from which they are obtained, by a process which consists in subjecting the latter to prolonged artificial refrigeration, *e.g.*, for a period of from sixty to a hundred hours, at a temperature of 0°—10° F., and then breaking the woody parts of the stems and removing the fibres from these, *e.g.*, by a passage through a "cleaning" machine, while the stems are still in a frozen condition. For the proper working of the "breaking" machine, and to obtain the fibres in as perfect a state as possible, the stems, when operated upon, should contain a certain amount of moisture, which may be introduced into them, if necessary, either before or after they are refrigerated.—E. B.

Silk, artificial; Apparatus for the manufacture of ——. H. E. A. Vivenet, Lyon-Monplaisir, France. Eng. Pat. 14,067, June 19, 1906. Under Int. Conv., June 20, 1905.

See U.S. Pat. 822,155 of 1906; following these.—T. F. B.

Red [Thioindigo Red], on textile fibres; Dyeing and printing ——. Kalle und Co., Aktiengesellschaft, Biebrich-on-the-Rhine. Eng. Pat. 14,261, June 21, 1906. Under Int. Conv., June 26, 1905.

See Fr. Pat. 359,400 of 1905; this J., 1906, 426.—E. B.

Calico, paper and the like printing. W. Longley, Whalley Bridge, near Stockport. Eng. Pat. 19,328, Sept. 25, 1905.

Colour mixtures for use in printing calico, paper, &c., are prepared by dissolving a basic dyestuff in acetic acid or other suitable solvent, and adding a 3—6 per cent. aqueous solution of the gelatinous matter extracted from Irish moss, and also phenol or other phenolic compound or source of phenol, the latter to enable the mixture to be made homogeneous.—T. F. B.

Ornamental effects on woven fabrics [Flock printing]; New or improved means for producing ——. Tootal Broadhurst Lee Co., Ltd., and A. Brookes, Manchester. Eng. Pat. 27,048, Dec. 28, 1905.

Ornamental effects, in imitation of those produced by sewing upon tissues narrow velvet or other materials, are obtained by printing in adhesive substances stripe or other patterns on tissues, and then dusting upon them flocks or fluff "such as may be produced from wool or like materials." These adhere only to the printed parts. The non-adhering flocks are blown off, or otherwise removed from, the tissues, leaving the patterns in relief upon the latter. The flocks before use may be dyed in black or other colours.—E. B.

Absorbent materials, textiles, paper, or other lamellar materials; Improved method for treating, or impregnating —— with resins, fatty acids, or the like. H. O. Brandt, Manchester. Eng. Pat. 23,787, Nov. 18, 1905. Under Int. Conv., Nov. 19, 1904.

The materials are treated with dissolved ammonium compounds of resinous or fatty acids, and then heated to a temperature at which the ammonia is expelled, leaving the free resinous or other acid on the material. Suitable filling, weighting or finishing substances may be added to the impregnating solution, and they are fixed on the material by the acids liberated during the heating process; or powdered metal, glass, sand, or similar substance, may be sprinkled on the impregnated material, and fixed by the heating process.—C. S.

Soap for use in finishing woollen goods; Improved ——. J. Proude, Halifax, Yorks. Eng. Pat. 3864, Feb. 16, 1906.

A suitable quantity of ordinary white curd soap is heated in a steam-jacketed pan. When the soap boils, about 0·074 per cent. of Aniline Violet 8B, dissolved previously in water, is added, and thoroughly mixed with it. It is then cooled and cut up as usual. One pound of this coloured soap is mixed with every 5, 6, 7, or more pounds of the white curd soap, used in milling the fabric. The better the quality of the latter, the less the quantity of coloured soap needed to remove all natural tints and to produce a perfectly white article.—W. P. S.

Drying fabrics; Vacuum apparatus for ——. E. Gessner, Aue, Germany. Eng. Pat. 7928, April 2. 1906.

In order to prevent air from entering the suction chamber through the portions of the suction slot not covered by the goods to be dried, the slot is provided with slides adapted to close it from beneath, and adjustable lengthwise of the slot. The entire width of the slot is also covered from above by means of strips of fabric fastened lengthwise, at suitable angular intervals, around a rotating roller, the strips of fabric, which hang freely, hence falling successively, and being drawn one after the other transversely across the slot, in the direction in which the fabric to be dried is passing. The moisture removed from the fabric collects in a suitable chamber provided with valves or cocks, by which it can be alternately put in communication with the suction chamber and the outside, thus enabling the suction chamber to be [illegible] A sieve or filter mounted in the suction chamber serves to arrest hairs or other matter drawn into the chamber with the moisture.—T. F. B.

United States Patents.

Threads; Apparatus for the production of artificial ——. E. W. Friedrich, Blaton, Belgium. U.S. Pat. 827,[illegible], July 31, 1906.

See Fr. Pat. 357,172 of 1905; this J., 1906, 70.—T. F. B.

Artificial silk; Apparatus for the manufacture of ——. H. E. A. Vittenet, Aurce sur Loire, France. U.S. Pat. 828,155, Aug. 7, 1906.

Apparatus for forming a filament of metamorphosed cellulose is provided with a closed "fixing" tube, having a small orifice for the passage of the filament, and tubes attached for supplying and exhausting a fixing gas. The fixing tube comprises two concentric tubes having elongated slots, and flaring radial slots in their tops, one tube being adapted to turn relatively to the other, so as to close or open the tube by bringing the slots into or out of register. —E. S.

French Patents.

Dyeing wound spindles, cops, bobbins, &c.; Machine for —— Gebr. Wansleben. Fr. Pat. 363,079, Feb. 8, 1906. Under Int. Conv., March 1, 1905.

See Eng. Pat. 3194 of 1906; this J., 1906, 586.—T. F. B.

Dyeing fabrics; Apparatus for ——. E. A. F. Zillessen. Fr. Pat. 363,366, Feb. 17, 1906.

See U.S. Pats. 813,478 and 813,479 of 1906; this J., 1906, 372.—T. F. B.

Ketone sulphoxylates; Manufacture of ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 363,485, Feb. 16, 1906. Under Int. Conv., Sept. 30, 1905.

See Eng. Pat. 4073 of 1906; this J., 1906, 474.—T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page 908.*)

English Patent.

Dyeing of wood and similar pulp. W. Longley, Whalley Bridge, near Stockport. Eng. Pat. 19,256, Sept. 21, 1905.

A dilute solution (*e.g.*, 1 to 2 per cent.) of the gelatinous substance extracted from Irish moss or analogous seaweed, is added to the usual dye-bath for paper and similar pulp. The following quantities serve for dyeing [illegible] of wood pulp:—5 lb. of the basic dyestuff in suitable solution; 4 lb. of resin soap, containing excess of alkali and dissolved in 10 galls. of water; 4 lb. of alum dissolved in 10 galls. of water, and a solution of 1 lb. of the gelatinous matter in 10 galls. of water. It is stated that the addition of the gelatinous substance causes the dye-bath to be completely exhausted, and also removes all the [illegible] alum from it, leaving an innocuous effluent.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS AND NON-METALLIC ELEMENTS.

(*Continued from page 811.*)

Chamber gases; Detection of nitrous oxide in ——. W. Hempel and O. Heymann. Z. Elektrochem., 1906, 12, 600—604.

In the course of a laboratory study of the chamber process it was found that if steam, oxygen, and sulphur dioxide are simultaneously brought, in the required quantities, into a glass vessel containing nitric oxide, nitrogen, and oxygen, exceptionally large quantities of nitrous oxide are produced. The conclusion to be drawn is that the steam should only be introduced gradually, as is done

case in technological practice. An apparatus was devised for detecting the presence of minute quantities of nitrous oxide in chamber gases. Briefly described, the method consists in cooling the gases to the temperature of liquid air, after their compression to about 10 atmospheres. The gases then separated into two fractions, one of which contains the condensable nitrous oxide. This is subsequently estimated by causing its dissociation by explosion with oxy-hydrogen gas, and noting the increase in volume.

Analysis of exit gases from several works showed the presence of from 0·063 to 0·25 per cent. of nitrous oxide, and a calculation is given showing that 0·1 per cent. of nitrous oxide corresponds to an expenditure of 1·11 kilo. of nitric acid per 100 kilos. of sulphuric acid, and thus it is probable that the greater part of the loss of nitre may be ascribed to the formation of nitrous oxide.—R. S. H.

Hydrogen peroxide and potassium persulphate; Study of the reaction between ——. J. A. N. Friend. Chem. Soc. Trans., 1906, **89**, 1092—1101.

By determinations of the relative amounts of hydrogen peroxide and potassium persulphate decomposed in a given time, and by determinations of the rate of decomposition, it was found that the reaction between these two substances: $H_2O_2 + K_2S_2O_8 = 2KHSO_4 + O_2$, is unimolecular, owing to the formation of a highly unstable intermediate addition compound. The intermediate compound may be isolated in an impure form by evaporating a mixture of hydrogen peroxide and potassium persulphate over sulphuric acid. The presence of sulphuric acid has a retarding effect on the reaction between the two substances, as also have the sulphates of sodium, potassium and manganese; the last-named, however, slightly accelerates the reaction towards the end. The reaction is accelerated by colloidal platinum, the hydrogen peroxide undergoing rapid additional decomposition.—A. S.

Aurous halides; Compounds of ammonia with ——. F. Meyer. Compt. rend., 1906, **143**, 280—282.

Liquid ammonia reacts with aurous chloride, bromide, and iodide, forming colourless compounds. The bromine compound is very unstable, but the others are quite stable at − 28° C., having respectively the formulæ, $AuCl,12NH_3$ and $AuI.6NH_3$. At the ordinary temperature they lose ammonia, and leave the compounds, $AuCl,3NH_3$ and AuI,NH_3 respectively. The iodine compound can also be formed by passing ammonia over aurous iodide at the ordinary temperature. Aurous bromide similarly yields $AuBr,2NH_3$. All these compounds are decomposed by water, with formation of ammonium halide and metallic gold.—J. T. D.

Boron sulphide; Preparation of —— from ferroboron. J. Hoffmann. Z. angew. Chem., 1906, **19**, 1362—1363.

Ferroboron, containing 20 per cent. of boron, is heated in a glass tube to above 400° C. in a stream of dry hydrogen sulphide. The boron sulphide formed, along with some sulphur, condenses chiefly in the hinder portions of the tube, and any escaping vapours are caught in an ice-cooled U-tube. The substance remaining after the reaction still contains some boron, besides iron and sulphur. Boron sulphide is not sensibly dissolved by carbon bisulphide, and the product can therefore be purified from sulphur by means of this reagent. The method is much less costly than that of Wöhler and Deville, in which amorphous boron is used.—J. T. D.

Nitric acid; Technical production of —— from nitrous gases. J. Klaudy. XIA., page 852.

Nitric acid in commercial hydrochloric acid; Determination of small quantities of ——. B. N. Gottlieb. XXIII., page 849.

Nitric acid; Determination of —— in air, and some of the reactions involved. Le Blanc. XXIII., page 869.

English Patents.

Nitric acid; Apparatus for the oxidation of the nitrogen of the air for the purpose of obtaining —. O. H. U. Brünler, Leipzig-Gohlis, Germany. Eng. Pat. 5852, March 10, 1906.

The furnace is placed, mouth downwards, within a closed, pressure-resisting vessel, partly filled with water, and supplies of compressed oxygen, and of combustible gas or oil, coal-dust or the like, are admitted through inlets opposite to one another. The nitrogen is either mixed with the oxygen or is introduced through a separate pipe. The issuing jets of burning gas are said to gyrate within the furnace, whereby a rapid combustion is produced, and a temperature approaching 3000° C. is attained. The flame, issuing from the narrowed mouth of the furnace, is shown as burning under water in a pointed form. Means are provided for withdrawing the nitric acid solution thus formed, and for conveying away the gaseous products insoluble in water. Compare Eng. Pat. 5901, of 1900; this J., 1906, 811. Reference has been directed to Eng. Pats. 9855 of 1898; 16,506 of 1901 (this J., 1902, 970); and 25,748 of 1903.—E. S.

Carbonic acid; Processes for solidifying ——, *and apparatus therefor.* E. G. Elworthy, Administratrix of late H. S. Elworthy, St. Albans. Eng. Pat. 2450, Jan. 31, 1906. Under Int. Conv., Jan. 31, 1905.

See Fr. Pat. 355,503 of 1905; this J., 1905, 1231.—T. F. B.

Heating and evaporating solutions [Brine], and apparatus therefor. J. Hargreaves, Farnworth-in-Widnes. Eng. Pat. 16,035, Aug. 5, 1905.

The pan, *a*, has a sloping bottom, *d*, and is heated by the steam pipes, *b*, above which is a false-bottom or "table," *c*. The liquid to be evaporated is supplied, preferably under considerable pressure, through the perforated pipe, *k*, and circulates in the direction indicated by the arrows, under the "table," *c*, and over the upturned end, *f*. Here it begins to cool, and deposits crystals on the upper surface of *c*, which become larger in size the further they are deposited from *f*. The liquid flows over the partitions, *h* and *i*, which serve to prevent the crystals from getting beneath the table, *c*, and blocking the coils. The crystals are allowed to accumulate until they have attained sufficient size to be ready for removal. A modification is claimed, in which the pan is built over a flue, and heated by direct fire.—W. H. C.

Sodium monosilicate; Manufacture of crystallised ——. W. N. Bacon, London. Eng. Pat. 24,226, Nov. 23, 1905.

Sodium carbonate and silica are heated together in such proportion as to form a silicate having the composition, Na_2SiO_3, the solution of which, in water, concentrated until a temperature of about 219° F. is reached, cooled, and then stirred, yields the crystallised monosilicate, $Na_2SiO_3,9H_2O$. Or, the same product is obtained by adding the necessary proportion of sodium hydroxide and water to a strong solution of commercial sodium silicate to constitute the monosilicate, and stirring to [illegible] crystallisation.—E. S.

Hydrosulphites [Hyposulphites]; Manufacture and production of stable dry ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 26,380, Dec. 18, 1905.

FRESHLY precipitated and dry calcium hyposulphite is mixed with quicklime, and is then washed with a liquid miscible with water, such as alcohol; or the washing may precede the addition of the lime. Or, the calcium hyposulphite may be stirred with a mixture of alcohol and lime. The quicklime may be replaced in the process by other alkaline earths, or by a dry alkali hydroxide, the proportion of which may be varied, but should not be less than 10 per cent. The product, however obtained, should be dried, *in vacuo*, preferably at an "elevated temperature." (Reference is made to Eng. Pat. 18,852 of 1900; this J., 1901, 988).—E. S.

Bleaching medium; Apparatus for producing a gaseous ——. F. H. Loring. Eng. Pat. 22,101, 1905. XI*A*., page 853.

UNITED STATES PATENTS.

Hydrochloric acid and calcium carbide; Process of making ——. W. H. Seamon, El Paso, Tex. U.S. Pat. 826,614, July 24, 1906.

A GASEOUS hydrocarbon, particularly acetylene, is passed through fused calcium chloride, which is thus converted into calcium carbide. The hydrochloric acid set free in the process is collected.—E. S.

Sulphur trioxide; Process of making ——. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 828,268, Aug. 7, 1906.

A SUBSTANCE capable of forming sulphur trioxide on oxidation, such as sulphur dioxide, is oxidised by the action of an oxide of nitrogen, such as nitrogen tetroxide, in the presence of a substance, such as carbon dioxide, capable of being dissociated by the action of and by the absorption of heat, the proportion of the ingredients being so adjusted as to prevent the generation of a temperature capable of dissociating the sulphur trioxide formed. In general terms, the process in its entirety, according to one of the claims, "consists in controlling the evolution of sensible heat while oxidising a substance which, upon oxidation, will form sulphur trioxide, by the action of an oxide of nitrogen, by removing the heat evolved from the sphere of formation of the sulphur trioxide by associating therewith substances capable of chemically absorbing heat during reaction, separating the compound containing the chemically-absorbed energy from the sulphur trioxide, discharging the energy therefrom thereafter by chemical action, and producing a substance capable of being re-used as a chemical refrigerant in the further continuance of the process." See also U.S. Pat. 778,099 of 1904; this J., 1905, 90.—E. S.

Alkali-metal oxides; Process of making ——. G. W. Meiser, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 828,759, Aug. 14, 1906.

SEE Fr. Pat. 321,416 of 1902; this J., 1903, 212.—T. F. B.

Hydrosulphite [Hyposulphite] solutions; Method of making ——. P. S. Clarkson, Beverly, N.J., Assignor to H. A. Metz, Brooklyn, N.J. U.S. Pat. 827,420, July 31, 1906.

SULPHUROUS acid is acted upon by a reducing agent, such as zinc, in presence of "an alkali-metal salt of a tribasic acid having an acid reaction to litmus." The use of "trisodium phosphate" is also claimed to produce a hyposulphite solution.—E. S.

Salts of oxy-acids of chlorine [chlorates, e.g.]; [Electrical]. Process of producing ——. A. E. Gibbs, Assignor to The National Electrolytic Co., Niagara Falls, N.Y. U.S. Pat. 827,721, Aug. 7, 1906.

A SOLUTION containing a chloride is electrolysed in a diaphragm cell with a carbon or graphite anode, at a temperature below 40° C. (to avoid disintegration of the anode), and the resulting solution, now containing a hypochlorite, is heated out of contact with the electrodes, to produce a chlorate. A general claim is also made for obtaining a chlorate by treating a hypochlorite solution with a chromic acid compound, applicable in the case described.—E. S.

FRENCH PATENTS.

Carbonic acid; Chemical product for use in obtaining ——. J. A. Ageron and B. J. M. Remy. Fr. Pat. 361,416, April 22, 1905.

A COMPOUND of magnesium sulphate with sodium sulphate or bisulphate is heated with addition of as much concentrated sulphuric acid or sulphuric anhydride as it will absorb, consistently with leaving on cooling a solid product, utilisable, in place of sulphuric or other liquid acid, in liberating carbon dioxide from carbonates.—E. S.

Nitric and sulphuric acids; Process for obtaining concentrated ——, *from nitro-sulphuric acid or nitrous sulphuric acid [in part electrical]*. Der Norske Akt. f. Elektrokemisk Ind., and M. B. F. Halvorsen. Fr. Pat. 363,157, Feb. 13, 1906.

NITROSULPHURIC or nitrous sulphuric acid is dissolved in an excess of concentrated sulphuric acid, a little water is added, and an oxidiser, such as manganese dioxide, lead dioxide, chromic acid or a chromate, in suitable proportion. The nitric acid thus formed is distilled off in iron retorts, and the residue is diluted and electrolysed to recover the oxidiser, thus represented:—

$$Cr_2(SO_4)_3 + 6H_2O = 2CrO_3 + 3H_2SO_4 + 3H_2.$$

The hydrogen formed, is collected; or it may be utilised in electrolytic apparatus in obtaining electrolytic copper from copper salts. Ozone or hydrogen peroxide may be used as the oxidiser, but cannot be regenerated.

—E. S.

Acids [Sulphuric acid]; System of tubes for the concentration of ——. G. Krell. Fr. Pat. 363,604, Feb. 24, 1906.

TUBES intended to be used in the concentration of acids, and in particular of sulphuric acid, are formed of an unattackable material, such as well-tempered white cast iron, in comparatively short pieces. Such pieces are superposed, end to end, and ordinary molten cast iron is run upon them so as to form an exterior coating, making tight joints at the places of junction of the pieces.—E. S.

Nitric acid; Apparatus for oxidising atmospheric nitrogen for the production of ——. O. H. U. Brünler and G. H. Kettler. Fr. Pat. 363,617, Feb. 24, 1906.

SEE Eng. Pat. 5852 of 1906; preceding these.—T. F. B.

Nitric acid or nitrates; Process for utilising atmospheric nitrogen by oxidation, for the production of ——. O. H. U. Brünler and G. H. Kettler. Fr. Pat. 363,618, Feb. 24, 1906.

SEE Eng. Pat. 5901 of 1906; this J., 1906, 811.—T. F. B.

Nitrites; Production of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 363,643, Feb. 26, 1906. Under Int. Conv., Jan. 26, 1906.

THE gases, formed by passing electric discharges through air, are heated to about 300° C. before bringing them into contact with alkali or alkaline-earthy carbonates or hydroxides, to form nitrites, as at that temperature oxidation beyond the state of nitrogen trioxide (N_2O_3) does not take place. Gases containing nitrogen peroxide even, can be utilised in obtaining nitrites by heating them to a sufficiently high temperature before presenting them for absorption, as they thus suffer partial decomposition.

—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 812.)

Glass of low resistivity. C. E. S. Phillips. Brit. Assoc. (Sect. A), York, Aug. 7, 1906; through Electrician, 1906, **57**, 707.

The glass is made by fusing together 32 parts of sodium silicate and 8 parts of calcined borax; an addition of 1·25 parts of Powell's flint glass ensures greater stability, and improves the surface without greatly affecting the conductivity. The density of the glass is 2·490; the resistivity of 1 c.c. at 20° C. is of the order of 10^9 ohms, about one five-hundredth of that of ordinary glass, and changes markedly with the temperature. The glass is somewhat harder than ordinary soda glass; it shows no fluorescence under cathode radiation, is very transparent to X-rays, and opaque to ultra-violet light. When powdered and fused on to clean copper, it adheres well without cracking. It may be cast into plates, but is otherwise not very workable on account of its low fusing-point.—A. G. L.

United States Patent.

Glass; Device for mixing ingredients for making ——, and for feeding them to furnaces. H. M. Brookfield, New York. U.S. Pat. 826,139, July 17, 1906.

The ingredients are placed in separate hoppers, each of which is fitted with a tapering screw-conveyor for impelling the contents toward the discharge orifice. Gearing is provided for working these screws at predetermined speeds, so as to discharge given proportions of the ingredients on to a conveyor. This conveyor carries them to a lifting device, which delivers them into a receiving hopper, fitted in the same way as the others, and discharging into the furnace. All the operations are performed automatically.—C. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 812.)

English Patent.

Cement kilns; Impts. in ——. T. M. Morgan, Longue Pointe, Canada. Eng. Pat. 6946, March 22, 1906.

The kiln is of the rotary type, fitted with circumferential baffle-plates at the mouth, and provided with means for discharging jets of hot air or steam against the baffle-plates, so as to prevent the access of cold air into the kiln. The arrangement of the baffle-plates is such as will impart a revolving motion to the entering air, thus facilitating its admixture with the inflammable gas, and assisting the complete combustion of the latter.—C. S.

United States Patents.

Fireclay retort and brick. E. C. Hegeler, La Salle, Ill. U.S. Pat. 826,032, July 17, 1906.

The retorts or bricks, which are designed for zinc-smelting furnaces, are made of a mixture of burnt and raw fireclay rich in alumina, the burnt portion being heated to a higher temperature than that reached in the zinc-smelting furnace.—C. S.

Refractory material; Manufacture of ——. H. A. D. Collins, Abermellte. U.S. Pat. 826,763, July 24, 1906.

See Eng. Pat. 16,215 of 1902; this J., 1903, 867.—T. F. B.

Cement clinker; Process of burning —— by flame impingement, and apparatus therefor. C. Ellis, White Plains, N.Y. U.S. Pat. 827,517, July 31, 1906.

Into a rotary kiln is delivered from a suitable burner a stream of air, products of combustion, and powdered fuel, at a point above the axis of the kiln, and so as to impinge directly on to a flattened stream of raw material moved past this point. The quantity of inert gas in the blast is regulated, so as to keep the temperature within the limits of safe and effective clinkering.—A. G. L.

French Patents.

Wood; Method of and apparatus for the impregnation and colouring of ——. J. Meyerson. Fr. Pat. 363,072, Feb. 8, 1906.

Trunks of trees of varying diameter are impregnated and coloured with liquids by placing the trunk in a horizontal position with its ends in two cylindrical vessels, one of which, larger in diameter than the other, is fixed, whilst the other can be moved on rails so as to allow for the different lengths of the logs. The joint between the wood and the cylinders is made by rubber (or other elastic) cylindrical envelopes, which are kept tightly pressed against the wood. The impregnating liquid is first forced, under great pressure, from one cylinder to the other through the wood, and then back again, without being at all contaminated by contact with the bark of the tree.—A. G. L.

Wood; Apparatus for impregnating ——, used for constructional work, with antiseptic liquids. H. Altena. Fr. Pat. 363,811, March 3, 1906.

The wood to be impregnated is placed in trucks, which are run on to a stage near the top of a vessel resembling a gas-holder. This vessel can be raised or lowered above a reservoir containing the impregnating liquid by admitting, or withdrawing, compressed air from it. When it is in its lowest position, the charge of wood is completely covered by the liquid. Air is then quickly admitted so as to raise the vessel, and, at the same time, force the liquid into the wood, the operation being repeated if necessary. Special means of regulation are supplied to guard against too rapid an ascent or descent of the vessel.—A. G. L.

Plaster obtained by precipitation; Preparation of ——, for stucco. R. Koepp and Co. Fr. Pat. 363,564, Feb. 23, 1906.

The plaster is obtained chemically by precipitation, burnt as usual, and then subjected to a process of pounding and pugging, by means of which its volume and porosity are diminished, and its specific gravity is increased.

—A. G. L.

Magnesian cement, and method of making the same. W. Jeroch and Deutsche Ferrit-Cement Ges. m.b.H. Fr. Pat. 363,103, Feb. 9, 1906.

The cement is composed of a mixture of calcined magnesia and magnesium sulphate, analogous to Sorel cement; it is claimed to have greater constancy of volume than the latter. Sulphates of bases weaker than magnesia (*e.g.*, of aluminium, zinc) may be added, as also a small quantity of any lead salt, *e.g.*, lead acetate, free from chlorine. A suitable composition is made by mixing 72 parts of magnesium oxide, 23 parts of magnesium sulphate, and 5 parts of lead acetate. The lead salt hardens the mass, and prevents the formation of magnesium sulphate crystals on the surface.—A. G. L.

X.—METALLURGY.

(*Continued from page* 816.)

Gold from cyanide solutions; Electrolytic precipitation of ——. B. Neumann. Z. Elektrochem., 1906, **12**, 569—578; and Electrochem. and Met. Ind., 1906, **4**, 297—302.

For the recovery of gold from dilute cyanide solutions, the author finds that the lead peroxide anodes recommended by Andreoli are unsuitable; the metallic lead beneath the layer of peroxide becomes attacked, forming lead cyanide. Experiments were carried out to determine the current efficiency. When using the ordinary process (lead cathodes and iron anodes), this was found to be exceedingly low, under all practical conditions being far below 1 per cent.

It was subsequently found that graphite electrodes are quite durable in dilute cyanide solutions, and may

be used under certain conditions in place of lead cathodes. If such electrodes be employed, it is possible to directly refine the cathode deposit by employing the electrodes as anodes in a gold chloride solution containing free acid, as is used, for instance, by Wohlwill. By employing this process, the latter part of which can be carried out with very high current efficiencies, the whole difficulty of treating the lead cathodes, containing 2 to 12 per cent. of gold, is overcome, and fine gold of 0·988 purity is obtained instead of bullion of 0·800 to 0·900 purity.
—R. S. H.

Nickel wire; Structural changes in —— at high temperatures. H. C. H. Carpenter. Brit. Assoc., York; through Engineering, 1906, **82**, 222–223.

THE author has investigated the cause of the deterioration and ultimate failure of nickel wire used as the resistance in electrical furnaces of the Heræus type, but with the platinum replaced by nickel. These furnaces stand temperatures of 1200° C. or even 1300° C. well, but ultimately break down, the nickel wire being then found to be very brittle, and to consist of a mass of fibres, which, under the microscope, can be seen to be made up of large crystals. The nickel wire used had the composition: nickel, 98·60; cobalt, trace; iron, 1·22; manganese, 0·16; total, 99·98 per cent. It was made by the Fleitmann process. The author believes the remaining 0·02 per cent. to be dissolved gases, probably nitrogen and carbon monoxide, of a volume greater than that of the nickel they are contained in. From a micrographic study of the changes in the wire, it appears that, under the combined influence of the electric current and the high temperature, these gases are liberated in the nickel, and by alternate heating and cooling are concentrated more and more nearly at the centre of the wire, until their pressure becomes so great that they force a way out between the interstices of the nickel crystals, which have in the meantime been growing larger and larger. The vapour pressure of the nickel itself, which is considerable at 1200° C., probably aids the process. As the author points out, this theory leaves unexplained why platinum wire, which contains no dissolved gases and has no appreciable vapour tension at temperatures up to its fusing-point, does not give results very much better than those afforded by nickel.—A. G. L.

Manganese; Theory of the magnetic alloys of ——. C. E. Guillaume. Bull. Soc. Internat. Electriciens, June, 1906; through Electrician, 1906, **57**, 707.

HEUSLER discovered in 1904 the existence of magnetic properties in alloys containing only manganese, aluminium, and copper. Since then he has shown that the copper acts only as solvent, and that the magnetic properties are due to a manganese-aluminium alloy, $MnAl$; also, that another alloy, Mn_2Sn, is also magnetic. Bismuth, arsenic, antimony, and boron, added to manganese, also yield magnetic alloys, but magnetically feebler than the tin alloy. Aluminium and tin resemble one another in that they give alloys with other metals which melt at a temperature above that of the highest melting constituent. Thus the alloy, Al_2Au, melts at 17° C. above the melting-point of gold; the alloy, AlSb, at about 400° C. above that of antimony; and $NaSn$ at 344° above that of tin. Experiments have also shown that very pure manganese is perceptibly magnetic, but that probably its transformation point is too low for it to exhibit magnetic properties in the ordinary way. The effect of the addition of aluminium and tin to it appears to be to raise the transformation point, and hence to render the magnetic properties evident.—A. G. L.

Manganese and molybdenum; Alloys of ——. Arrivant. Compt. rend., 1906, **143**, 285—287.

BY fusing the metals together, or by reducing mixtures of their oxides with aluminium, the author has obtained a series of alloys containing from 12 to 29 per cent. of molybdenum. They are all well fused and homogeneous, hard, brittle, and non-magnetic; dissolved by acids, and oxidised by fusion with alkali nitrates, bisulphates, or carbonates. Alcoholic solution of acetic acid or of ammonium acetate dissolves manganese from them, leaving the definite compound Mn_6Mo or Mn_4Mo, according to the percentage of manganese originally present.
—J. T. D.

Sulphur; Determination of —— in iron. W. Schulte. XXIII., page 869.

Tin and gold in Federated Malay States. Bd. of Trade J., Aug. 23, 1906. [T.R.]

THE total mining revenue derived from all sources was $9,689,501 for 1905, against $9,249,189 for 1904 an increase in 1905 of $447,312. The export duty on tin amounted to $9,249,627, an increase as compared with 1904 of $434,939; the export duty on tungsten yielded $2213; and the royalty on gold produced only $11,439 as compared with $28,148 in 1904. The output of tin is stated to have been 856,660 pikuls, a decrease, as compared with the output of 1904, of 12,468 pikuls; 548,371 pikuls were exported in the form of tin ore, and 308,289 pikuls as block tin. The market rate was subject to less fluctuation in 1905 than during the preceding year, the highest figure reached having been $88.75 and the lowest $76. The average rate of exchange was higher, and thus the value in sterling of the output amounted to £7,063,407, being at the rate of £138 10s. 5d. a ton. The Acting Senior Warden sees no cause for alarm in the decreased output, and is of opinion that no evidence is forthcoming to show that the stanniferous deposits of the country are nearing exhaustion.

Pig-iron production of United States. Bull. of Amer. Iron and Steel Assoc. [T.R.]

	First half of 1905. Long tons.		First half of 1906. Long tons.
Bessemer pig	5,930,790	..	6,784,619
Low phosphorus pig	77,637	..	114,447
Basic pig	1,966,592	..	2,449,275
Charcoal pig	170,512	..	204,135
Spiegeleisen, ferro-manganese, ferro-phosphorus, Bessemer pig-iron	129,040	..	160,833
Other kinds of pig-iron	2,888,604	..	2,889,592
Total	11,163,175	..	12,602,901

Pig-iron production of Canada. Bull. of Amer. Iron and Steel Assoc. [T.R.]

THE production of pig-iron in Canada in the first half of 1906 amounted to 282,010 tons, against 210,206 tons in the corresponding period of 1905. The production in the first six months of 1906 was the greatest in any half-year in the history of the Dominion, exceeding by 24,213 tons that of the last half of 1905, the next highest half-year. It was also greater than the production of any whole year prior to 1902.

The production of Bessemer pig-iron in the first half of 1906 amounted to 79,051 tons, against 63,785 tons in the first half of 1905. The production of basic pig-iron amounted to 135,298 tons, against 68,378 tons.

Iron ore production of the United States. Bd. of Trade J., Aug. 23, 1906. [T.R.]

ACCORDING to the report of the United States Geological Survey, the year 1905 stands pre-eminent in production of iron ore, with a total for the United States of 42,526,133 long tons, an increase of 20 per cent. over the previous maximum output, 35,554,135 tons in 1902. As compared with the record of the year 1904, the increase in 1905 was 54 per cent.

The following is a summary of the iron ore statistics for the United States for 1905:—

	Tons of 2,240 lb.
Domestic iron ore produced—	
Red hæmatite	37,540,198
Brown hæmatite	2,546,662
Magnetite	2,417,274
Carbonate	21,999
Total	42,526,133
Zinc residuum produced	90,289
Concentrated iron ore produced	755,677
Stocks of iron ore at mines, 31st December, 1905	3,812,281
Stocks of iron ore at lower Lake ports, 31st December, 1905	6,758,511
Production of mines in the Lake Superior region	33,325,018

Steel hardening metals; Production of —— in the United States. Bd. of Trade J., Aug. 23, 1906. [T.R.]

THE United States Geological Survey reports a decline in the total production of steel-hardening metallic ores and concentrates in 1905, as compared with 1904, but the value of the output shows a material increase. Under this head are included all the metals that are used for steel hardening purposes, whether or not this is the main use of the metal. During 1905 the total production of steel hardening metal ores and concentrates amounted to 922 short tons, valued at $288,836, as compared with 1004 tons, valued at $259,620 in 1904. Of the 1905 value, over nine-tenths was due to the production of tungsten ores. There was no production of metallic nickel or of cobalt in 1905, and there was only a very small quantity of nickel and cobalt ore reported sold. All of the chromium ore produced in the United States during 1905 was from California; it amounted to only 25 tons, valued at $375, as compared with the production of 123 tons, valued at $1845, in 1904. There was a considerable increase in the production of tungsten ore during 1905, as compared with that of 1904, and also a general increase in the price paid per ton for the concentrates containing from 60 per cent. and over of tungstic oxide. The total production of the ore was approximately 18,851 tons, from which there was obtained 803 tons of concentrates, valued at $268,676. During 1905 the production of molybdenite and of wulfenite was in excess of the 1904 production of 14½ tons, valued at $2175. The value of the molybdenum ores varies from $230 to $430 per ton, according to the contents. The production of the ores of uranium and vanadium during 1905 amounted to approximately 4 tons, valued at $750. This ore, as shipped, contained 3·06 per cent. of uranium oxide. The total tonnage of ore taken out, as reported to the Survey, is 2081 tons. The production of titanium was somewhat larger than that of 1904, and was entirely from Roselands, Nelson County, Va.

ENGLISH PATENTS.

Heating, smelting, or reducing materials; Process of ——, and means for carrying out the same. E. A. A. Grönwall, Ludvika, Sweden. Eng. Pat. 9799, April 26, 1906. Under Int. Conv., May 8, 1905.

GASES containing carbon dioxide are drawn or forced through glowing carbon in a chamber provided for the purpose. The carbon dioxide is reduced to carbon monoxide, which is then forced into the blast furnace or other apparatus containing the materials to be treated. —J. H. C.

Sand-moulding powder for application to patterns. A. Kemper and F. Damhorst (trading as Kemper and Damhorst), and E. Utke, all of Berlin. Eng. Pat. 14,532, July 14, 1905.

CALCIUM carbide, quicklime, or other powdery mineral material adapted to generate gas or vapour on coming into contact with the moisture of the moulding-sand, is dusted into the mould, or mixed with petroleum or other chemically indifferent liquid, and sprayed into the mould. —J. H. C.

Alloy; A new ——. H. Wilkins, Sheffield. Eng. Pat. 14,733, July 18, 1905.

THE invention relates to a new alloy, stated to be exceedingly ductile, and possessed of great tensile strength, for use as a substitute for German silver, nickel silver, and the like. The proportions of the metals of which the alloy is composed, may be varied, but the following is given as an example: Copper, 50 parts; spelter (zinc), 30; and nickel, 17 parts; with 3 per cent. or less of manganese. Reference is directed to Eng. Pats. 2064 of 1874; and 8137 of 1891 (this J., 1892, 533).—A. S.

Iron or steel; Manufacture of —— in an electric furnace. P. Gredt, Luxembourg. Eng. Pat. 17,178, Aug. 24, 1905.

SEE Fr. Pat. 360,404 of 1905; this J., 1906, 546.—T. F. B.

Steel; Improved process for the manufacture of ——, and apparatus therefor. T. B. MacKenzie and D. Colville and Sons, Ltd., Motherwell, Scotland. Eng. Pat. 21,963, Oct. 28, 1905.

IN the manufacture of steel from molten iron in the open-hearth furnace, a suitable quantity of molten slag from a previous charge is introduced into the furnace, preferably before running in the molten metal from a blast-furnace, in order to avoid unnecessary oxidation of the iron, and also to protect the bottom or bath of the furnace from the corrosive action of the molten metal. The furnace is provided, low down, with an extra door, upon the sill of which a bank of sand or other material is built, to allow of the draining off of surplus slag as the process goes on. —A. S.

Steel; Electric mixing furnace for making ——. Soc. Electro-Métallurgique Française, Froges, France. Eng. Pat. 3004, Feb. 7, 1906. Under Int. Conv., Feb. 11, 1905.

SEE Fr. Pat. 360,072 of 1905; this J., 1906, 485.—T. F. B.

Steel; Process of treating manganese ——. W. Brinton, High Bridge, N.J., U.S.A. Eng. Pat. 3901, Feb. 16. 1906.

SEE U.S. Pat. 812,811 of 1906; this J., 1906, 269.—T. F. B.

Ore concentration; Impts. in ——. H. L. Sulman, London. Eng. Pat. 19,709, Sept. 29, 1905.

THE process claimed is an improvement on that described in Eng. Pat. 7803 of 1905 (see Fr. Pat. 354,960 of 1905; this J., 1905, 1177). The powdered ore is mixed with acidified water, a small proportion (5 per cent. on the weight of ore, or less) of an oily substance such as oleic acid, insufficient to cause the flotation of the metalliferous matter is added, and the mixture is agitated, heated approximately to boiling point until the oil-coated metalliferous matter forms a froth, and then distributed on the surface of a current of water, so that the froth is floated away by the current, while the remaining mineral matter (gangue) sinks.—A. S.

Comminuted materials; Process and apparatus for mechanically discharging —— from receptacles, retorts, or crucibles, whether cold or heated, and in particular the crucibles of zinc-smelting furnaces. Soc. Anon. de Fonderies et Laminoirs de Biache-Saint-Vaast, Paris. Eng. Pat. 98, Jan. 1, 1906. Under Int. Conv., Jan. 5, 1905.

A CURRENT of compressed air, steam, or the like, is conveyed through a hollow rod which is introduced into the retort or crucible. The compressed fluid passes out through two openings in a head-piece fixed on the end of the rod, *viz.*, one jet through an axial opening for the purpose of disintegrating the material in the retort, and a second jet through a peripheral opening so formed that the loosened material is propelled rearwards out of the retort.—A. S.

Aluminium foil; Manufacture of ——. H. H. Lake, London. From Aluminiumwarenfabrik Gontenschwil A.G., Gontenschwil, Switzerland. Eng. Pat. 2146, Jan. 27, 1906.

To obtain flexible aluminium foil of less thickness than

0·1 mm., well-annealed sheet aluminium of about 1 mm. thickness is rolled to 0·3 mm., and the sheet is then folded upon itself, and again rolled between cylinders heated to about 45° C., but in no case to so high a temperature as 100° C. The sheet is then unrolled, and coated with a mixture of "mineral oil soluble in water," and water, and is again folded, and passed through the heated cylinders until the length has again been doubled. One side of the sheet is then coated with the oily solution, folded, and again rolled, and so on, there being always a slight layer of the oily solution between the sheets. When the sheets are reduced to the desired thinness, the group is annealed in the retort of a furnace in which a vacuum has been formed.—E. S.

UNITED STATES PATENTS.

Furnace; Metallurgical ——. R. L. Lloyd and P. Thill, Great Falls, Mont. U.S. Pat. 12,511, July 24, 1906. Re-issue of U.S. Pat. 781,834, Feb. 7, 1905; this J., 1905, 242.

THE hearth of the furnace forms a continuous longitudinally-curved helical path for the ore, from the feed to the discharge end. The hearth is disposed about a vertical axis, and rabble mechanism carrying rabble arms is provided, the rabble arms being capable of conjoint vertical and rotatory reciprocating movement, following the pitch of the helix.—A. G. L.

Furnace; Calcining ——. T. A. Edison, Llewellyn Park, N.J. U.S. Pat. 827,089, July 31, 1906.

SEE Eng. Pat. 4735 of 1902; this J., 1903, 367.—T. F. B.

Furnace; Roasting ——. H. W. Fox, Colorado Springs, Colo. U.S Pat. 827,226 July 31, 1906.

THE invention relates to a roasting furnace, having metallic portions through which rabble-shafts pass. A flue leads from the fireplace to an opening at the top of the ore chamber, and injectors are arranged to project jets of air, or of air and steam, across this opening, in order to deflect the gases from the fireplace away from the parts of the furnace which should not be too highly heated. —A. S.

Furnace; Metallurgical ——. G. H. Benjamin, New York. U.S. Pat. 827,498, July 31, 1906.

THE furnace consists of a heating chamber permanently closed at the top and sides, and of a diameter approximately equal to its vertical height; also of a separable bottom furnished with means for rotating it, and for moving it up and down. A number of hearths can be moved on to and off this bottom by hydraulic power. A gas-producer is placed at the side of the heating chamber, the producer being divided into two sections, each section comprising an air-regenerator, and a producing chamber. By means of suitable ports and passages, the heating chamber can always be filled with flame whatever the position of the bottom.—A. G. L.

Oil from oil-coated fines; Process for distilling off the ——. E. B. Kirby. U.S. Pat. 825,909, 1906. III., page 843.

Precious-metal bearing materials; Process of treating ——. C. W. Merrill, Lead., S.D., U.S.A. U.S. Pat. 825,920, July 17, 1906.

THE crushed material is treated in a container with a cyanogen-bearing solution, then with an alkali or alkaline-earth hypochlorite solution, and finally with a cyanogen-bearing solution, each solution being drained off thoroughly before the next one is applied.—J. H. C.

Lead-bullion; Desilverising ——. A. Raht, San Francisco. U.S. Pat. 826,114 July 17, 1906.

ZINC, followed by sal-ammoniac, is added to the molten bullion, which is then well stirred, and the scum, containing a portion of the lead, is removed.—J. H. C.

Silver; Selective solvent for ——. F. J. Hobson, Guanajuato, Mexico. U.S. Pat. 827,368, July 31, 1906.

CLAIM is made for the use of a 0·05—0·5 per cent. solution of mercurous-potassium cyanide, $KHg(CN)_2$, in presence of alkali, as a solvent for silver when in combination with sulphur.—A. S.

Silver extraction; Process of ——. F. J. Hobson, Guanajuato, Mexico. U.S. Pat. 828,287, Aug. 7, 1906.

ORES containing silver in combination with sulphur are treated with an alkaline solution of mercurous-potassium cyanide of from 0·05 to 0·5 per cent. strength. The mercury sulphide, which precipitates, is removed, and the silver is recovered from the solution.—A. S.

Silver extraction; Process of ——. F. J. Hobson, Guanajuato, Mexico. U.S. Pat. 828,288, Aug. 7, 1906.

THE ore is treated with a solution of potassium cyanide and potassium ferrocyanide in presence of mercuric chloride and an alkali, and the silver is recovered from the solution. —A. S.

Matte; Process of treating ——. J. Savelsberg, Germany. U.S. Pat. 825,983, July 17, 1906.

THE matte is mixed with suitable fluxes, and charged in a suitable apparatus on to a bed of glowing material; an air-blast is then forced through the charge, to sinter it, after which the mass is cooled, broken up, and smelted in a shaft-furnace, thus slagging off the iron, and producing a matte free from iron.—J. H. C.

Brass or other copper alloys; Casting —— into metallic moulds. J. E. Fowler, Assignor to H. H. Beck, Youngstown, Ohio. U.S. Pat. 826,157, July 17, 1906.

THE interior of the mould is treated with a solution of boric acid or other boron compound.—J. H. C.

Flux for extracting metals from ores. A. Gutensohn, Southend. U.S. Pat. 826,568, July 24, 1906.

SEE Eng. Pat. 2619 of 1905; this J., 1906, 319.—T. F. B.

Ores, &c.; Process of sulphatising ——. E. Enke, Kattowitz, Germany. U.S. Pat. 826,925, July 24, 1906.

SEE Ger. Pat. 163,410 of 1904; this J., 1906, 221.—T. F. B.

Ores; Treating ——. F. J. Crane, Denver, Colo. U.S. Pat. 827,620, July 31, 1906.

THE apparatus comprises a tank, an ozone-chamber in the upper portion of the tank, a pump, and an "arrester" or pan with a perforated bottom and a perforated false bottom, disposed above the ozone-chamber, together with the necessary connections. The solution is drawn off from the tank, and returned by the pump through a feed-pipe, which discharges it against the arrester with sufficient impact to effect the pulverisation of the ore. Ozone is introduced into the ozone-chamber, through which the solution passes on its way from the arrester to the tank, and also into the feed-pipe.—A. S.

Zinc and other metals; Process of refining ——. J. Callmann and R. Bormann, Berlin. U.S. Pat. 827,418, July 31, 1906.

SEE Eng. Pat. 3252 of 1906; this J., 1906, 481.—T. F. B.

Composite metals; Process of making ——. T. A. Edison, Llewellyn Park, N.Y. U.S. Pat. 827,717 Aug. 7, 1906.

A SOLUTION containing salts of two or more metals is precipitated, so as to give reducible compounds of the metals in intimate physical admixture, the precipitate then being washed, dried, screened into granules, and subjected to heat in a reducing atmosphere. For example a solution containing nickel sulphate and cobalt sulphate may be precipitated by means of an alkali, and the mixed hydroxides of nickel and cobalt reduced as above.—A. G. L.

Metals; Apparatus for treating, refining, and purifying ——. W. S. Simpson, London, Assignor to the Simpson-Cook Co., Baltimore. U.S. Pat. 828,142, Aug. 7, 1906.

See Fr. Pat. 360,408 of 1905; this J., 1906, 542.—T. F. B.

Iron; Manufacture of ——. O. Thiel, Landstuhl, Germany. U.S. Pat. 828,583, Aug. 14, 1906.

See Fr. Pat. 354,104 of 1905; this J., 1905, 1071.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 818.)

(*A.*)—ELECTRO-CHEMISTRY.

Standard cells; Influence of the size of grain upon behaviour of mercurous sulphate in ——. H. von Steinwehr. Z. Elektrochem., 1906, **12**, 578—581.

THE author is in agreement with Hulett (this J., 1904, 665) that the slight variations in the E.M.F. of the Clark and Weston cells must be ascribed to the mercurous sulphate; but gives evidence against the latter's conclusion that the presence of a basic salt causes the discrepancies. Experiments are described in support of an explanation that the variation in the size of the crystals may lead to values varying by as much as $5{\cdot}0\times10^{-4}$ volt. A method is described for obtaining crystals of the necessary physical constitution, and the view is expressed that, unassisted, the adjustment of the size of crystals occurs too slowly to be of any practical use.—R. S. H.

Nitric acid; Technical production of —— from nitrous gases. J. Klaudy. Z. Elektrochem., 1906, **12**, 545—551.

BY passing an electric discharge through air, some nitric oxide, NO, and nitrogen peroxide, NO_2, are produced. 438 kilos. of nitrogen peroxide or 600 kilos. of nitric acid are obtained under present working conditions by the expenditure of one kilowatt-year of electrical energy, and it is probable that with improved conditions, 900 kilos. of nitric acid might be obtained. If water power be used and the cost of one kilowatt-year be taken at 20*s.*, then the cost of producing 1 kilo. of nitrogen in the form of nitrogen peroxide, is about 2*d.* If water power be replaced by gas or oil engines, the cost is about four times this value.

The best method of utilising the nitrogen peroxide is to bring it at once into chemical action—the manufacture of sulphuric acid by the chamber process or the manufacture of nitric acid and nitrates. In the manufacture of sulphuric acid it is found that the cost of the necessary amount of NO_2 (using a gas engine for generating the electricity) is about one-half the cost of nitre, which has hitherto been used.

Air containing nitrogen peroxide, NO_2, may also be used directly for the manufacture of nitric acid by passing it through water;

$$2NO_2+H_2O=HNO_3+HNO_2.$$
$$3HNO_2=HNO_3+2NO+H_2O.$$

Nitric oxide, NO, is evolved, but being mixed with excess of air it oxidises again to nitrogen peroxide, and is absorbed by water in another vessel. In this way a nitric acid of 50 per cent. strength is produced, and this is concentrated by distillation with sulphuric acid. The total cost of producing 100 kilos. of nitric acid by this method is about 5*s.*, with a sale price of 40*s.*

The production of nitrates for manure would probably be best carried out by using lime as the base.—C. E. F.

Colloids of opposite electric sign; Influence of non-electrolytes on the mutual precipitation of ——. J. L. des Bancels. Compt. rend., 1906, **143**, 174—176.

THE experiments were carried out with the couples colloidal ferric hydroxide and Aniline Blue, colloidal arsenic sulphide and Magdala Red, whilst the non-electrolytes employed were urea, dextrose, saccharose, glycerol, alcohol, formaldehyde, and acetone. It is experimentally shown that, as a rule, a mixture of two colloids of opposite sign, in presence of non-electrolytes, causes precipitation which is complete when the elements are present in proper proportions. Whilst some electrolytes facilitate the mutual precipitation of the two colloids, others, on the contrary, retard it. These latter retarding non-electrolytes are also able to dissociate the resulting precipitate, the retarding and dissociating actions approximately corresponding in intensity.—E. F. A.

Nitric oxide; Determination of —— in air, and some of the reactions involved. Le Blanc. XXIII., page 869.

ENGLISH PATENTS.

Electrodes; Storage Battery ——. T. A. Edison and W. Aylsworth, Orange, N.J. Eng. Pat. 1928, Jan. 25, 1906. Under Int. Conv., April 28, 1905.

THE positive, nickel oxide, electrode consists of a metal grid, on which are supported a number of perforated tubes containing the active material. The tubes are filled, under pressure, with an intimate mixture of nickel hydroxide and conducting flakes of cobalt, or cobalt-nickel alloy; after which the tubes are closed, the flattened ends serving for attachment to the grid.—R. S. H.

Electrode for storage batteries. T. A. Edison, Orange, N.J. Eng. Pat. 1924, Jan. 25, 1906. Under Int. Conv., Nov. 2, 1905.

THE positive electrode comprises a number of tubular perforated pockets about 10 cm. long and 6·5 mm. internal diameter, made of steel of about 0·1 mm. thickness, which has been plated with an alloy of cobalt and nickel, and submitted to a welding temperature in a hydrogen atmosphere before being made into tubes. These tubes are filled with about eight grms. of the active mixture, consisting of relatively large particles of nickel hydroxide and conducting flakes of cobalt or cobalt-nickel alloy, the latter taking the place of graphite, which has been found to deteriorate in use. The above-mentioned materials, mixed with glucose or other sticky material, the proportions being 60 per cent. of nickel hydroxide, and 20 per cent. each of glucose and metal flakes, are stamped into the tubes in very small increments, some 50 or 100 being submitted to a pressure of more than 1400 kilos. per sq. cm. In this way the active particles are deformed, and brought into good contact with the conducting flakes, whilst the glucose assists the adherence of the hydroxide to the metal flakes. Upon subsequently dissolving out the glucose, a network of circulating channels is left, which enables the whole contents of the pockets to be acted upon. Before the ends of the tubes are closed off, metal discs are inserted, which serve to maintain the pressure on the active mass.

—R. S. H.

Arc lamp [Flaming] electrodes, and method of making the same. The British Thomson-Houston Co., Ltd. From Gen. Electric Co. U.S. Pat. 18,484, Sept. 13, 1905. II., page 841.

Filaments for incandescent electric lamps; Manufacture or treatment of ——. H. Zerning. Eng. Pat. 2437, Jan. 31, 1906. II., page 841.

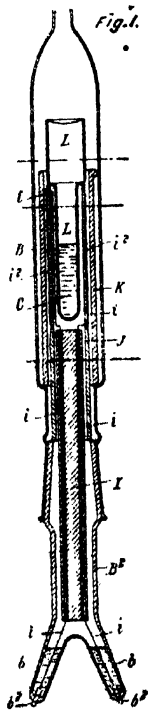
Electric incandescence bodies of difficultly fusible conductive materials; Process for manufacturing ——, *and for uniting such bodies to supply conductors.* H. Kuzel, Eng. Pat. 8057, April 3, 1906. II., page 841.

Bleaching medium; Apparatus for producing a gaseous ——. F. H. Loring, London. Eng. Pat. 22,101, Oct. 30, 1905.

A HOLLOW reciprocating piston forms the chamber in which an electric arc is struck in air. The terminal electrodes, between which the arc plays, are hollow tubes, and are periodically short-circuited by a secondary electrode moving with the piston. Valves are also supplied for the admission of air, and its expulsion after treatment. A felt dust jacket prevents the particles thrown off from the arc from coming into contact with the sliding surfaces of the piston. A special form of O-shaped link is described for connecting the piston to a moving crank, enabling the take-up for wear to be easily carried out.—R. S. H.

Heating matter in high vacua to high temperatures in glass vessels; Apparatus for use in [electrically] ——. F. Soddy, Glasgow. Eng. Pat. 5348, March 5, 1906.

Fig. 1.



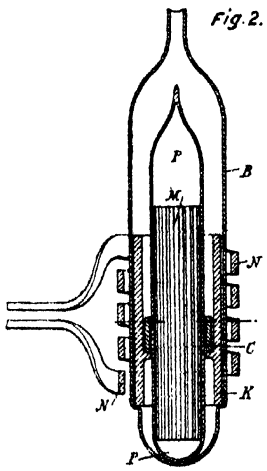


Fig. 2.

THE first form of apparatus is shown in Fig. 1, and consists of an outer glass vacuum vessel, B, into which the lower part, B^2, fits by an air-tight ground joint. The lower part, B^2, has two pockets, *b*, which contain mercury, and into which the platinum electrode wires, b^2, are sealed. The substance, C, which is to be heated, is contained in the porcelain vessel, L, and is heated by the resistance wires, i^2, wound on the porcelain tube, J, and connected to the mercury cups by the wires, *i*, which pass through holes in the porcelain rod, I. The glass vessel, B, is protected from the heat by a porcelain shield tube, K.

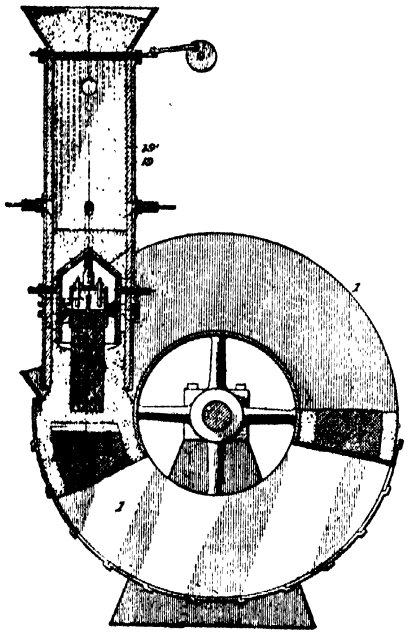
The other form of apparatus, shown in Fig. 2, is used when the body to be heated is a conductor, and can be formed into a ring, C; this is supported on a ledge on the porcelain shield, K, which is placed within the glass vacuum tube, B. A bundle of iron wires or strips, M, contained in the thin glass tube, P, serves as a core, and is inserted in the ring, C, and a helical conductor, N, is placed outside the tube, B. When an alternating current of high periodicity is passed through the helix, N, the arrangement becomes an alternating current transformer, and a secondary current is induced in the ring, C, which forms a single short-circuited secondary, this current serving to heat the body, C.—W. H. C.

UNITED STATES PATENTS

Battery; Alkaline ——. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.Y. U.S. Pat. 827,297, July 31, 1906.

THE battery is provided with an insulator, or support, which is exposed to the action of the electrodes, and an alkaline electrolyte, the insulator being composed of rubber substantially free from active or uncombined sulphur, whereby the formation of sulphides is avoided. —B. N.

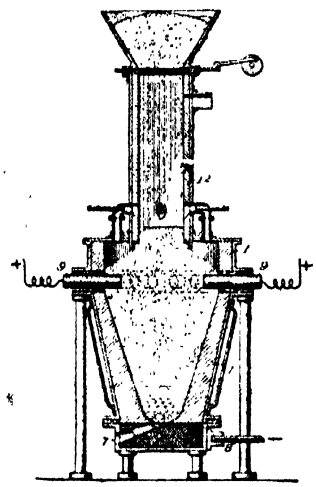
Reducing metallic compounds and producing carbides. E. F. Price, Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 826,742, July 24, 1906.



THE process described, which is covered by twenty-six claims, consists essentially in preheating the charge of an electric furnace, by passing the finely-divided materials through a hot atmosphere, previous to smelting with electric arcs. The heating can be carried out by utilising the carbon monoxide or other gases resulting from the smelting After passing through the preheating chamber, the finely-divided particles are caused to coalesce, and the relatively large body of material is then electrically heated to the temperature required for reaction. The process is described as carried out in a rotating drum furnace, the whole arrangement of apparatus being that described in U.S. Pat. 826,744. (See following abstracts.)—R. S. H.

Reducing compounds and producing carbides. E. F. Price, Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 826,743, July 24, 1906.

THE finely-divided substances, which are to react together, are showered through a preheating chamber, and after being collected to a body of material, are subjected to heating by an electric current passing through a resistance-conductor. By an increase of current density, the heat supplied by the conductor increases along the path of the electric current to a point where the product becomes molten and may be tapped. The preheating may be effected by burning the gases resulting from the electric smelting, and the process can be carried on continuously. The detailed description refers to the electric furnace which is the subject of a separate specification. (See U.S. Pat. 826,745, below.)—R. S. H.



Reducing metallic compounds and producing carbides; Apparatus for ——. E. F. Price, Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 826,744, July 24, 1906.

A PREHEATING chamber, 19, is combined with a rotating drum electric furnace, 1. Means are provided for showering the finely-divided material through the preheating chamber, in which the waste gases (carbon monoxide, &c.), from the electric smelting are burnt by introducing air. The finely-divided particles are collected at the bottom of this chamber into a relatively large body of material, which passes on to the electric furnace, where it is heated by an electric arc. The arc is struck between electrodes, the ends of which are embedded in the material. The electric furnace is capable of rotation so as to withdraw the product from the zone of high temperature as the

reaction proceeds, and fresh quantities of the substances are thus caused to react.—R. S. H.

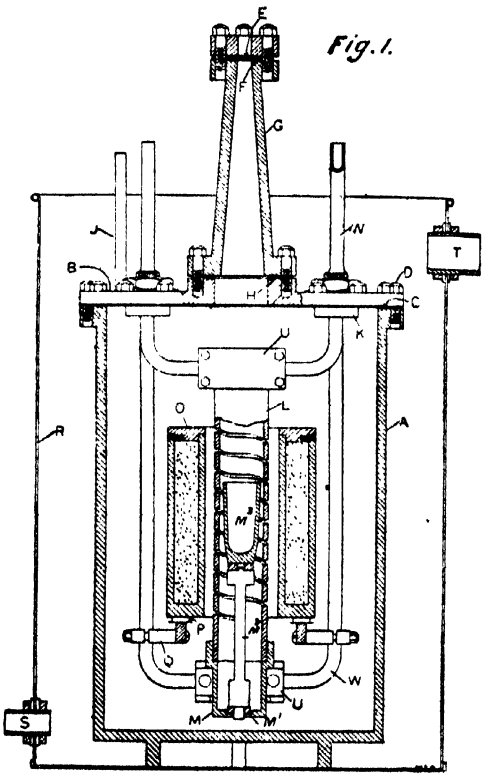
Reducing compounds and producing carbides; Apparatus for ——. E. F. Price, Assignor to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 826,745, July 24, 1906.

The electric resistance furnace, 1, is surmounted by a preheating chamber, 12. Before reaching the electric furnace the reacting materials traverse the preheating chamber, in which the waste gases from the electric furnace are burnt. The electric current enters the furnace by a series of electrodes, 9, which project through the walls, and flows down through the conducting charge to the other electrode, 8. The temperature increases towards the bottom of the furnace, on account of the shape causing increased current density. The conditions are so proportioned that the product is brought into a molten condition, and flows out of the furnace by the tapping hole, 7.—R. S. H.

French Patents.

Incandescence [Electric] lamps; Filaments for ——. A. Just and F. Hanaman. Second Addition, dated Feb. 5, 1906, to Fr. Pat. 347,661, Nov. 4, 1904. II., page 843.

Electric resistance furnace of carbon protected against oxidation. C. Féry and C. Langlet. Fr. Pat. 363,437, Feb. 17, 1906.



The furnace chamber is formed of a tube or muffle of refractory material, and to the walls of this the heating resistance of carbon is applied. The carbon conductor is protected from oxidation by a layer of lampblack or powdered wood charcoal which may have some refractory material added to it. The heating resistance may be formed of carbon rods of various shapes connected in series or parallel according to the voltage of the current available, or may be in the form of a helix worked around the furnace chamber.—R. S. H.

Copper sulphide; Process for making —— for use in the construction of thermo-electric couples. Comp. Thermo-Electrique (Système Hermite). Fr. Pat. 361,420, April 27, 1905.

See Eng. Pat. 11,300 of 1905; this J., 1905, 805.—T. F. B.

(*B.*)—ELECTRO-METALLURGY.

Electric vacuum furnace; The ——. W. C. Arsem. J. Amer. Chem. Soc., 1906, 28, 921—935.

The author points out that previous work *in vacuo* at high temperatures was limited by the temperature at which the vessel, in which the substance experimented with was contained, and which was exposed to external atmospheric pressure, collapsed. The apparatus described obviates this difficulty as only the crucible containing the substance is heated, and both crucible and heater are contained in a vacuum chamber which may be of any suitable material, and is kept at a low temperature. A gun-metal chamber, A, Fig. 1, has a cover, B, fastened down by the cap screws, D, the joint being made tight by a lead gasket, C. The

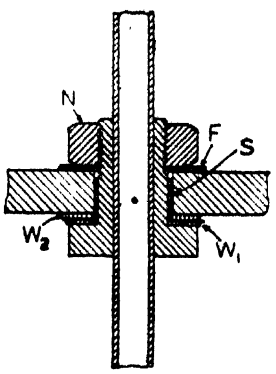


FIG. 2.

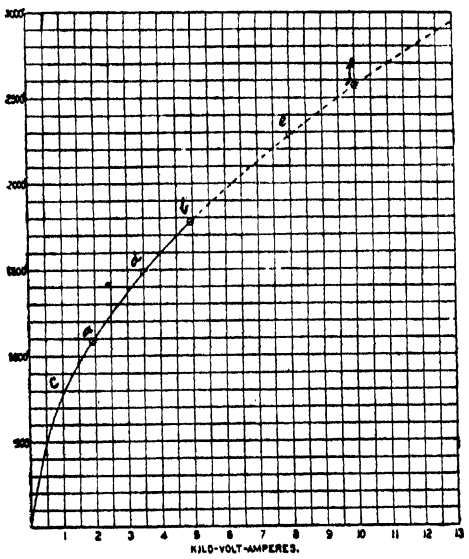

FIG. 3.

vessel, A, stands in a water-jacket, R, provided with inlet and outlet tubes, S, and T, and is raised on four legs to allow the water to circulate underneath the bottom of A. It is provided with a window-tube, G, bolted on to the top, the joint being made tight by a lead washer, H. A window formed of a sheet of white mica, E, 0·005 in. thick, is clamped between two lead washers, F, by a brass cap and screws. The vessel, A, is exhausted through the tube, J, soldered to the top, and the current is led in by the electrodes, W, formed of brass tube, through which water is circulated and which pass through the brass bushings, K. Two lead washers, W_1, and W_2, Fig. 2, separated by a mica washer, are interposed between the cover, B, and the flange of the bushing, which is insulated by the "fibre sleeve," S. The joint is screwed tight by the nut, N, insulated by the "fibre washer," F, and both fibre washers are rendered water-tight by being impregnated with paraffin. The heater, L, is a helix of conducting material, formed preferably of artificial graphite, and is made by sawing a slot in a hollow cylinder of that material. It is supported by copper clamps, U, U, fastened to the electrodes, the lower clamp also serving to support the graphite cup, M, containing the lava insulating ring, M^1, on which the support, M^2, carrying the crucible, M^3, rests. The heater is surrounded by a screen, O, formed of a double-walled cylinder of graphite having the space between the walls filled with powdered graphite. This is supported by the copper arms, *q*, from which it is insulated by the lava buttons, P, and serves to prevent loss of heat by radiation from the outer surface of the heater. The crucibles are formed of any suitable material but magnesia and thorium oxide are very serviceable; the former, however, must have been previously heated strongly to avoid the fracture of the crucible from shrinkage. The crucible containing the substance to be experimented upon is put in position, and the vessel, A, closed and exhausted, the current is then passed, and the behaviour of the substance observed through the mica window; coloured glass is used to protect the eyes at high temperatures. The temperature is estimated from the electrical energy required to produce the observed effect, and the apparatus is calibrated by determining the energy required to melt copper and platinum. The amounts of energy measured in kilo-volt-ampères, *a*, *b*, Fig. 3, corresponding to the melting points of copper and platinum, are plotted on squared paper, and the other points, *c*, *d*, *e*, *f*, are calculated from the formula $y^n = ax$, in which y = the temperature of the crucible above that of the room, x = the energy in kilo-volt-ampères, and n and a constants, the values of which were found to be $n = 1{\cdot}895$ and $a = 285200$. The curve is completed, and the chief error was found to be due to variation in the voltage of the generator, and may amount to 25°, and to 50° for higher temperatures in the neighbourhood of 3000°. It is proposed to verify the temperatures by the use of an optical pyrometer. The number of turns and the width of the slot in the heater must be adjusted so as to avoid arcing and "Edison effect," which destroys the heater. The apparatus has been used for experiments on melting points, the direct production of alloys, and for following gas-producing reactions, and the author consider that it will be useful for the investigation of high temperature phenomena under exact and easily controlled conditions. —W. H. C.

Molybdenum dioxide; Reduction of —— by boron, and the combination of boron with molybdenum. B. du Jassoneix. Compt. rend., 1906, 143, 169—172.

MOLYBDENUM dioxide, mixed with the theoretical quantity of boron, and heated in the electric furnace in a boat of pure magnesium oxide until the mixture begins to melt, is reduced to metallic molybdenum, which is malleable, easily filed, and does not scratch glass. In presence of an excess of boron, the fusion becomes more difficult, a current of 600—700 ampères and 100 volts being required. Compounds of boron and molybdenum containing up to 20 per cent. of boron are prepared in magnesium crucibles, heated in an oven with a current of 400 ampères and 100 volts for two or three minutes after melting; compounds with more boron require a larger current of 500—600 ampères and three or four minutes' fusing. The alloys containing up to 20 per cent. of boron are brittle and have a density decreasing to about six with increasing boron content; the hardest of them scratch quartz. Above 20 per cent. they lose their metallic appearance, and become slate-like and of a bluish-grey hue; their hardness and density diminish. The alloy richest in boron obtained contained 45·6 per cent., and had a density of 3·3. None of the compounds obtained showed a crystalline structure. They are all attacked by fluorine in the cold, and by chlorine above a dull red heat. The powdered compounds are oxidised in the air, and burn in oxygen. Hydrochloric and hydrofluoric acids are without action. Strong sulphuric acid dissolves them on heating; cold dilute nitric acid acts but slowly, though rapidly when heated.—E. F. A.

Gold from cyanide solutions; Electrolytic precipitation of ——. B. Neumann. X., page 848.

ENGLISH PATENT.

Electric furnaces. T. Parker, London. Eng. Pat. 14,884, July 19, 1905.

THE furnace described employs electric resistance and

induction heating, and is intended for refining steel and for smelting nickel and other metals. Electric conductors of carbon, or other material, are embedded in spiral form in the bottom, sides, or top of the furnace casing. On passing an alternating current through these conductors, the molten metal in the furnace is heated by radiation from the incandescent conductors, and also by magnetic and current heating effects produced by induction in the molten metal itself.—R. S. H.

United States Patents.

Iron-oxide scale; Process of electrolytically dissolving ——. C. J. Reed, Philadelphia, Pa. U.S. Pat. 827,179, July 31, 1906.

This invention relates to a process of electrolytically dissolving iron-oxide scale from the surface of a metal, and consists in placing the metal in a solution of sulphuric acid having a density above 1·06, preferably between 1·15 and 1·25. An electric current, of a density not less than 40 ampères per square foot, is passed to the metal as cathode from an anode of lead.—B. N.

Iron sulphate; Process of electrolytically removing scale and producing ——. C. J. Reed, Philadelphia, Pa. U.S. Pat. 827,180, July 31, 1906.

An electric current of sufficient density to remove the scale is passed to the metal as cathode, in an electrolyte consisting of a heated strong aqueous solution of sulphuric acid. A diaphragm is interposed between the cathode and anode, and sulphur dioxide is supplied at the anode. The cathode electrolyte is afterwards removed and cooled, ferrous sulphate being thus precipitated, and the residual solution is returned to the anode compartment of the electrolytic cell.—B. N.

Electro-plating cylindrical articles; Apparatus for ——. R. C. Totten, Pittsburg, Pa. U.S. Pat. 827,478, July 31, 1906.

The article is held by sockets carried on supports which are made to rotate in bearings fixed in the plating tank. The bearings are adjustable towards and from each other, but the supports are incapable of endwise motion, and are fixed opposite each other axially.—R. S. H.

Lead-refining [Electrolytic] apparatus. A. G. Betts, Troy, N.Y. U.S. Pat. 827,702, Aug. 7, 1906.

The electrolytic vat is provided with a "bus-bar," in which is a relatively wide trough-shaped cavity, and the latter has a number of wells of relatively small cross-sectional area, each containing a fluid metal. Several electrodes of unrefined cast lead in the form of plates are supported within the vat, each electrode having a lug overhanging the "bus-bar," and terminal pins, driven into sockets in the lugs, are immersed in the fluid metal in the respective wells. The under surface of each lug is inclined to the plane of the plate, and these inclined surfaces are received on upwardly-presented knife-edges supported on the electrolytic vat.—B. N.

French Patents.

Metal deposits; Formation of brilliant —— by electrolysis. A. Classen. First Addition, dated Feb. 1, 1906 (Under Int. Conv., Feb. 2, 1905), to Fr. Pat. 350,964, Jan 23, 1905.

To the bath for the deposition of the metal, substances belonging to the class of glucosides are added. These may be introduced either singly, or some mixture of different glucosides may be employed. (See this J., 1905, 806.) —B. S. H.

Metals from ores; Electrolytic process for the extraction of ——, *and treatment of copper residues.* L. M. Lafontaine. Fr. Pat. 363,701, Feb. 5, 1906.

As electrolyte, copper sulphate containing free sulphuric acid, hydrogen peroxide, and lampblack, is employed. The electrodes are arranged close together, the anodes consisting of the minerals either agglomerated or merely held in suitable containers. The hydrogen peroxide is intended to prevent iron going into solution, whilst the lampblack "ensures the conductivity of the electrolyte, and assists the molecular deposition of copper at the cathode."—R. S. H.

Tinning of lead; Electro-chemical ——. J. Reczka. Fr. Pat. 363,649, Feb. 27, 1906.

The lead sheet to be coated with tin is first mechanically freed from oxide, and then tinned by an electrolytic process.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 819.)

Acyl groups of esters of polyhydric alcohols; Kinetics of the splitting-off of —— by hydroxyl ions in an aqueous homogeneous system [Theory of saponification]. R. Kremann. Sitzungsber. kaiserl. Akad. Wissensch. in Wien, 1906, **115** [II. *b*], 349—368. Monatsh. Chem., 1906, **27**, 607—626.

In view of the discussion between Lewkowitsch and Balbiano as to whether the saponification of triglycerides proceeds in three stages, with formation of di- and monoglycerides as intermediate products, or in one stage, or, in other words, whether the reaction is bimolecular or polymolecular, the author determined the reaction-constants for the saponification of triacetin, glycol diacetate, and ethyl acetate by sodium hydroxide in aqueous solution at 0° and 19·8° C. The values obtained for the velocity of the reaction were approximately constant when calculated by the aid of the formula for bimolecular reactions, but increased with the duration of the reaction when calculated by the tried formulæ for tri- and quadrimolecular reactions. The results obtained for the reaction-constants show that the rates of saponification of the different acetyl groups differ so little, that the effect is the same as in the case of the saponification of an ester of a monohydric alcohol by an equivalent quantity of alkali. It was probably owing to this cause that Balbiano failed to recognise the formation of intermediate products. The author states that the results of his experiments show that there can no longer be any doubt that the saponification of esters of polyhydric alcohols is a bimolecular and not a polymolecular reaction. (See Lewkowitsch, this J., 1898, 1107; 1899, 1031; 1900, 254.)—A. S.

English Patents.

Grease or oil; Apparatus for rendering or reducing vegetable or animal matter capable of yielding ——. H. J. Haddan, London. From the Edson Reduction Machinery Co., Cleveland, Ohio, U.S.A. Eng. Pat. 22,241, Oct. 31, 1905.

See U.S. Pat. 803,050 of 1905; this J., 1905, 1243.—C.A.M.

Vegetable or animal matter from which oily or greasy matter has been extracted; Process for converting into a marketable product ——. H. J. Haddan, London. From The Edson Reduction Machinery Co., Cleveland, U.S.A. Eng. Pat. 22,242, Oct. 31, 1905.

See U.S. Pat. 803,051 of 1905; this J., 1905, 1243.—T.F.B.

Emulsifying mineral oils; Process for ——, *and for the manufacture of mineral oil soaps.* J. C. Fell, London. From E. Korndörfer, Asch, Bohemia. Eng. Pat. 14,294, July 11, 1905.

The inventor claims the compounding of a stable mixture (soluble in water) of mineral and other oils, by taking the following proportions of the materials: an alkaline-earth sulphoricinoleate, 10—30 parts; olein, oleic acid, or stearin, 10—30; mineral oil, vaseline oil, or spindle oil, 70—30; ammonia (sp. gr. about 0·910), 2½—10 parts. The sulphoricinoleates may be replaced by Turkey Red oil and calcined soda or potash, the proportions of the other ingredients being also subject to modification.

The process consists in treating the alkali compound of a sulphonated oil with any metallic oxide that furnishes a soluble compound with the sulphonated fatty acid, and incorporating the product with oil or fat and ammonia, followed by the mineral oil. The product is soluble in water containing about 3 per cent. (referred to the weight of said product) of calcined soda or potash. The soap claimed by the inventor is prepared by mixing approximately equal parts of strong alkali sulphoricinoleate and oleic acid, adding ammonia till the mixture is clear and alkaline, then adding mineral or tar oil, and a solution of calcined sodium carbonate, the mass being boiled until a clear soap is formed.—C. S.

Colouring matters; Prohibition of the use of injurious —— in Austria-Hungary. Bd. of Trade J., Aug. 23, 1906. [T.R.]

A GOVERNMENT Decree prohibits the use of injurious colouring materials in foodstuffs intended for sale, and the sale of the same. Colouring matters containing antimony, arsenic, barium, lead, cadmium, chrome, copper, mercury, uranium, tin, and zinc, are held to be injurious under this Decree, as well as picric acid and all its compounds, dinitrocresol and its metallic compounds, manchester and naphthalene yellow, orange II., aurantiæ, aurin, gorallin, gamboge, &c.

Further, the above-mentioned injurious colours must not be used in the preparation of eating, drinking, or cooking utensils; cosmetics; toys, picture books and water colours for children. In the finish of carpets, textiles, artificial flowers, leaves, and fruits, and similar articles, for use in connection with clothing, colouring matter must not be used which contains more arsenic than is technically unavoidable. Textiles containing more than 15 mgrms. of antimony per 100 sq. cm. must not be used for clothing purposes. The use of lead compounds in the weighting and dressing of textile goods of all kinds is forbidden, if the same are to be used as clothing.

The Decree comes into effect three months after date of publication, which was on July 20, 1906.

White lead; Apparatus for the manufacture of ——. Union Lead and Oil Co. Fr. Pat. 363,833, March 5, 1906.

CLAIM is made for an apparatus provided with means for the mechanical introduction of the finely-divided lead into the different compartments of the oxidation chamber. There is a frame, moving on rails, and capable of being regulated in height so that the lead falls directly on to the trays, which are then carried on an endless chain or other mechanism into the chamber, where superposed supports are provided to receive them. The feeding device is suspended from upright supports, which can be raised or lowered telescopically, by means of a screw, the said screw and the endless chain being under independent control if required. The oxidation chamber is open at both ends, so that the introduction of one tray expels others in which the conversion of the lead is complete. Several such chambers may be worked in conjunction, with an open space between them, in which is placed a washing apparatus to receive the trays containing the white lead.—C. A. M.

Paint and varnish remover; Non-inflammable ——. C. Ellis. Fr. Pat. 363,506, Feb. 20, 1906.

Linoleum; Treatment of granular composition for ——. Rheinische Linoleumwerke Bedburg Actien-Ges. Fr. Pat. 363,253, Feb. 13, 1906.

THE composition is dusted with a fine vegetable flour, preferably rice or potato flour or other substances with the property of leaving the suppleness of the product intact, whilst themselves imparting a certain agglutinating power. The object of the addition is to destroy the external stickiness of the linoleum composition.—C. A. M.

(*C.*)—INDIA-RUBBER, &c.

Rubber cultivation in Malay States. Bd. of Trade J., Aug. 23, 1906. [T.R.]

THE high price of rubber and the proved suitability of land in the Federated Malay States for its cultivation have led to numerous applications for land, more particularly in Selangor, where almost all the accessible land between the Klang and the Selangor Rivers has been taken up for rubber planting. Next to the coast districts of Selangor, the Sungei Ujong district of the Negri Sembilan appears to be the locality most in favour with rubber prospectors. The area alienated for the planting of Para rubber is some 100,000 acres, of which about 38,000 acres have already been planted. Most of the Para rubber trees of the age of five years or more have been planted 200 to the acre; some estates have as many as 300 to the acre. On the more recent clearings the average is probably 175 to the

acre. The number of trees of all ages in the Federated Malay States may perhaps be put at six to seven millions. The rubber production of 1905 is estimated to have been 300,000 lb.

Depilatory agents; The action of ——. E. Stiasny. Gerber, 1906, **32**, 200—202, 214—216, and 228—231.

THE usual depilatory agents such as lime, alkalis, sodium sulphide, &c., besides removing the hair also increase the weight and volume of the hide or skin, and more or less improve its elasticity. The author records the results of experiments undertaken with a view of ascertaining the course of the action of different depilatory solutions. The action is shown to be dependent on the concentration of the solution, but even in the same concentration, different alkaline solutions have very varying effects. For instance, when N/20 solutions are employed, sodium and barium hydroxides make the hide very elastic and increase the weight, but have little, if any, depilatory action, whilst calcium hydroxide and ammonia, which completely remove the hair, give comparatively little increase in the weight, and do not improve the elasticity. Although the depilatory action is dependent on the concentration of hydroxyl ions in the solutions, such is not the case with the increase of weight of the hide, and the elasticity diminishes as the depilatory action increases. Ammonia, however, differs considerably in its action from sodium hydroxide, in that, even in dilute solution, it completely removes the hair. Taking each alkali separately, the actual amount absorbed by the hide is proportional to the concentration of the solution, but from N/20 solutions more than twice as much lime is absorbed as soda. The quantity of hide substance going into solution is also proportional to the strength of the alkali solution, and sodium hydroxide and ammonia dissolve about twice as much as calcium and barium hydroxides.—W. P. S.

Tannery effluents; Biological purification of ——. W. Eitner. Gerber, 1906, **32**, 199—200, 213—214, and 227—228.

ALTHOUGH the effluents from tanning and leather works vary considerably in their composition, the biological treatment will, in most cases, effect their purification. It is necessary, should free acids be present, to treat the effluent with precipitants in a settling tank before it passes to the decomposition tank and filters. By careful construction of the plant and good supervision, effluents may be obtained which are free from tannin, colour, turbidity, and odour, and which develop no trace of odour even when kept in closed vessels for a considerable period of time. Effluents containing soluble arsenical compounds cannot be treated by the biological process. —W. P. S.

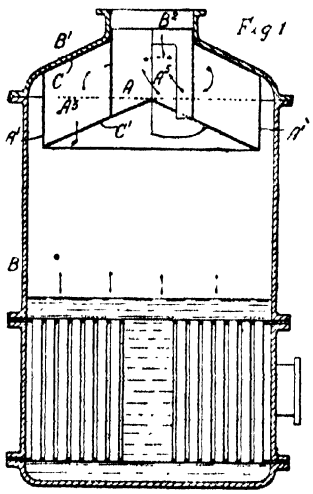
Beetroots; High polarising substances in ——. K. C. Neumann. Z. Zuckerind. Böhmen, 1906, **30** [10, 11], 536—545.

IT has been frequently asked whether the high dextrorotatory polarisation of beetroot juice is due to sugar only, or whether such constituents as raffinose and complicated polysaccharides (dextrans) are present. The question usually arises when the output of sugar in the factory does not correspond with what would be expected from the polarisation of the beet, the undetermined losses appearing abnormally high. The past season in Bohemia was marked by beet products of high polarisation, so that in a factory making white sugar (cubes, granulated, &c.), and employing a saccharate process (separation), the runnings of the second product showed not only a high polarisation, but, as compared with the previous year, which was a normal one, a large quantity of raffinose



(up to 3 per cent.), or other substance of similar character the presence of which was indicated by inversion. Beets from different districts of Bohemia showed differences between direct polarisation and sugar as determined by the Clerget inversion of 0·35 to 0·47 per cent. when the juice of fully ripe beets polarised 18·9 to 22·3 per cent. The analyses were carried out so as to obviate errors due to the volume of lead precipitate during clarification, or quantity of acid used for inversion. The cause of the observed differences is, therefore, scarcely to be sought in the analytical procedure, but in the special character of the beetroots during the campaign 1905-6.—L. J. DE W.

English Patents.

Evaporators for sugar. D. Stewart and Co., and T. Wishart, Glasgow. Eng. Pat. 16,269, Aug. 10, 1905.

Claim is made for an evaporator fitted with an entrainment preventer, which consists of an annular or approximately annular chamber, AA^1, closed at top and bottom, fitted in the dome or upper end, B^1, of the evaporator, B, and composed of cylindrical outer and inner shells, of which the outer one, A^1, has a segment cut out of it at A^2 (Fig. 2), so as to present an opening at A^3, between the inner and outer shells, outside a plate, A^4, which joins them, and extends tangentially from the inner shell to the outer one. On the inside of A^4, an opening is made at A^5 in the inner shell, so that a free passage is formed for the vapour from the evaporator entering the annular chamber round the inner shell, A, and passing thence through the opening, A^5, upwards through an outlet formed by a continuation of the inner shell, extending into the outlet funnel, B^2, at the top of the evaporator. The upper part of the entrainment chamber is formed by a plate, C, in contact with the domed top, B^1, of the evaporator, or the said dome may serve as the top plate of the chamber whose bottom or lower side is closed by a plate, C^1, of conical formation, having one or more draining holes, *c*, around the lowest edge. The path of the vapour is indicated by arrows; any particles of liquor carried by the vapour are caused by centrifugal force to strike the outer shell, A^1, whence they descend and drop through the orifices, *c*.—T. H. P.

Sugar juices; Purification of ——. C. H. Bertels, Brussels. Eng. Pat. 17,554, Aug. 30, 1905.

Claim is made for a process for the purification of sugar juices by means of hydrofluosilicic acid, according to which the sugar juice at about 22° B. is cooled, and the acid solution at about 32° B. is added in the requisite quantity, whilst the liquid is stirred, and after the precipitate has formed and settled, the clear liquid is decanted, whereby a liquid is obtained which is easy to filter; the neutralisation of the liquid is also rendered possible, and the recovery of the hydrofluosilicic acid is easy. This recovery of the acid from the alkali fluosilicate formed is carried out by adding an equivalent quantity of sulphuric acid and for every 140 parts of the latter, 35 parts of silica, and then applying heat as in the ordinary process for the manufacture of hydrofluosilicic acid; the alkalis present are transformed into sulphates which furnish a valuable manure. If the addition of silica be omitted in the recovery process, hydrofluoric acid is obtained.—T. H. P.

Sugar; Mechanical "blueing" apparatus for use in the treatment of ——. R. König, Brussels. Eng. Pat. 22,435, Nov. 2, 1905.

The apparatus consists of a closed tank of given capacity, having a vertical central pipe, the upper end of which is closed by a ball-valve. At the bottom of the tank are two openings, one under and in connection with the central tube, and the other a short distance from it. These openings lead to a three-way cock, by turning which the tank may be filled with steam; on again turning the cock, the steam is directed through a pipe to a tangential distributor containing the sugar to be treated; the steam supply being cut off from the tank, condensation takes place, and a supply of "blueing liquid" is drawn into the tank. On once again turning the cock, steam is admitted up the central pipe of the tank, and its contents forced out into the distributor.—W. P. S.

Sugar and similar materials; Centrifugal machines for clarifying and washing ——. C. Schüller, Grevenbroich, Germany. Eng. Pat. 10,278, May 2, 1906.

In the centrifugal machine described, there is arranged a series of moulds and clarifying chambers, the latter being pivoted by means of links to a frame in such a manner that, by moving the frame, the chambers may be pressed against or moved away from the moulds. The clarifying or washing liquid is supplied from a tank, arranged on the frame, to the chambers, and, as the lower portions are narrow, no accumulation of the liquids can take place at the said lower parts. In this way the layers of the material contained in the moulds are subjected to a uniform clarifying or washing.—W. P. S.

French Patents.

Liquids [Sugar solutions, &c.]; Evaporation, concentration, distillation, and drying of ——. A. Montupet and L. Jannin. First Addition, dated Feb. 7, 1906, to Fr. Pat. 339,177, Nov. 21, 1903. I., page 840.

Dextrin; Process and apparatus for adding moisture to ——. W. H. Uhland, G.m.b.H. Fr. Pat. 363,623, Feb. 26, 1906.

The dry dextrin falls down a vertical tower, the sides of which are fitted with inclined plates. In its zig-zag course down the tower, the dextrin encounters a current of moist air introduced at the bottom of the tower.—W.P.S.

Beer yeast; Comparative studies on three species of top-fermentation ——. P. Regensburger. Z. ges. Brauw., 1906, **29**, 430—433 and 440—442.

The author has submitted three races of top-fermentation beer yeasts to a close botanical study similar to that made by Will on four races of bottom yeasts (this J., 1904, 450). To a certain extent the microscopic form of the cells served to differentiate one race from another, but there was no specific difference between the cells of these yeasts and those of the bottom yeasts. Differences were recorded as regards the resistance of these three races to high temperatures, the time required to start fermentation, the character of the yeasty head, the intensity of spore formation, and the time elapsing before spores were formed in relation to variations in the temperature. As regards film formation, the fundamental observations recorded by Will for the bottom-fermentation yeasts, hold good for the top-fermentation yeasts. As a rule, the long chains of sausage-shaped cells belonging to the first generation of film cells were far more numerous in these top-fermentation yeasts than in Will's bottom yeasts, and the production of films was more intense. One of these yeasts was distinguished by its very slight tendency to form a yeast ring. The films on old cultures were mostly composed of resting cells [chlamydospores] differing from those of bottom yeasts only in their relative poverty in glycogen. The colonies developed from single cells on solid media belonged to the irregular types (Will's types 2 and 3), which are rarely observed in bottom yeasts, most of which develop according to the regular type 1 (mulberry type). With large sowings, the yeasts showed differences amongst themselves as regards the appearance of the colonies and the formation of streamers. The old colonies also differed in the time of formation as well as in the proportions of the constituent cells of the later generations. The chief difference between colonies from large sowings of these top yeasts and Will's bottom yeasts, was the relatively early appearance of resting cells amongst the delicate, elongated cells of the streamers, and the production of cells of the second generation from these resting cells. In the case of bottom yeast, Will never observed these cells amongst the streamers; he only observed them on the surface of the central portion of the colonies.

The author concludes that different races exist amongst the top-fermentation beer yeasts just as much as amongst the bottom beer yeasts, and that these races are capable of being differentiated by careful observations of their morphology and modes of development under various conditions, as well as by their physiological properties. The analogy between the life-history of the top yeasts and that of the bottom yeasts is complete. The only differences between the two classes are the greater rapidity and intensity of growth, budding, spore formation, and film development shown by the top yeasts as a rule. In addition, the spar-like growth of the budding chains, which also shows itself in the form of the colonies from single cells on solid media, and the non-secretion of the enzyme melibiase, are, with few exceptions, characteristic of the top-fermentation races.—J. F. B.

Yeast; Plasmolysis and turgor-regulation of ——. N. H. Swellengrebel. Centralbl. Bakt. Abth. 2, 1905, **14**, 374—388 and 481—492. Woch. f. Brau., 1906, **23**, 300—302.

When yeast is subjected to the osmotic pressure of a highly concentrated solution, the cells undergo plasmolysis. Very pronounced plasmolysis promptly occurs when the yeast is placed in undiluted glycerol. The behaviour of the protoplasm under these circumstances is variable; sometimes it shrinks entirely away from the cell-wall; at other times it remains attached thereto at various points; the vacuole becomes flattened and sometimes divided. With less concentrated solutions the effects are less marked, and a diminishing range of effects is observed as the concentration is lowered, until a minimum limit of concentration is reached at which no plasmolysis occurs. With dilute solutions of glycerol this minimum limit of concentration cannot be accurately determined in the case of old cells, but in young cells, with buds still adhering, an indication of incipient plasmolysis is afforded by the appearance of a narrow zone of separation on either side of the dividing wall between the mother and the daughter protoplasms. Yeast is sensitive to sudden changes in the osmotic pressure. If yeast be grown in a highly concentrated medium, and then be brought suddenly into water, many of the cells burst, whilst others develop elongated swellings with extremely thin walls. The plasma extruded by the burst cells, brings about the agglutination of the others. When the cells are killed by plasmolysis, the vacuole retains its vitality for a longer period than any other portion of the cell-contents. The minimum limit of pressure required to produce visible plasmolysis is taken as a measure of the turgor pressure of the yeast; it is the resultant of the osmotic pressure, the distension pressure of the plasma, and the surface tension. In the case of a young culture of yeast in Fischer's solution, the turgor pressure was equivalent to that of a solution of 0·24 grm.-mol. of sodium chloride per litre, = 8·4 atmospheres; that of pressed yeast straight from the factory was 0·4 grm.-mol. of sodium chloride, = 14 atmospheres; and that of yeast grown in grape-must was 0·6 grm.-mol. of sodium chloride, = 21 atmospheres. The yeast responds to changes in its surroundings by changes in its turgor pressure, but on the whole it is not so sensitive as the mould fungi are. Temperature and aëration are without effect. The turgor varies according to the nature of the carbonaceous and nitrogenous nutrients supplied to the yeast; the transference of yeast from a nutrient medium to a non-nutrient medium of the same osmotic pressure causes a considerable fall in its turgor pressure. Substances vary in their plasmolytic effects according to whether they penetrate the cell wall or not. A substance is described as "non-intrameate," *i.e.*, non-penetrating, if it cause visible plasmolysis at concentrations isosmotic with 0·25—0·33 grm.-mol. of sodium chloride per litre. Non-intrameate substances exert their full osmotic pressure on the yeast, but in the case of partially intrameate substances the osmotic pressure is partly balanced by the penetration of the dissolved substance through the membrane; such substances require higher concentrations for plasmolysis. Most of the salts of the alkali metals are non-intrameate, the sugars are intrameate; ethyl alcohol penetrates easily, glycerol with difficulty, and mannitol not at all; chloral hydrate is non-intrameate.

Yeast may be cultivated in solutions of increasing osmotic pressures up to 2·5 grm.-mols. of sodium chloride per litre.

Cultivation of the yeast in solutions of high osmotic pressure induces a corresponding rise in the turgor pressure; yeast can be grown in a 60 per cent. solution of cane sugar as soon as its turgor pressure has regulated itself to the high concentration. Conversely the turgor pressure is lowered by transference from a concentrated medium to a dilute one, provided the change is not so sudden as to burst the cells.—J. F. B.

Yeast; Behaviour of butyric and allied acids in presence of ——. T. Bokorny. Allgem. Brauer.- u. Hopfen.-Zeit., 1906; Z. Spiritusind., 1906, **29**, 292.

Ten grms. of yeast are killed by between 0·05 and 0·1 grm. of normal butyric acid, though a 0·05 per cent. solution of the acid does not prevent reproduction. Lactic acid of 2 per cent. strength will stop reproduction. In the case of isovaleric acid, 0·2 grm. does not kill 10 grms. of pressed yeast; the lethal dose is in excess of this figure. The lethal dose of normal valeric acid for 10 grms. of pressed yeast is between 0·25 and 0·5 grm., but nearer the former, a strength of 0·1 per cent. being sufficient if the quantity be large enough. For the same weight of yeast, 0·25 grm. of caproic acid is insufficient to produce fatal results; isocaproic acid is still less poisonous. The author also finds that the ortho compounds of the nitrotoluenes and nitrobenzaldehydes are more poisonous to vegetable and animal cells than the para compounds, the converse being the case with the toluidines.—C. S.

Beer, bottled; Bacterial flora of ——. *I. Pseudomonas cerevisiae.* F. Fuhrmann. Centralbl. Bakt. Abth. 2, 1906, 16, 309; Z. ges. Brau., 1906, 29, 466.

Pseudomonas cerevisiae, grown at 22° C. on neutral nutrient gelatin, agar-agar, boiled egg albumin, neutral nutrient broth, or peptone water, forms motile rods that show no tendency to unite to form chains. A tuft of 4—6 undulating flagellæ is present on one pole of the cell. Though 22° C. is the optimum temperature, growth proceeds at 0° C., and a thin film is formed on agar-agar at 35° C. In neutral broth, a greyish-white skin is formed, together with general haze and a whitish sediment, the liquid gradually turning pale yellow. Growth proceeds on similar lines, though less decidedly, in peptone water.

At higher temperatures, long rods, uniting to long filaments, are formed. The optimum alkalinity for the organism in broth is equivalent to a content of 1 per cent. of $N/1$ sodium hydroxide solution. The smallest trace of acetic acid prevents all growth. No gas is liberated in saccharine broth (grape sugar); no indole can be detected in cultures in peptone water or broth. The organism is facultatively anaërobic. Growth occurs in Mayer's mineral nutrient solution II., with special sources of carbon and nitrogen. On agar-agar the organism will stand heating to 60° C. for an hour, 1½ hours being necessary for sterilisation, but half an hour is sufficient in beer containing 4—5 per cent. (by vol.) of alcohol. In nutrient broth the addition of 1 per cent. of ethyl alcohol prevents growth. The bacterium grows badly in sterilised beer, and produces slight haze. In mineral nutrient solution containing 1 per cent. of ammonium chloride, the short rods grow longer, and generally unite in pairs, one member developing a pear-shaped terminal enlargement. The chains also throw out laterally a number of small warty excrescences, swelling up into globular bubbles that undergo constriction. These growths, when transferred to fresh nutrient solution, develop long, large, and also very small, short, motile cells. Large and small globules are also found, lying side by side, with a fine connecting filament between them, analogous to the formation of zygospores in higher fungi.—C. S.

Acetic ferment; Composition of an ——. E. Aliaire. Compt. rend., 1906, 143, 176—178

The bacteria were collected from the surface of about 2000 litres of liquid, which had been fermented with a technically pure culture, washed with water and alcohol, and dried; only about 5 grms. were obtained. The alcohol extracted 1·56 per cent. of fatty matter from the bacteria; this was composed, to the extent of from 50—60 per cent. of lecithin. The product free from fat gave 6·9 per cent. of nitrogen and 5·9 per cent. of ash, which consisted chiefly of phosphoric acid, potassium, calcium, magnesium, sodium, and iron oxides, and also contained 1·66 per cent. of copper and some silica. The author considers that the high proportion of copper and iron present, indicate that these metals play an important part in the phenomena of acetification.—E. F. A.

Fermentable matter in grain; Determination of ——. Boidin and de Lavallée. XXIII., page 870.

Fruit juices; Determination of malic acid and other fixed acids in ——. W. Mestrezat. XXIII., page 870.

Alcohol production in France. Times, Aug. 17, 1906. [T.R.]

According to statistics published in the "Journal des Débats," there were 24,038 "professional" distillers and 753,865 private distillers in France in 1905. The total production of alcohol, which was 2,181,362 hectolitres (about 48 million galls.) in 1904, rose to 2,530,116 hectolitres (about 55½ million galls.) in 1905, an increase of 348,754 hectolitres.

English Patents.

Beer, and other liquids; Apparatus for chilling and carbonating ——. E. A. Attuck, The Farringdon Works, and H. Pontifex and Sons, Ltd., all of London. Eng. Pat. 17,622, Aug. 31, 1905.

The apparatus consists of an open brine tank provided with a refrigerating coil; in this tank is placed a vertical closed cylinder, the ends of which are preferably concave, and the sides corrugated horizontally. The closed vessel is charged with carbon dioxide, and the beer then passed in at the top through a spraying device, so that it flows down the corrugated sides of the vessel. When the beer has filled the vessel to a certain height, the operation of drawing it off is commenced; this is done by means of a pipe at the bottom of the cylinder, by which the beer is conducted to the filter and bottling apparatus. Carbon dioxide may be pumped into the bottom of the closed vessel to obtain a higher carbonation of the beer.—W. P. S.

Filtering and washing apparatus, more particularly for use in brewing. A. Jacobs, Brussels, and L. Desenfans, Lille. Eng. Pat. 19,730, Sept. 29, 1905.

Claim is made for an improved apparatus for filtering worts and extraction of mash residues for brewery purposes, in which the bottom of the apparatus is provided with channels serving both for running off the worts and for the introduction of the washing water through the filter plates covered with filter-cloths into the mash residues, and in which a space, provided above the filter-plates serves as the mixing chamber in which the residues and the washing water are intimately mixed, for the purpose of securing the complete exhaustion of the said residues.—T. H. P.

Brewing; Process of ——. H. C. Lee, London. Eng. Pat. 26,274, Dec. 16, 1905.

Unmalted grain, previously gelatinised, is treated in a separate vessel, and at a higher temperature than the initial mash heat, with a portion of the wort obtained by mashing malt. Both the grain and the malt are treated preferably in a finely-ground condition. The two worts, after being drawn off, can then be treated separately with hops in the ordinary manner, or may be mixed together in any desired proportion for such treatment. The mash tun and the grain vessel are provided with the usual agitating, heating, and cooling arrangements.—W. P. S.

Carbohydrates in general; Process of treating [*Rendering soluble*] —— *principally for grain distillation.* A. Boidin, Seclin, France. Eng. Pat. 16,589, Aug. 15, 1905.

In order to remove alkali and magnesium phosphates, which have a retarding action on the solution of the starch, and thus to facilitate the boiling and solution of carbohydrates, chiefly in the distillation of grain, the obstructing phosphates are removed by washing or treatment with alkali or with salts of the heavy metals. The grain may also be treated by the addition of a quantity of mineral or organic acid not more than sufficient to convert the major part of the phosphates into the condition of monobasic phosphates. The solutions thus obtained contain only soluble starch and traces of glucose, the object being to manufacture soluble starch in a favourable condition for diastatic saccharification. It is stated that the final process of boiling (the process following that of removing the phosphates, &c.), now only needs to continue from three-quarters of an hour to an hour.—W. P. S.

United States Patent.

Malt house and apparatus. W. P. Rice, Chicago. U.S. Pat. 826,886, July 24, 1906.

See Eng. Pat. 14,103 of 1905; this J., 1905, 1318.—T. F. B.

French Patent.

Brandy from Algerian grapes; Process for making ——. E. A. Barbet. Fr. Pat. 361,428, May 1, 1905.

The juice obtained from the grapes is saturated with chalk, and then heated to a temperature of 65° to 75° C. in order to coagulate the albuminous matters present. A little ox-blood and milk of lime may also be added to ensure complete clarification, and the solution is then filtered. If the juice be slightly alkaline it is neutralised by the addition of phosphoric acid before filtering. Any excess of lime is thus precipitated. The clear juice is now

oncentrated, *in vacuo*, to a syrup of about 30° to 35° B. This is filtered through a mechanical filter and then through animal charcoal. It is then run into casks for exportation, or for brandy production.—W. P. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 825.)

(*A.*)—FOODS.

Sodium sulphite recoverable from food products; The amount of —— as a basis for the determination of the amount originally present. C. D. Holley. J. Amer. Chem. Soc., 1906, **28**, 993—997.

THE results of a number of experiments are given, in which known amounts of sodium sulphite were added to meats, and the quantity of sulphurous acid recoverable determined after allowing the meats to stand for varying lengths of time. When the treated meat has stood for 36 hours, this quantity is shown to be approximately one-fourth of the amount added originally. From the results of analyses of sausage meats, &c., bought at butchers' shops, it is seen that the amount of sulphites mixed with meats to preserve them is much larger than is generally supposed. One sample yielded 0·361 per cent. of sodium sulphite (calculated from the sulphurous acid obtained), showing that about 1·44 per cent. had been added originally. The amount of unoxidised sulphite remaining in fried meats (sausages) is also about one-fourth of the quantity added. In the case of dried fruits which have been bleached with sulphurous acid, free or combined, the amount remaining unoxidised in the fruit is large, averaging 0·124 per cent. in 14 samples examined. From one sample as much as 0·226 per cent. was recovered, calculated as sodium sulphite.—W. P. S.

Butter; The Polenske method for the detection of cocoanut oil in ——. S. Rideal and H. G. Harrison. XXIII., page 870.

ENGLISH PATENTS.

Food; Sterilisation of articles of ——. C. C. L. G. Budde, Copenhagen. Eng. Pat. 15,304, July 25, 1905.

THE process consists in adding hydrogen peroxide with hydroxylamine, or hydrazine, to the food to be preserved, the quantity of hydrogen peroxide added being in excess of that required to decompose the hydroxylamine. An example is given in the case of milk:—0·15 grm. of hydrazine hydrate and 1·35 grms. of hydrogen peroxide are added to each litre of milk to be sterilised. The milk is then heated to from 50° to 55° C. for about three hours, when it will be found to be completely sterile." By using larger quantities of the preservatives, the heating may be omitted.—W. P. S.

Drying foodstuffs of vegetable origin; Process for ——. F. Zündel-Donati, Schirmensee, Switzerland. Eng. Pat. 15,597, July 29, 1905.

SEE Fr. Pat. 356,335 of 1905; this J., 1905, 1319.—T. F. B.

UNITED STATES PATENT.

Food products and method of making the same; Vegetable and other ——. J. E. Bloom, New York. U.S. Pat. 825,888, July 17, 1906.

THE food is prepared from seed meals, such as cornmeal, by adding to the same such proportions of olein, palmitin, and stearin as will cause the fatty content of the product to have the approximate composition of human fat. See also U.S. Pats. 782,820 and 782,821 of 1905; this J., 1905, 341.)—W. P. S.

FRENCH PATENT.

Animal tissues or mixtures thereof with other substances; Process of preserving ——, and products obtained thereby. J. R. Hatmaker. Fr. Pat. 363,679, Feb. 28, 1906.

SEE Eng. Pat. 4351 of 1905; this J., 1906, 332.—T. F. B.

(*B.*)—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

Water; Apparatus for purifying —— by distillation. W. Clark, London. From The American Water Purifying Co., Philadelphia. Eng. Pat. 16,177A, Aug. 8, 1905.

SEE Fr. Pat. 356,762 of 1905; this J., 1905, 1319.—T. F. B.

Water, or other liquids; Apparatus for purifying ——. E. Stephenson, London. Eng. Pat. 25,016, Dec. 2, 1905.

UPON the spindle of the hydraulic measurer, described in Eng. Pat. 3731 of 1886, a toothed wheel is secured and gears into another toothed wheel fixed to the spindle of the concave quadrant, described in Eng. Pat. 13,069 of 1901. To some convenient part of the apparatus two brackets are fixed, carrying screw bolts, by the setting of which the supply of the quantity of the reagent to the water can be regulated as required.—W. P. S.

UNITED STATES PATENTS.

Water; Process of purifying ——. A. Brown, Lorain, Ohio, Assignor to American Wire Co., New Jersey. U.S. Pat. 825,637, July 10, 1906.

FERROUS sulphate, copper sulphate, and calcium hydroxide are added to the water, and the precipitate formed allowed to settle, a germicidal layer being thus produced through which the water is filtered. The amount of copper sulphate added is relatively small.—W. P. S.

Sewage; Clearing vat for ——. B. Schmidt, Dresden, Germany. U.S. Pat. 828,515, Aug. 14, 1906.

SEE Eng. Pat. 24,402 of 1905; this J., 1906, 231.—T. F. B.

FRENCH PATENTS.

Water; Process for the purification of ——. G. Lambert. Fr. Pat. 361,435, May 3, 1905.

THE water is treated with potassium permanganate, and then with a quantity of manganese sulphate sufficient to decompose the excess of permanganate. The precipitation is rendered more complete and is hastened by the subsequent addition of a small quantity of sodium carbonate. After settling, the water may be either decanted or filtered from the precipitate.—W. P. S.

Water, sewage, &c.; Apparatus for the purification of ——. H. Riensch. Second Addition, dated Jan. 23, 1906, to Fr. Pat. 314,450, Sept. 24, 1901. (See this J., 1902, 1064.)

MEANS are provided by which the sedimentary matters, separated from the water by the apparatus described in the original patent, are carried off by lateral conduits, whilst the floating substances are removed from the revolving plate by means of brushes which work automatically.—W. P. S.

Water; Process and plant for the purification of ——. Grondel Frères. Fr. Pat. 363,073, Feb. 8, 1906. Under Int. Conv., Dec. 9, 1905.

THE water to be purified is led into a conduit where it is mixed with chemical reagents, such as lime, sodium carbonate, and aluminium sulphate, solutions of which are contained in tanks placed above the conduit. The treated water then passes into a second conduit extending across the top of a series of cemented settling tanks; over each tank is an opening in the conduit which allows the water to fall into

a vertical pipe reaching to the bottom of the tank, and provided with perforated radiating arms. The water, as it falls down the vertical pipe, carries with it a certain volume of air, which aids in stirring up a quantity of mud at the bottom of the tank, resulting from a previous treatment of a tankful of water. The openings leading to the vertical tubes are provided with valves. When sedimentation has taken place, the water is decanted from the tanks by means of floating pipes which collect the water at the surface, and carry it off through the bottom of the tanks. The réagent tanks are provided with water and steam supplies, and an arrangement of travelling buckets allows the sediment to be removed from the tanks when required.—W. P. S.

Effluents; Method for the distribution of septic tank ——, for fertilising purposes. C. Harper. Fr. Pat. 363,297, Feb. 15, 1906.

The effluent from the septic tank is led into a covered chamber and flows, or is pumped, thence into ordinary drain pipes set in cultivated ground at a convenient depth below the surface, so that the effluent at once comes into proximity with the roots of plants growing on the ground. If needed, a disinfecting tank may be placed between the septic tank and the closed chamber.—W. P. S.

(C.)—DISINFECTANTS.

English Patent.

Bacteria in the blood and tissues; Apparatus for destroying ——, by the influence of carbon monoxide. B. H. Thwaite, London. Eng. Pat. 18,492, Sept. 13, 1905.

To destroy tubercule bacilli and other organisms in the blood, the patient is treated with an atmosphere containing about 0·4 per cent. by volume of carbon monoxide, the treatment being regulated so as to be well within the safety limit. The carbon monoxide generator consists of a lined metallic furnace, in which a column of anthracite coal or charcoal is maintained at a certain height, and means for forcing or drawing a regulated quantity of air through the same. The gas issuing from the furnace is passed through filters and a cooling apparatus, and is then collected in a balanced gas-holder. Part of the air-supply is directed into a second holder, and both the volume of air admitted to the furnace and that leaving the second holder are regulated by valves actuated by the rising of the carbon monoxide gas-holder. The air leaving the second gas-holder is mixed with a portion of the carbon monoxide, and the mixed gases are conducted to a chamber from which they are drawn off for use. Finely-divided carbon, produced by the incomplete combustion of a hydrocarbon gas, may be introduced into the mixture of carbon monoxide and air.—W. P. S.

French Patent.

Antiseptic; A new —— [from petroleum], and method of making the same. C. Trocquenet. Fr. Pat. 362,990, Feb. 5, 1906.

Fossil shells are heated to redness, then mixed with a specially prepared petroleum oil, and the mixture distilled at a high temperature. The distillate forms the antiseptic claimed. The above-mentioned petroleum oil is obtained by emulsifying 6 litres of liquid paraffin with 1 litre of water containing from 60 to 80 grms. of potassium chloride, calcium phosphate, and calcium malate. The emulsion is heated, strained through metallic gauze while boiling, and finally filtered.—W. P. S.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page 825.*)

Fibres and fibrous materials for papermaking; Philippine ——. G. F. Richmond. Philipp. J. Sci., 1906, 1, 433—462.

The author has carried out experiments on a semi-industrial scale in order to test the suitability of various Philippine fibre-materials for papermaking.

Abacá [Manila hemp], *Musa textilis.*—The cordage fibres are only taken in thin ribbons from the outer surface layers of the petioles. After these ribbons have been taken, the bulk of the stems, the outer sheaths, and the cut ends, (representing the greater portion of the plant) remain as a fertiliser on the land. For fertilising purposes it is sufficient if the juice of the plant (90 per cent.) be returned to the soil, and the solid waste is capable of yielding good papermaking fibres. This waste, after drying, was boiled under pressure with 25 per cent. of caustic soda, and yielded 20 per cent. of good paper-pulp. This semi-fibrous waste is quite distinct from the wholly fibrous waste obtained in stripping and cleaning the cordage fibres. This latter waste (machine-stripped) when boiled with 25—30 per cent. of caustic soda, yielded 30—33 per cent. of pulp. Hand-stripped waste yielded 38—42 per cent. of pulp. This class of pulp consumes 12—14 per cent. of bleaching powder, with a loss of 6—7 per cent. of fibre substance.

Plantain, M. sapientium, var. *paradisiaca.*—The banana and plantain fibres are inferior to abaca for cordage purposes, but yield a superior pulp, and the resolution of the fibres is more easily effected. The author has only experimented with the cleaned textile filaments obtained from the outer strips of the plantain. These yielded 65 per cent. of pulp when boiled with 20 per cent. of caustic soda.

Maguey [Sisal hemp], *Agave cantula.* The filaments are used for cordage, but the waste from the stripping and cleaning processes is available for paper-making. This waste, when boiled with lime without pressure, yields a brown half-stuff with a loss of about 30 per cent. of its weight. The product is not a paper-pulp, but merely a concentrated form of the raw material. When boiled with 10 per cent. of caustic soda, calculated on the original waste, it yields 31 per cent. of good pulp, also calculated on the original material. The crude waste can be boiled with lime under pressure, yielding 55 per cent. of pulp for coarse brown papers. With 25 per cent. of caustic soda, the crude waste gave 35 per cent. of good paper pulp.

Grasses.—Two important grasses are available in the Philippines for paper-making.

Cogon (*Imperata exaltata*) is broad-leaved, and grows in dry districts, attaining a height of 2—4 ft. It contains 50 per cent. of cellulose on the dry substance as compared with esparto with 55 per cent. Under industrial conditions this grass yields 44—47 per cent. of pulp with 15—10 per cent. of caustic soda. Lime is not suitable for the preparation of good pulp. The pulp consumed 15 per cent. of bleach with a loss of 5—6 per cent. in weight.

Talahib (*Saccharum spontaneum*) is a coarse-jointed grass growing to a height of 6—10 ft.; it springs in tufts from stout underground root-stalks, and thrives best in low-lying moist districts. If allowed to become too dry before cutting, the nodes harden and are not easily resolved. Boiled with 12·5 per cent. of caustic soda, it yielded 45·5 per cent. of pulp, which bleached easily with a consumption of 5·7 per cent. of bleach and a loss of only 2·2 per cent.

Dimensions of Philippine paper fibres.

	Length mm.			Diameter mm.		
	Max.	Aver.	Min.	Max.	Aver.	Min.
Abacá	6·00	3·93	2·45	0·021	0·017	—
Plantain	7·30	5·49	4·15	0·026	0·020	0·013
Maguey	4·93	2·38	1·00	0·026	0·018	0·015
Cogon grass	1·82	0·99	0·46	0·021	0·011	0·005
Talahib grass	2·82	1·89	0·89	0·020	0·015	0·012

—J. F. B.

Parchment paper; Action of weak alkaline solutions on ——. C. Bartsch. Papier-Zeit., 1906, 31, 2547.

The author has found that slightly alkaline solutions have a deleterious effect on the mechanical properties of parchment papers. Strips of the papers were steeped for 24 hours in 1 per cent. solutions of sodium carbonate, caustic soda, and potash soap; they were then removed, and

dried in the air, without washing; finally they were thoroughly washed and dried. Determinations of the tensile strength of the strips, as compared with that of similar strips treated with water only, showed diminutions in the breaking length and breaking elongation, amounting in extreme cases to 21 per cent. and 44 per cent. respectively. —J. F. B.

Celluloid. W. Will. Z. angew. Chem., 1906, 32, 1377—1387.

The author has made investigations with a number of specimens of celluloid and celluloid articles, as well as with celluloid prepared by himself from stabilised nitrocellulose, for the purpose of determining its liability to ignition and explosion. From the experimental results obtained, he concludes that celluloid of good quality is a comparatively insensitive substance. Shocks, blows, friction, electric sparks, or heating to 100° C. neither ignite it nor cause it to explode. Some samples, however, decompose or ignite at such temperatures as may readily obtain in the neighbourhood of electric arc lamps or other sources of heat. This defectiveness may be due either to the use of unstable nitrocellulose in making the celluloid, or to the employment of too high a temperature in moulding or pressing it into the desired shapes. The author suggests that it may be necessary, in order to ensure the production of stable articles, to adopt in the celluloid industry the precautionary methods prevailing in the manufacture of nitro-explosives. Celluloid which is liable to decompose at a comparatively low temperature, may be detected by the following test: 0·1 grm., in small pieces, is placed in a strong, lightly-corked test-tube, and immersed in an oil-bath previously heated to 100° C. The temperature of the bath is kept uniform by means of a stirrer, and is raised steadily at the rate of 5° per minute. The point at which the sample fumes off is observed. Samples which do not decompose below 160° C., when thus tested, may, in the author's opinion, be regarded as satisfactory; instances are quoted in which the decomposition point was as low as 124° C. Compact celluloid burns without explosion, but celluloid dust can be ignited by powerful electric sparks, and can explode when ignited. The explosions which sometimes occur during fires in which celluloid goods are involved, are most probably due to the gases given off by the burning material. Thus the author finds that when celluloid is heated in absence of air, or with an insufficient supply of air, the gases evolved are rich in carbon monoxide, methane, and hydrogen, and when mixed with widely varying proportions of air, form explosive mixtures. Burned with insufficient air, celluloid also evolves much nitric oxide, and a little hydrocyanic acid. In fire-extinguishing operations, the presence of these three poisonous gases must not be lost sight of.—H. B.

Incandescence mantles; New process of manufacturing ——, in which copper-cellulose is used as fabric. W. Bruno. II., page 840.

English Patents.

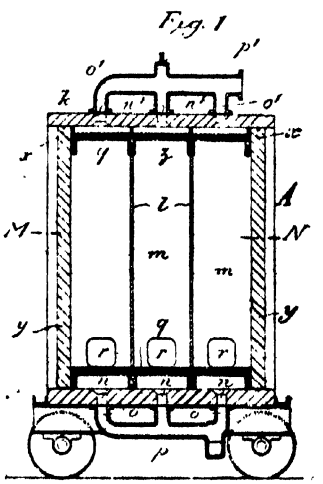
Peat-moss; Method and apparatus for manufacture of half-stuff for millboard and paper from ——. G. D. Beresford, London. Eng. Pat. 23,748, Nov. 17, 1905.

Sods of freshly-cut peat moss are disintegrated in a "devil," between fixed and rapidly revolving teeth. The material is then delivered into a store tank, in which it is immersed in water. Thence it passes by means of conveyors into a series of washing tanks, and is conducted through the whole series against a counter-current of water introduced at the discharge end. The washing tanks are provided with endless bands carrying stirring rakes and screens, which push the moss along, with a combing and disentangling action, over the perforated bottoms of the tanks. A discharge-conveyor at the end of each tank lifts the moss into the next tank, and, in the process, the moss is passed between pairs of horizontal rollers placed between each pair of tanks.—J. F. B.

Paper; Means for applying size to ——. J. Lockett and W. J. Baker. Eng. Pat. 15,417, July 27, 1905.

Size is applied in the form of a fine stream to the web of paper in the course of its manufacture, the point of application being at the delivery side of the couch-rolls, or at some point on the "wet felt." The size is maintained at a constant level in a trough of V-shaped section, arranged over the upper roll of what are known as the "Duxbury" rollers. At the point of the V there is an orifice extending the whole length of the trough, which can be opened or closed to any desired extent. A strip of felt extends from this orifice, and conveys a thin layer of size to the upper "Duxbury" roll, which in its turn transfers it to the web of paper.—J. F. B.

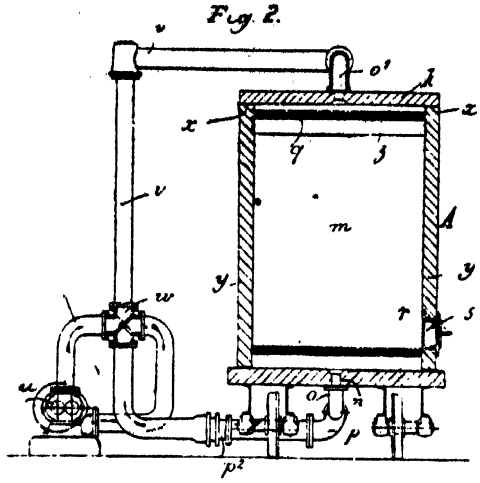
Absorbent materials, textiles, paper, or other lamellar materials; Improved method for treating or impregnating —— with resins, fatty acids, or the like. H. O. Brandt. Eng. Pat. 23,787, 1905. V., page 845.



Paper, pasteboard, cardboard, and the like; Process of producing highly brilliant transparent coatings on ——. Kraemer und van Elsberg, G. m. b. H., and G. Kraemer, Cologne, Germany. Eng. Pat. 26,201, Dec. 16, 1905.

Brilliant, transparent coatings are produced by applying to paper, card, &c., a suitable collodion to which has been added a chlorhydrin and also a derivative of an aromatic sulphonic acid as specified in Eng. Pat. 25,434 of 1899 (this J., 1901, 62), the paper being subsequently pressed for a time with hot, polished surfaces. 50 to 60 parts of dichlorhydrin and 250 to 350 parts of *p*-toluenesulphochloride are added to a solution of 100 parts of nitrocellulose in 450 parts of alcohol and 350 parts of acetone, and the mixture is applied to the paper.—T. F. B.

Paper and card; Apparatus for impregnating —— in a paper-making machine during its manufacture. F. Dobler, Paris. Eng. Pat. 4304, Feb. 21, 1906.



See Fr. Pat. 359,930 of 1905; this J., 1906, 441.—T. F. B.

Cellulose from vegetable fibres; Manufacture of ——. Sir W. Mather, Manchester. Eng. Pat. 8960, April 28, 1905.

Cellulose is prepared from raw vegetable fibrous materials by the chlorination process in an apparatus, working in a continuous manner, in which all the successive operations are conducted without handling the material from start to finish. These operations consist of boiling with dilute alkali, washing, cooling, and partially drying the material by the action of a current of air at a reduced pressure, chlorinating the moist fibre, washing out the by-products of chlorination, boiling the chlorinated fibre

Fig. 2.

with alkali, and finally washing the cellulose. The fibrous raw material is suitably packed in " vehicles " of resistant material which can be wheeled from one treating apparatus to another, and which are divided internally by vertical perforated partitions into a number of cells, *m*, (see Figs.). The vehicles are placed in connection with fixed circulatory systems providing the reagents, junctions being effected at the top and bottom by the pipes, *v*, p^1, *p*, with orifices leading to the separate cells. The liquid or gaseous reagent—alkali, water, air, or chlorine gas—is then circulated by means of a pump, *u*, in a vertical direction through the perforated distributing sieves, *q*, and through the masses of fibre in the cells, the course of the current being reversed from time to time. By providing a " battery " of circulating systems for each operation, the whole cycle of treatments can be effected with the complete utilisation of the chemicals employed. —J. F. B.

Cellulose derivatives and process of making the same. G. W. Miles, Belmont, Mass., U.S.A. Eng. Pat. 19,330, Sept. 25, 1905.

See Fr. Pat. 358,079 of 1905; this J., 1906, 195.—T. F. B.

Cellulose substitute. F. and A. van den Bosch, and O. Müller, Cologne, Germany. Eng. Pat. 3211, Feb. 9, 1906. Under Int. Conv., Feb. 10, 1905.

The non-fibrous constituents of the cotton-seed husk are utilised in addition to the fibrous constituents as a substitute for cellulose in its various applications. The non-fibrous constituents are isolated by a series of treatments comprising a treatment by a boiling dilute alkali solution, which extracts a useful red colouring matter, followed by treatments with bleaching powder solution, dilute acids, and boiling alkali. The process may be varied by oxidation treatments with permanganates followed by sulphurous acid. (See also this J., 1906, 775.)—J. F. B.

United States Patent.

Paper web; Apparatus for smoothing the —— in paper-making machines. C. Tittel, Gratwein, Austria-Hungary. U.S. Pat. 828,149, Aug. 7, 1906.

See Eng. Pat. 2795 of 1906; this J., 1906, 775.—T. F. B.

French Patents.

Strainers for paper-pulp. P. Billon. Fr. Pat. 363,279, Feb. 14, 1906.

In flat-strainers of the type in which the vibration is communicated to the central axis of the plate-cradle, the rods supporting the cradle on the cam-wheels are generally cast in a single piece. In this invention, these rods consist of two portions, the upper portion of the rod resting on the lower portion by means of an articulated cup-joint. The cup which forms the upper end of the lower portion of the rod can be raised or lowered on a screw-thread for adjusting the height of the cradle in the trough. It is claimed that the articulated joint mitigates the shock, and prevents the breakages which often occur in the usual form of rod.—J. F. B.

Celluloid; Manufacture of a substance resembling ——. C. Claessen. Fr. Pat. 363,090, Feb. 8, 1906.

A substance resembling celluloid is manufactured from nitrocellulose by replacing the whole or a portion of the camphor usually employed by benzylidene di- or mono-acetoacetic ester, prepared by the condensation of benzaldehyde, with acetoacetic ester in presence of an organic base. The nitrocellulose, 5 kilos., is treated with a solution of 3·5 kilos. of the benzylidene compound in 10 litres of alcohol, and the mass is rolled at a temperature between 60° and 90° C.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 827.)

Phaseolus lunatus; Cyanogenetic constituents of ——. Kohn-Abrest. Compt. rend., 1906, **142**, 182—184.

The author has obtained from *Pois de Java, Haricots de Java, &c.*, a colourless crystalline cyanogenetic glucoside, melting at 134°—136° C., which on crystallisation from ethyl acetate is resolved into three substances, melting at 132°—134° C., 125°—129° C., and 118°—119° C. respectively, and containing 8·3, 8·6, and 7·3 per cent. of hydrocyanic acid. They are all hydrolysed by an enzyme contained in the Java beans, which is destroyed by boiling with water, but has its activity only partially impaired by being heated at 78° C., or at 122° C. for two hours. This enzyme differs from the emulsin of bitter almonds in that its action on hydrogen peroxide is more vigorous, whilst it only feebly decomposes amygdalin. Emulsin is without action on the *Pois de Java* glucosides. The author disputes the presence of acetone in his glucosides, and finds that they yield small quantities of alcohol when hydrolysed. Analysis proves that they possess the formulæ $C_{10}H_{19}O_6N$ and $C_9H_{25}O_6N$, whereas Dunstan and Henry found $C_{10}H_{17}O_6N$; the author accordingly regards them as mixtures, and considers that a large variety of cyanogenetic glucosides occurs in *Phaseolus lunatus*.—E. F. A.

Oil from the fruit of Pittosporum undulatum; Constituents of the essential ——. F. B. Power and F. Tutin. Chem. Soc. Trans., 1906, **89**, 1083—1092.

The authors examined a freshly-distilled specimen of oil from the fruit of *Pittosporum undulatum*, Ventenat, a tree indigenous to south-eastern Australia, where it is known as " Native Laurel " and " Mock Orange "; 220 kilos. of the fruit yielded 960 grms. of oil having a pale yellow colour and an odour resembling that of orange oil. After being dried with anhydrous sodium sulphate, and filtered, the oil had the sp. gr. 0·8615 at 15°/15° C., and an optical rotation of +74° 4′ in a 100 mm. tube; it was insoluble in ten times its volume of 70 per cent. alcohol. Twenty grms. of the oil required 0·2 c.c. of N/2 alcoholic solution of potassium hydroxide for the neutralisation of the free acids, and 4 c.c. for the hydrolysis of the esters present. The oil was treated with dilute sulphuric acid, then extracted several times with a 5 per cent. solution of potassium hydroxide, and afterwards washed with water, dried with anhydrous sodium sulphate, and distilled under 60 mm. pressure. Fractionation of the distillate failed to reveal the presence of an olefinic or other unstable terpene. The whole of the oil distilling above 190° C. at the ordinary pressure, was hydrolysed with alcoholic potash, and the residual oil, after being washed and dried, was distilled under 60 mm. pressure, whereby a small quantity of non-volatile resinous matter was removed. The hydrolysed oil, together with the portion which had previously been separated under diminished pressure, was fractionated at the ordinary

pressure. The fractions distilling below 165° C. and between 165° and 169° C., consisted of a mixture of *d*-pinene and *d*-limonene, whilst that distilling between 173° and 180° C., representing by far the largest portion of the oil, consisted almost entirely of *d*-limonene. The fractions 205°—215° C. and 215°—225° C. consisted mainly of an oxygenated compound, and after oxidation with potassium bichromate and sulphuric acid, yielded a semicarbazone, $C_{10}H_{17}ON_3$, melting at 174° C. The oxygenated compound present in the oil, is probably an alcohol of the formula, $C_9H_{16}O$. From the fraction, 255°—270° C. an optically inactive sesquiterpene was isolated, boiling at 263°—264° C., sp. gr. 0·9100 at 15°/15° C., $n_D^{20°} = 1·5030$. The acids present in the oil in the form of esters consist mainly of valeric acid together with very small amounts of acids of a lower and a higher molecular weight. The constituents of the oil identified up to the present are:—About 4 per cent. of *d*-pinene, about 75 per cent. of *d*-limonene, small quantities of esters of valeric, formic, and other acids, about 15 per cent. of an optically inactive sesquiterpene, very small quantities of palmitic acid and an undetermined phenol, and apparently, a trace of salicylic acid.—A. S.

Hydrogen peroxide; Preservation of medicinal —— by means of sodium chloride or calcium chloride. Allain. J. Pharm. Chim., 1906, **24**, 162.

Sodium chloride and calcium chloride in the proportion of 1 per cent. are found to be more efficient as preservatives of medicinal hydrogen peroxide than phosphoric or sulphuric acid in the proportion of 1 per mille, or 95 per cent. alcohol, 2 to 3 per cent. The rate of decomposition with the two first-named salts is at least ten times slower, under like conditions, than with the other preservatives. They are, moreover, much less objectionable, from the therapeutic point of view.—J. O. B.

Colloidal precipitates; Washing of ——. J. Duclaux. Compt. rend., 1906, **143**, 296—298.

It is maintained by some that colloidal precipitates cannot be completely washed, because they form with the saline substances accompanying them, compounds not decomposed by water. Nicolardot and Wyrouboff, for example, consider that the compound $Fe_2(OH)_5Cl$ or Fe_2Cl_6, limits the possibility of removing chloride from colloidal ferric hydroxide. The author combats this. He has obtained by dialysis a ferric hydroxide containing less than one-third of the amount of chloride implied by the above formula, and sees no reason why the removal of chloride should not be carried further. It is, however, impossible practically to remove the whole, because of the extreme slowness of the process.—J. T. D.

Sodium-mercuric iodide and barium-mercuric iodide. A. Duboin. Compt. rend., 1906, **143**, 313—314.

These two compound iodides may be prepared as follows: Sodium iodide and mercuric iodide are dissolved alternately in a small quantity of water until no more of the substances are taken up (see this J., 1905, 988). After standing for some months in a dry atmosphere, the solution at first deposits mercuric iodide, and afterwards, flat crystals which have a composition corresponding with the formula, $2NaI,HgI_2,4H_2O$. The crystals are extremely deliquescent, and their sp. gr. is about 3 at a temperature of 0° C. The author has obtained a new barium-mercuric iodide by evaporating in a dry atmosphere during the hot summer months, a solution containing mercuric iodide and barium iodide, and having the composition, barium, 12·45; mercury, 22·53; iodine, 51·68; and water, 13·34 per cent. Large flat crystals were deposited. They had the composition, $BaI_2,HgI_2,5H_2O$, and a sp. gr. of about 4 at 0° C.—W. P. S.

English Patents.

Iodine preparations [from fatty acids]; Manufacture of new ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 17,874, Aug. 28, 1905.

See Fr. Pat. 362,370 of 1906; this J., 1906, 714.—T. F. B.

Eserine; Manufacture of a new salt of ——. G. B. Ellis, London. From E. Merck, Darmstadt, Germany. Eng. Pat. 26,818, Dec. 22, 1905.

See Ger. Pat. 166,310 of 1905; this J., 1906, 443.—T. F. B.

Polychloramidines and alkyl derivatives thereof; Manufacture of ——. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 10,228, May 1, 1906.

Claim is made for the production of polychloramidines by the reduction of nitro-acylaminopolychlorbenzene, or an alkyl derivative thereof, the nitro-grouping being in the ortho position to the amino-grouping. If ring formation does not take place during the reduction, the product may be heated, or treated with a dehydrating agent. Polychloramidines produced in this way can be subsequently alkylated by the usual methods. The methods of preparation of the following are described. Ethenyltrichloramidine, m.pt. 285° C.; methenyltrichloramidine, m.pt. 303°—304° C.; methylmethenyltrichloramidine, m.pt. 159°—160° C.; ethylethenyltrichloramidine, m.pt. 116°—117° C.; ethenyltetrachloramidine; ethylethenyltetrachloramidine, m.pt. 149° C.; benzylethenyltetrachloramidine, m.pt. 176°—177° C.; benzenyltrichloramidine, m.pt. 268°—269° C.; methylethenyltrichloramidine.—(See this J., 1906, 608).

—F. Sheon.

Thorium; Process of obtaining ——, applicable for making incandescent lamp filaments. The British Thomson-Houston Co., Ltd., London. From the General Electric Co. of Schenectady, New York. Eng. Pat. 14,972, July 20, 1905.

A compound of thorium, in particular thorium dioxide, is heated in the vapour of sulphur monochloride to bright redness, to form thorium tetrachloride (thus, $ThO_2 + 2S_2Cl_2 = SO_2 + 3S + ThCl_4$), which remains behind when the sulphur and sulphur dioxide pass off. It is recommended to repeat the process on the powdered fixed residue, to eliminate impurities. The thorium tetrachloride, which is in small white hygroscopic crystals, is heated, preferably mixed with a certain proportion of potassium chloride, in a steel crucible, with an excess of sodium, in the vacuum furnace described in U.S. Pat. 785,535 of 1905 (this J., 1905, 446), and in Eng. Pat. 20,809 of 1904 (this J., 1905, 976). The gas formed during the heating is pumped out as it is formed. Towards the end of the reaction, the temperature is raised sufficiently to distil off the excess of alkali metal. The thorium remaining after the product is washed repeatedly with hot water, and is treated with hot dilute nitric acid to remove thorium hydroxide. The thorium is then washed successively with hot water, alcohol, and acetone, and is dried.

—E. S.

United States Patents.

Alkamine ester [of aminobenzoic acids]. F. Stolz and G. Korndörfer, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pats. 828,070 and 828,071, Aug. 7, 1906.

See Eng. Pat. 17,162 of 1905; this J., 1906, 607.—T. F. B.

Alkamines [Aminoalcohols]; Process of making ——. E. Fourneau, Paris. U.S. Pat. 828,846, Aug. 14, 1906.

See Fr. Pat. 339,131 of 1903; this J., 1905, 43.—T. F. B.

French Patents.

Amino-alcohols and their derivatives; Preparation of ——. J. Rousset, France. Fr. Pat. 361,471, May 13, 1905.

This patent relates to the production of α- or β-substituted amino tertiary alcohols of the fatty series. The preparation of dimethylaminodiphenylethanol $(CH_3)_2N.CH_2.C(C_6H_5)_2OH$ is given as a type. According to the method of Grignard, dimethylglycollic ethyl ester is treated with magnesium-phenyl bromide. On hydro-

lysing, a good yield of the amino-alcohol is obtained. All the bases formed by this method are soluble in water, and crystallise in long brilliant needles; they reduce permanganate and solutions of silver. α-Ethyldimethyl-aminobutanol, $\alpha(CH_3)_2N.CH_2.C(C_2H_5)_2OH$, boils at 57° C. at 23 mm.; the hydrochloride of its benzoyl derivative melts at 175° C. Claim is made for the process and the new products obtained by its means.—F. Sndn.

Hexamethylenetetramine borates; Preparation of ——. Act.-Ges. f. Anilinfabr., Germany. Fr. Pat. 363,764, March 1, 1906.

Claim is made for the production of hexamethylenetetramine borates by the action of an alcoholic or aqueous solution of boric acid on the base. Or, the necessary proportions of hexamethylenamine and boric acid may be mixed, and the product dried.—F. Sndn.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 828.)

Light; The chemical action of ——. F. E. Menter. Phot. Corr., 1906, 43, 311; Chem.-Zeit., 1906, 30, Rep. 260.

The author has studied the products obtained by the interaction of a number of organic oxidising and reducing agents in presence of light. The action of light on di-iodo-acetylene is particularly interesting, since it causes separation of carbon according to the equation: $2C_2I_2 = C_2I_4 + C_2$.—B. J. S.

English Patents.

Photographic papers; Process for making ——. I. Hoffsümmer, Düren, Germany. Eng. Pat. 2057, Jan. 26, 1906.

See First Addition to Fr. Pat. 357,453 of 1905; following these.—T. F. B.

Photography; Sensitive plate for colour ——. B. J. B. Mills, London. From Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils, Lyon-Monplaisir, France. Eng. Pat. 9100, April 19, 1906.

In Eng. Pats. 22,988 and 25,718 of 1904 (this J., 1905, 104 and 152), plates for colour photography are described in which the spaces between the coloured particles (between sensitive film and support) are filled with a black powder. This filling is obviated by the present invention, which consists in coating the support with an adhesive layer, and applying the coloured particles as before, and then bringing the particles of starch to a suitable hygrometric condition, whereby they can be submitted to direct pressure or to rolling, so as to form a coating covering the entire support, and to which the sensitive film is applied. —T. F. B.

Reproduction of pictures by aid of catalytic action. A. G. Bloxam, London. From Neue Photographische Ges., Steglitz, Germany. Eng. Pat. 10,078, April 30, 1906.

Hydrogen peroxide, which plays an important part in the "catatype" process, is very liable to cause damage to sensitive papers, or to adhere to negatives and cause damage thereby. This is prevented by enclosing the papers or negatives in casings or envelopes made of fabric impregnated with a substance which will decompose hydrogen peroxide. The parts of the copying apparatus employed, which come into contact with the negative, may also be similarly protected. For instance, a protective substance can be prepared by impregnating textile fabric with an alkaline solution of potassium permanganate, and then drying it.—T. F. B.

United States Patent.

Photographic papers; Process for making ——. I. Hoffsümmer, Düren, Germany. U.S. Pat. 828,652, Aug. 14, 1906.

See First Addition to Fr. Pat. 357,453 of 1905; following these.—T. F. B.

French Patents.

p-Hydroxyphenylglycineamide; Process of producing ——. [*Photographic developer*]. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,449, May 8, 1905.

Equimolecular proportions of *p*-aminophenol and monochloroacetamide are allowed to react in presence of sodium acetate, an alkali carbonate, or similar acid absorbing agent; the resulting *p*-hydroxyphenylglycineamide, when recrystallised from water, has a m.pt. of 151° C., and is soluble in alcohol and ether. It is an energetic photographic developer, being employed as described in Eng. Pat. 9537 of 1905 (this J., 1906, 224). —T. F. B.

Development of the latent photographic image; Process for the ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,451, May 9, 1905.

See Eng. Pat. 9537 of 1905; this J., 1906, 224.—T. F. B.

Photographic papers; Process of making ——. I. Hoffsümmer. First and Second Additions, dated Jan. 30, 1906, to Fr. Pat. 357,453, Sept. 2, 1905.

The first Addition describes how the protective action of the intermediate layer of paper, &c. (see Eng. Pat. 17,303 of 1905; this J., 1905, 1189) may be increased by addition of further thin layers of paper or fabric. The second addition deals with the preparation of prints on a support composed of the substance which is to constitute the intermediate layer of the final print, the print being subsequently attached to the support of cheaper material. —T. F. B.

Papers; Process for preparing sensitive printing ——. Photochemischefabrik R. Risse G.m.b.H. Fr. Pat. 363,086, Feb. 8, 1906.

It is stated that paper, card, and the like, can be made very sensitive to light by treatment with mineral acids or with solutions of certain salts, sensitive forms of hydrocellulose or nitrocellulose being produced, the latter if nitric acid has been employed. Paper may be immersed for a short time in sulphuric acid (56°—66°) B., thoroughly washed, treated with dilute alkali, dried, and calendered. A concentrated solution of zinc sulphate is said to give similar results.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 828.)

Safety explosives; A study of ——. From the Laboratory of the Dynamit-Aktien Gesellschaft. A. Nobel and Co., Hamburg. Monit. Scient., 1906, 20, 595—610.

A large number of closed-vessel measurements were carried out on various powders in a bomb specially constructed for high densities of charge. The results go to show that, for explosives such as carbonite which give solid products of decomposition, increased density causes an increase in the carbon dioxide and methane formed, and a diminution of the hydrogen and carbon monoxide. Tables are given showing the heat evolved, the volume and composition of the gaseous products, the calculated temperature of explosion, and the pressure obtained, on firing: *carbonite carbonite, carbonite I. and II., water-dynamite (Nobel) I. and II., nobelite, extralite, fulminite, antiextralite, antifulminite*. The following is a comparison of the results obtained with these powders,—

Explosive.	Heat evolved—calories per grm.		Calculated Temp. of explosion (from vol. and press. of gases).	Volume of gases.	Expansion of standard* Trauzl cylinder.	Expansion compared with gelatin dynamite.	Safety of a 1 grm. charge.

Nitrocellulose; Decomposition of ——. O. Silberrad and R. C. Farmer. Chem. Soc. Trans., 1906, **89**, 1182—1186.

800 KILOS. of a gelatinised nitrocellulose were stored in a magazine which was maintained at a constant temperature of 54·4° C. by means of steam pipes, steam being also blown directly into the chamber in order to supply enough moisture to facilitate hydrolysis of the nitric ester. After 23 weeks, it was found that the tubes of nitrocellulose were in many instances filled with a crystalline deposit of oxalic acid. 100 kilos. of the explosive were now heated to 80° C. with an equal weight of water, and the solution filtered. The residue consisted of practically unaltered nitrocellulose. In the aqueous solution the presence of nitrous and nitric acids, ethyl nitrate and nitrite, excess of alcohol, ammonia, and also formic, acetic, butyric, dihydroxybutyric, oxalic, tartaric, isosaccharinic, and hydroxypyruvic acids, was detected. In another portion of the aqueous solution, after neutralising, and distilling off the alcohol, the presence of fermentable carbohydrates was detected by fermenting with yeast, when carbon dioxide was evolved, and the residue gave the iodoform reaction.—A. S.

Blasting explosives; Imports of ——, *into Great Britain.* Rept. of H.M. Inspector of Explosives for 1905 [T.R.]

THE imports of blasting explosives containing nitroglycerin into Great Britain in 1905 amounted to 3,234,485 lb., as against 2,244,723 lb. in 1904, an increase of about 44 per cent. There were also imported in 1905 a total of 278,736 lb. of blasting explosives not containing nitroglycerin. Of the total of 3,513,221 lb. of explosives imported in 1905, 2,883,267 lb., or about 82 per cent. was re-exported to other countries. The number of detonators imported during the year totalled 28,897,300, as against 15,279,412 in 1904, an increase of about 88 per cent. Of the 1905 imports there was re-exported 8,945,000.

Phosphorus; Detection of white —— *in match heads.* C. Van Eijk. XXIII., page 869.

ENGLISH PATENTS.

Explosives; Manufacture of ——. H. C. L. Bloxam and the Maganite Explosives Syndicate, Ltd, Cape Town. Eng. Pat. 3005, Feb. 7, 1906.

DINITROBENZENE and ammonium nitrate are fused and mixed together, and to the mixture a small quantity of ammonium carbonate is added. The following proportions have been found suitable:—82 parts of ammonium nitrate, 0·5 to 2·5 parts of ammonium carbonate, and 17 parts of dinitrobenzene.—B. J. S.

Explosives; Process and apparatus for distilling off and recovering the solvents used in the manufacture of ——. W. Nikolsky, St. Petersburg. Eng. Pat. 3661, Feb. 14, 1906.

IN order to recover the volatile solvents used in incorporating and pressing guncotton or similar materials into "cord," the explosive thus obtained is placed in a specially constructed chamber surrounded by a jacket of hot water. The vapour evolved is slowly pumped off and condensed, special care being exercised to prevent the formation of "blisters," which would interfere with the ballistic properties of the explosive.—B. J. S.

Guncotton; Process for imparting to —— *a greater intensity of explosive force.* T. Reishoff, Moscow. Eng. Pat. 10,927, May 10, 1906.

THE combustion of guncotton is rendered more complete by soaking it in a strong solution of metallic nitrates. The solution used contains 4 parts of potassium nitrate, 40 parts of ammonium nitrate, 1·7 parts of barium nitrate, 17 parts of sodium nitrate, 12·3 parts of strontium nitrate, and 25 parts of water by weight. Damp guncotton, 40 parts (containing about 15 per cent. of water) is soaked in 60 parts of the solution, or dry guncotton is used, and the requisite quantity of water added. In the case of compressed guncotton, sufficient solution is taken to fill all the pores, a much more powerful explosive being thus obtained.—B. J. S.

UNITED STATES PATENT.

Priming composition. K. W. Will, Grunewald, Berlin, Germany. U.S. Pat. 827,768, Aug. 7, 1906.

THE use of a mixture of certain specified proportions of tetranitromethylaniline and mercury fulminate is claimed.

—B. J. S.

FRENCH PATENT.

Powders; Process and apparatus for eliminating by distillation the solvent used in making smokeless ——, *or those giving little smoke.* W. Nikolsky. Fr. Pat. 363,519, Feb. 21, 1906.

SEE Eng. Pat. 3661 of 1906; preceding these.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 830.)

APPARATUS, &c.

Calibration of thermometers below 0° C.; New method for the ——. T. W. Richards and F. G. Jackson. Z. physik. Chem., 1906, **56**, 362—365.

THE undermentioned values are given for the depression of the freezing point of water by different proportions of hydrochloric acid, determined with a carefully standardised thermometer. By the use of a curve constructed from these values any thermometer can be readily calibrated. The method recommended for measuring the depression of freezing point is to immerse the thermometer, previously kept in ice for 24 hours, in a mixture of crushed ice and water, held in a cylindrical Dewar vacuum vessel. To the ice and water is added a solution of hydrochloric acid, and after well stirring, the thermometer is read, and

a 10 c.c. sample of the solution is taken with a pipette from the neighbourhood of the thermometer bulb, and submitted to analysis.

Depression of F.Pt.	Concentration, grm. equiv. per litre.	Weight of silver chloride per 10 c.c. of cold solution.

INORGANIC—QUALITATIVE.

Phosphorus; Detection of white —— in match heads. C. Van Eijk. Chem. Weekblad., 1906, 3, 367—371; 404—406. Chem. Centr., 1906, 2, 358—359.

The use of phosphorus sulphide, P_4S_3, in place of white phosphorus for the manufacture of match heads, suffers from the disadvantage that this compound gives the Mitscherlich reaction for white phosphorus. It may be distinguished from the latter, however, by determining the temperature at which it becomes luminous. A test-tube containing 250 mgrms. of the sulphide does not become luminous until a temperature above 70° C. is attained, whereas a tube containing 250 mgrms. of the sulphide with 0·02 per cent. of white phosphorus becomes luminous below 60° C. A better method is to extract the substance with carbon bisulphide, evaporate the solution, and distil the residue with lead acetate solution. The phosphorus sulphide is decomposed, and phosphorescence is observed only if white phosphorus be present. The presence of turpentine interferes with the detection of white phosphorus in phosphorus sulphide. If, however, at the point where, in the Mitscherlich method, steam is introduced into the condenser, water be allowed to drop in (compare Habermann and Oesterreicher, this J., 1902, 189), 0·2 per cent. of white phosphorus in phosphorus sulphide can be detected in presence of 4 per cent. of turpentine. By extracting the substance with carbon bisulphide, allowing the solution to evaporate in a dark chamber, and lightly rubbing the residue, 0·2 per cent. of white phosphorus in presence of 4 per cent. of turpentine, or 0·4 per cent. in presence of 6 per cent. of turpentine, can be detected by the appearance of phosphorescence.—A. S.

INORGANIC—QUANTITATIVE.

Nitric acid in commercial hydrochloric acid; Determination of small quantities of ——. B. N. Gottlieb. Chem.-Zeit., 1906, 30, 766.

The author remarks that the Lunge nitrometer can be used for the determination of small quantities of nitric acid in hydrochloric acid. The manipulation is the same as for the determination of nitric acid in sulphuric acid, with the exception that only hydrochloric acid is used. From 5 to 10 c.c. of the acid to be tested, are placed in the nitrometer, and the cup is rinsed with pure hydrochloric acid of 20° B. The author has obtained satisfactory results with acids containing 0·1—0·5 per cent. of nitric acid.—J. F. B.

Nitric oxide; Determination of —— in air, and some of the reactions involved. H. Le Blanc. Z. Elektrochem., 1906, 12, 581—585.

By allowing air to traverse an electric arc, nitric oxide, NO, and nitrogen peroxide, NO_2, are produced. The author discusses several methods (this J., 1905, 66) for determining the nitric oxide, and considers the following method the most satisfactory. The gas (partially decomposed air) is first of all shaken with a 1 per cent. solution of potassium hydroxide in order to absorb the nitrogen oxides. In the residue the oxygen is determined by shaking with pyrogallol.

The validity of the steps in the reactions involved here has been subjected to a careful examination. The reaction according to which nitrogen peroxide is absorbed by a potash solution is $2NO_2 + 2KOH = KNO_3 + KNO_2 + H_2O$. The proportions of nitrate and nitrite formed in this reaction have been submitted to careful measurement, and the ratio was found to be unity, as the equation demands. This is, however, only the case if the solution be analysed at once; if allowed to stand for a few minutes, the proportion of nitrate increases, owing to oxidation of the nitrite. The author has found that in some trials, when a high voltage (4000 volts) was used, the gases from the electric arc showed an excess of nitrite over nitrate. No satisfactory explanation of this can be given, but it is pointed out that, with suitable conditions, the yield of nitrite could probably be raised so as to be almost quantitative.—C. E. F.

Sulphur; Determination of —— in iron. W. Schulte. Stahl u. Eisen, 1906, 26, 985—991.

The author has confirmed a statement of Schindler's, made in 1893, that if iron be dissolved in strong hydrochloric acid, the whole of its sulphur is evolved as hydrogen sulphide; no organic sulphur compounds are formed, as they are when dilute acid is used, and hence an accurate determination of the sulphur is possible without the troublesome ignition of the evolved gases in an air-free atmosphere, which is necessary when dilute acid is used for the solution of the metal. The author's method is as follows:—10 grms. of the sample are placed in a flask provided with a ground stopper which carries a tap-funnel reaching nearly to the bottom of the flask, and a delivery tube (preferably provided with a stop-cock). This is connected by rubber tubing with a wash-bottle containing 160 c.c. of water, the exit tube of which is in turn connected with a form of absorption flask containing about 35 c.c. of cadmium acetate solution (25 grms. of cadmium acetate, or 5 grms. of cadmium acetate and 20 grms. of zinc acetate, dissolved in 250 c.c. of water and 250 c.c. of glacial acetic acid, and then made up to a litre). By means of the tap-funnel two successive quantities of 50 c.c. each of hydrochloric acid (sp. gr., 1·19) are delivered upon the iron, as rapidly as is consistent with a not too violent evolution of gas (3—4 bubbles per second through the wash-bottle). When the evolution slackens, a Bunsen burner with a luminous flame, 7 mm. high, protected by a chimney, is brought under the flask and about 6 cm. below it. The flame is very gradually raised, as necessary, to about 2½ cm., and kept at that height till all the iron is dissolved (1—1½ hours). The flame is then heightened, and air admitted to the burner, so that the liquid boils (the funnel-tap being opened to avoid accidental sucking back), and gentle boiling is continued for about eight minutes. The burner is now moved to the wash-bottle, and when the water boils, the stop-cock between wash-bottle and flask is closed, and the boiling continued. When the cadmium acetate solution is heated practically to boiling by the steam, the wash-bottle connection is broken, and the burner removed. All of the hydrogen sulphide will now have been driven into the cadmium solution. To determine the sulphur, there are now added to the contents of the absorption flask 5 c.c. of copper sulphate solution (1 litre contains 130 grms. of the crystallised salt and 120 c.c. of concentrated sulphuric acid), the flask is well shaken, the copper sulphide collected on a 7 cm. ashless filter, well washed, still burnt off (raising the temperature very gently) to cupric oxide, from the weight of which the sulphur is calculated.

The author has proved that the gases passing the cadmium solution contain no sulphur in any form, and that the results agree with those obtained by the usual titrimetric oxidation methods.—J. T. D.

ORGANIC—QUALITATIVE.

Butter; The Polenske method for the detection of cocoanut oil in ——. S. Rideal and H. G. Harrison. Analyst, 1906, **31**, 254—258.

The authors have examined by the Polenske method (this J., 1904, 387) a number of pure English butters, as well as butters of unknown origin. They find that the distillates from pure butters do not give "soluble" and "insoluble" figures in strict ratio, but that, starting with a pure butter fat, the admixture of cocoanut oil causes the relative increase in the "insoluble" figure to agree with Polenske's results. The figures obtained, are given in tabular form, and from them curves have been constructed, the "insoluble" figures being plotted against the "soluble." The English butters gave a curve lying considerably below that for Polenske's butters, whilst the curve for the butters of unknown origin, lay between the other two. Between the figures found by the authors and those of Polenske, there is such a divergence that an appreciable margin of possible adulteration may be inferred.—W. P. S.

ORGANIC—QUANTITATIVE.

Coals and lignites; Determination of volatile combustible matter in ——. E. E. Somermeier. J. Amer. Chem. Soc., 1906, **28**, 1002—1013.

With some samples of lignite the author has found it to be impossible to obtain closely-agreeing duplicate results when using the method recommended in the Report of the Committee on Coal Analysis appointed by the American Chemical Society, for the determination of volatile combustible matter (see this J., 1898, 608). The results of a considerable number of experiments, carried out with a view of explaining these discrepancies, show that the value obtained for volatile matter in coal is affected to an important degree by the method of heating the sample, by the fineness of the pulverisation, and by the amount of loosely held moisture present. In bituminous coals these differences do not exceed 3 or 4 per cent., and appear to be due entirely to the different breaking up of the hydrocarbon compounds under varying conditions of heating, fineness of the sample, and amount of moisture present. In the case of lignites, where the difference between duplicate determinations may be as high as 25 per cent., it is due largely to the mechanical loss in the sample during the rapid expulsion of the volatile matter. Finer ground samples give a somewhat lower amount of volatile matter than do coarser samples. Whilst the official method may be taken as giving correct results in cases where mechanical loss cannot be shown, it does not necessarily give a result approximating very closely the volatile matter as given off when the coal is burnt under a steam-boiler, where the conditions more nearly resemble a method described by the author, in which the coal is subjected to a preliminary heating at a low temperature before being heated as recommended in the official method. It is considered desirable that the latter method be modified in order to prevent mechanical loss in the case of lignites.—W. P. S.

Starch [in cereals]; Determination of ——. B. Gschwendner. Chem.-Zeit., 1906, **30**, 761—763.

The author proposes the following simplified method for the determination of starch in cereals: 5—7·5 grms. of meal are placed in a 50 c.c. measuring flask together with 25—30 c.c. of acidified brine, and the mixture is thoroughly shaken until the meal is uniformly suspended in the liquid. The acid brine is prepared by dissolving 100 grms. of salt in 400 c.c. of water and adding to the solution 50 c.c. of 23 per cent. hydrochloric acid. The flask is then attached to a reflux condensing tube, and is heated in a calcium chloride bath (b.pt., 107°—110° C.) for 1½ hour. At the end of that time 5 c.c. of basic lead acetate solution are added, the contents of the flask are cooled, and diluted to the mark. An excess of water corresponding to the volume of the undissolved residue is added, *viz.*, in the case of maize-flour, 0·7 c.c. per 5 grms. of flour. The solution is then filtered and polarised. The polarisation value is calculated as dextrose, and the result × 0·9 gives the quantity of starch. Reasonable variations in the concentration and time of heating have no influence on the results, but it is not advisable to hydrolyse solutions containing more than 20 per cent. of meal. The results are lower than those obtained by the high-pressure conversion method, but slightly higher than those found by the diastase method, in which traces of starch remain unconverted. The author has only investigated the method fully for the valuation of maize; the analysis is effected with the minimum expenditure of time and trouble.—J. F. B.

Fermentable matter in grain; Determination of ——. Boidin and de Lavallée. Bull. Assoc. Chim. Sucr. et Dist., 1906, **23**, 1383—1384.

The principal causes of error in starch determinations by chemical methods are: 1. Non-fermentable bodies are reckoned as starch; 2. During the acid hydrolysis of the dextrin a portion of the sucrose is destroyed. The authors suggest the following method, a process of determination by means of fermentation:—The whole or ground grain is boiled with an organic or mineral acid under a low pressure for a very short time (until the starch is liquefied). The pasty solution thus obtained is transferred to a flask, the neck of the latter is closed with a cotton-wool plug, and the whole sterilised. After cooling, the acid is neutralised with sterilised chalk, the neutralised solution then being treated with a saccharifying mucedina and pure yeast. This method, which is an exact copy of the commercial amylo process, possesses the following advantages:—

1. The inclusion of non-fermentable substances such as the pentoses as fermentable matter, is avoided.

2. By the use of mucedine in an aseptic medium, a fermented solution is obtained which contains neither reducing sugar nor starch.

3. Nearly the theoretical yield is obtained.

4. Analytical details may be modified to any degree, so that in the majority of cases the yield on the large scale may be calculated, thus rendering it possible to detect any faults in the manufacture.—L. E.

Malic acid and other fixed acids; Determination of —— *in fruit juices.* W. Mestrezat. Compt. rend., 1906, **143**, 185—186.

The method is based on the insolubility of barium malate, tartrate, and succinate in 75 per cent. alcohol. A known volume of the fruit juice is neutralised with barium hydroxide, a few drops of 3 per cent. acetic acid added, the whole concentrated *in vacuo*, 2 c.m. of a 30 per cent. barium acetate added and enough alcohol to bring the alcohol content to 80 per cent. The precipitate contains the barium salts of the acids, also the gums, pectins, albuminoids, and tannins; whilst the clear solution contains the sugar, glycerol, soluble barium salts, and other substances. The precipitate has enough sulphuric acid added to it to decompose the barium salts, along with 10—12 c.c. of water, and the whole is made up to 100 c.c. with alcohol, when the gums, pectins, and albuminoids are precipitated. Eighty c.c. of the filtered liquid are taken, potassium chloride and acetate added, and the volume made up to 100 c.c. with water, whereby the whole of the tartaric acid is precipitated. From the filtrate the barium malate and succinate are precipitated as above, dissolved in water, and the tannin removed by precipitation with Laborde's mercury acetate solution. The malic acid is estimated by oxidation with permanganate, the solution being then evaporated to dryness with sand, and the succinic acid extracted from the residue with ether.—E. F. A.

a 10 c.c. sample of the solution is taken with a pipette from the neighbourhood of the thermometer bulb, and submitted to analysis.

Phosphorus; Detection of white —— in match heads. C. Van Eijk. Chem. Weekblad., 1906, 3, 367—371; 404—406. Chem. Centr., 1906, 2, 358—359.

The use of phosphorus sulphide, P_4S_3, in place of white phosphorus for the manufacture of match heads, suffers from the disadvantage that this compound gives the Mitscherlich reaction for white phosphorus. It may be distinguished from the latter, however, by determining the temperature at which it becomes luminous. A test-tube containing 250 mgrms. of the sulphide does not become luminous until a temperature above 70° C. is attained, whereas a tube containing 250 mgrms. of the sulphide with 0·02 per cent. of white phosphorus becomes luminous below 60° C. A better method is to extract the substance with carbon bisulphide, evaporate the solution, and distil the residue with lead acetate solution. The phosphorus sulphide is decomposed, and phosphorescence is observed only if white phosphorus be present. The presence of turpentine interferes with the detection of white phosphorus in phosphorus sulphide. If, however, at the point where, in the Mitscherlich method, steam is introduced into the condenser, water be allowed to drop in (compare Habermann and Oesterreicher, this J., 1902, 189), 0·2 per cent. of white phosphorus in phosphorus sulphide can be detected in presence of 4 per cent. of turpentine. By extracting the substance with carbon bisulphide, allowing the solution to evaporate in a dark chamber, and lightly rubbing the residue, 0·2 per cent. of white phosphorus in presence of 4 per cent. of turpentine, or 0·4 per cent. in presence of 6 per cent. of turpentine, can be detected by the appearance of phosphorescence.—A. S.

INORGANIC—QUANTITATIVE.

Nitric acid in commercial hydrochloric acid; Determination of small quantities of ——. B. N. Gottlieb. Chem.-Zeit., 1906, 30, 766.

The author remarks that the Lunge nitrometer can be used for the determination of small quantities of nitric acid in hydrochloric acid. The manipulation is the same as for the determination of nitric acid in sulphuric acid, with the exception that only hydrochloric acid is used. From 5 to 10 c.c. of the acid to be tested, are placed in the nitrometer, and the cup is rinsed with pure hydrochloric acid of 20° B. The author has obtained satisfactory results with acids containing 0·1—0·5 per cent. of nitric acid.—J. F. B.

Nitric oxide; Determination of —— in air, and some of the reactions involved. H. Le Blanc. Z. Elektrochem., 1906, 12, 581—585.

By allowing air to traverse an electric arc, nitric oxide, NO, and nitrogen peroxide, NO_2, are produced. The author discusses several methods (this J., 1905, 66) for determining the nitric oxide, and considers the following method the most satisfactory. The gas (partially decomposed air) is first of all shaken with a 1 per cent. solution of potassium hydroxide in order to absorb the nitrogen oxides. In the residue the oxygen is determined by shaking with pyrogallol.

The validity of the steps in the reactions involved here has been subjected to a careful examination. The reaction according to which nitrogen peroxide is absorbed by a potash solution is $2NO_2 + 2KOH = KNO_3 + KNO_2 + H_2O$. The proportions of nitrate and nitrite formed in this reaction have been submitted to careful measurement, and the ratio was found to be unity, as the equation demands. This is, however, only the case if the solution be analysed at once; if allowed to stand for a few minutes, the proportion of nitrate increases, owing to oxidation of the nitrite. The author has found that in some trials, when a high voltage (4000 volts) was used, the gases from the electric arc showed an excess of nitrite over nitrate. No satisfactory explanation of this can be given, but it is pointed out that, with suitable conditions, the yield of nitrite could probably be raised so as to be almost quantitative.—C. E. F.

Sulphur; Determination of —— in iron. W. Schulte. Stahl u. Eisen, 1906, 26, 985—991.

The author has confirmed a statement of Schindler's, made in 1893, that if iron be dissolved in strong hydrochloric acid, the whole of its sulphur is evolved as hydrogen sulphide; no organic sulphur compounds are formed, as they are when dilute acid is used, and hence an accurate determination of the sulphur is possible without the troublesome ignition of the evolved gases in an air-free atmosphere, which is necessary when dilute acid is used for the solution of the metal. The author's method is as follows:—10 grms. of the sample are placed in a flask provided with a ground stopper which carries a tap-funnel reaching nearly to the bottom of the flask, and a delivery tube (preferably provided with a stop-cock). This is connected by rubber tubing with a wash-bottle containing 160 c.c. of water, the exit tube of which is in turn connected with a form of absorption flask containing about 35 c.c. of cadmium acetate solution (25 grms. of cadmium acetate, or 5 grms. of cadmium acetate and 20 grms. of zinc acetate, dissolved in 250 c.c. of water and 250 c.c. of glacial acetic acid, and then made up to a litre). By means of the tap-funnel two successive quantities of 50 c.c. each of hydrochloric acid (sp. gr., 1·19) are delivered upon the iron, as rapidly as is consistent with a not too violent evolution of gas (3—4 bubbles per second through the wash-bottle). When the evolution slackens, a Bunsen burner with a luminous flame, 7 mm. high, protected by a chimney, is brought under the flask and about 6 cm. below it. The flame is very gradually raised, as necessary, to about 2½ cm., and kept at that height till all the iron is dissolved (1—1½ hours). The flame is then heightened, and air admitted to the burner, so that the liquid boils (the funnel-tap being opened to avoid accidental sucking back), and gentle boiling is continued for about eight minutes. The burner is now moved to the wash-bottle, and when the water boils, the stop-cock between wash-bottle and flask is closed, and the boiling continued. When the cadmium acetate solution is heated practically to boiling by the steam, the wash-bottle connection is broken, and the burner removed. All of the hydrogen sulphide will now have been driven into the cadmium solution. To determine the sulphur, there are now added to the contents of the absorption flask 5 c.c. of copper sulphate solution (1 litre contains 130 grms. of the crystallised salt and 120 c.c. of concentrated sulphuric acid), the flask is well shaken, the copper sulphide collected on a 7 cm. ashless filter, well washed, still burnt off (raising the temperature very gently) to cupric oxide, from the weight of which the sulphur is calculated.

The author has proved that the gases passing the cadmium solution contain no sulphur in any form, and that the results agree with those obtained by the usual titrimetric oxidation methods.—J. T. D.

(1) These articles formerly paid also the duty on alcohol at the rate of 4·66 lire per kilo.
(2) No distinction is made between pure and impure fish oils under the present Law.
(3) As sugar of the first class.
(4) Of first class, superior to No. 20 Dutch standard in colour.
(5) Of second class.
(6) Liquid containing 50 per cent. or more of acetic acid.
(7) Crystallised.
(8) As nitrate of silver.

A LIST OF OFFICIAL CHEMICAL APPOINTMENTS HELD IN GREAT BRITAIN AND IRELAND, IN INDIA AND THE COLONIES. Compiled by direction of the Council of the Institute of Chemistry, and under the supervision of the Proceedings Committee, by RICHARD B. PILCHER (Fellow of the Chartered Institute of Secretaries), Registrar and Secretary of the Institute of Chemistry. June, 1906. The Institute of Chemistry of Great Britain and Ireland, 30, Bloomsbury Square, London, W.C. Price, 2s. net. Post free, 2s. 3d.

8vo volume, containing 123 pages of subject matter, the table of contents at the beginning serving all the purposes of index. The object of the publication is stated to be "to provide and maintain a list of official appointments which are held by professional chemists, and professors and teachers of chemistry." The list is arranged in two main divisions:—The first contains appointments under the various departments of State, and professional and teaching appointments in Great Britain and Ireland; the second containing appointments in the Empire of India, the Dominion of Canada, the Commonwealth of Australia, and the British Colonies and Protectorates, including New Zealand. The work ends with an Appendix, devoted to Chemical Societies and Institutions. It is stated that "Suggestions which may increase the usefulness of the list will be welcomed, and should be addressed to the Registrar."

LEHRBUCH DER ANORGANISCHEN CHEMIE. Von Dr. H. ERDMANN. Director des Anorg. Chem. Instituts der königl. tech. Hochschule zu Berlin. 4te Auflage. Friedrich Vieweg und Sohn's Verlagsbuchhandlung. Braunschweig, 1906. Price 15M., or bound, 16M. or 17M.

8vo volume, containing 744 pages of matter, with 303 illustrations, 95 tables, a calculations table, and 7 coloured tables (spectra). There are indexes of subjects and of authors. The matter is classified in the following groups:—I. INTRODUCTION TO CHEMISTRY. II. THE METALLOIDS, general properties and distribution. (i) Chief Gases; (ii) Rare Gases; (iii) Air; (iv) Sulphur Group; (v) Halogens; (vi) Phosphorus Group; (vii) Carbon Group. III. THE METALS, with supplementary group, containing Osmium, Ruthenium and Tellurium. IV. GENERAL MATTER ON THE PROPERTIES OF THE ELEMENTS AND THEIR COMPOUNDS.

ELEKTROLYTISCHE ALKALICHLORIDZERLEGUNG MIT FLÜSSIGEN METALLKATHODEN. (Monographien über angewandte Elektrochemie.) Von Dr. R. LUCION. Wilhelm Knapp's Verlag. Halle a. S., 1906. Price 9M.

8vo volume, containing 204 pages of subject-matter, and an alphabetical index of names only, the subjects being taken as indexed by means of the table of contents at the beginning of the work. The matter is thus classified:—PART I. PROCESSES WITH THE MERCURY CATHODE. (i) Theory of the Electrolysis of Alkali Chlorides with the mercury Cathode; (ii) Practical Difficulties, &c.; (iii) Description of the Patented Processes; (iv) Historical; (v) Costs of Preparation, &c. PART II. PROCESSES WITH FUSED METALLIC CATHODES. (i) General; (ii) Practical Difficulties; (iii) The Patented Processes; (iv) Results.

LECTURE NOTES ON CHEMISTRY FOR DENTAL STUDENTS, INCLUDING DENTAL CHEMISTRY OF ALLOYS, AMALGAMS, &C. SUCH PORTIONS OF ORGANIC AND PHYSIOLOGICAL CHEMISTRY AS HAVE PRACTICAL BEARING ON THE SUBJECT OF DENTISTRY, INORGANIC QUALITATIVE ANALYSIS, &C., AND THE CHEMICAL EXAMINATION OF URINE AND SALIVA. By H. CARLTON SMITH, Ph.G., Lecturer on Physiological Chemistry at Harvard University Dental School, &c. John Wiley and Sons, New York. 1906. Price 10s. 6d. Chapman and Hall, Ltd., London.

8vo volume, containing 250 pages of subject-matter, 6 further pages of appendix, and the alphabetical index, followed by nine plates of microscopic figures. The work is illustrated further by 21 engravings.

Part II. of the work deals with the subject of DENTAL METALLURGY, and is sub-divided into I. The Metals. II. Alloys. III. Amalgams. IV. Dental Cement. V. Solders and Fusible Metals. VI. Recovery of Residue.

MODERN [AMERICAN] SOAPS, CANDLES, AND GLYCERIN. A Practical Manual of Modern Methods of Utilisation of Fats and Oils in the Manufacture of Soap and Candles, and of the Recovery of Glycerin. By LEBBERT LLOYD LAMBORN. D. van Nostrand Co., 23, Murray and 27, Warren Streets, New York. Crosby, Lockwood and Sons, 7, Stationers' Hall Court, Ludgate Hill, London, E.C. 1906. Price 30s. net.

LARGE 8vo volume, containing 665 pages of subject-matter, followed by an appendix with tables, filling 18 pages, and the alphabetical index. There are 225 illustrations. The text is sub-divided as follows:—I. The Soap Industry. II. and III. Raw Materials of Soap Manufacture. IV. Bleaching and Purification of Soap-stock. V. Chemical Characteristics of Soap-stock and their Behaviour towards Saponifying Agents. VI. Mechanical Equipment of the Soap Factory. VII. Cold Process and Semi-boiled Soap. VIII. Grained Soap. IX. Settled Rosined Soap. X. Milled Soap Base, Floating Soap, Shaving Soap, Medicated Soap. XI. Essential Oils and Soap Perfumery. XII. Milled Soap. XIII. Candles. XIV. Glycerin. XV. Examination of Raw Materials and Factory Products.

XXI.	Photographic Materials and Processes	910
XXII.	Explosives, Matches, &c.	910
XXIII.	Analytical Chemistry	911
XXIV.	Scientific and Technical Notes	913

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6d. each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 590 pages, was published in 1899; a few copies of this are still left, price 10s. A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform, in size, with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10s. each copy. A form of application for this purpose will shortly be issued.

CORRECTIONS FOR DECENNIAL INDEX.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

Changes of Address.

Allen, Wilfrid T.; all communications to Allington, Bexley, Kent.

Baron, Wm. Briscoe, l/o Warrington; c/o The Fuel Testing and Water Saving Co., Ltd., 2, Booth Street, Albert Square, Manchester.

Brunt, R. A., l/o Box 121; Box 71, Windsor, Ont., Canada.

Carpenter, H. C. H., l/o Teddington; 11, Oak Road, Withington, Manchester.

Craven, J. A., l/o The Hollies; 119, Town Street, Armley Leeds.

Eddy, Wm. C.; all communications to "Corner of" Glover and Penn Streets, Woodbury, N.J., U.S.A.

Enright, Bernard, l/o South Bethlehem; c/o St. Louis Portland Cement Co., St. Louis, Mo., U.S.A.

Fingland, Jno. J., l/o Glasgow; Rosebery, B.C., Canada.

Goetz, Isidore, l/o Northwood; 5, Brondesbury Park, London, N.W.

Grabfield, Dr. J. P., l/o Chicago; c/o Monds and Co., 35th Street and 11th Avenue, New York City, U.S.A.

Gries, Walter T., l/o London; 9, Dalhousie Square, Calcutta, India.

Haigh, Percy, l/o Cambridge; St. Catherine's, Hurst-pierpoint, Sussex.

Hall, Clarence A., l/o North American Building; 51, Allen Lane, Mount Airy, Philadelphia, Pa., U.S.A.

Imrie, John, l/o Glasgow; Station Road, Milton, Stoke-on-Trent.

Johnson, Chas. C.; Journals to 4734, Fairview Avenue, Windsor Place, Olds, U.S.A.

Joseph, A. F., l/o London; Royal College, Colombo, Ceylon.

Knecht, Dr. E., l/o Crumpsall; all communications to Beech Mount, Marple, Cheshire.
Lansley, Thomas Ley, c/o Chas. Harrington, c/o Waterbury Buckle Co., Waterbury, Conn., U.S.A.
Miller, Stuart B., l/o Birmingham; c/o Eastern Dynamite Co., Lewisburg, Ala., U.S.A.
Nash, L. Hyddelton, l/o Seven Sisters Road; Westlands, Princess Road, Finsbury Park, N.
Page, E. P., l/o Heath Street; 31, Market Street, Stourbridge.
Patterson, C. A., l/o Landing, N.J.; Washburn, Wis., U.S.A.
Powney, W. E. F., l/o Stroud Green; 10, Alexandra Villas, Finsbury Park, N.
Scholes, Geo. R.; all communications to Dépôt Général de la Liebig's Extract of Meat Co., Ltd., Antwerp, Belgium.
Shenstone, W. A., F.R.S., l/o St. Vincent Rocks; 46, College Road, Clifton, Bristol.
Turnbull, R. H., l/o Smyrna; c/o McAndrew and Forbes Co., Camden, N.J., U.S.A.
Twigg, G. F., l/o Abbey Street; 29, Fairfax Road, Derby.
Williams, Percy, l/o Higham; 33, Oakfield Road, Clapton, N.E.
Witt, Dr. Otto N., l/o Siegmundshof; Ebereschenallee, 10, Westend bei Berlin.
Wrampelmeier, T. J., l/o Emerson Street; 2253, Piedmont Avenue, Berkeley, Cal., U.S.A.
Young, Dr. Geo., l/o Isle of Man; 83, Harvard Court Mansions, Honeybourne Road, West Hampstead, N.W.

Change of Address Required.

Johnstone, W. G., l/o 5, Great Winchester Street, E.C.

Death.

Pierce, Ira L., Washburn, Wis., U.S.A. July 16.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (1) in the case of Applications for Patents, the dates of Application, and (2) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 19,193, Merrell, Gere, and Merrell-Soule Co. Process and apparatus for recovering in the form of dry powder solids contained in liquids or semi-liquids.* Aug. 28.
" 19,412. Cowper-Coles and Sharp. Filters. Aug. 30.
" 19,663. Epstein. Furnaces or heating apparatus. Sept. 4.
" 19,729. Haddan (Aktiebolaget Separator). Centrifugal machines for separating solids from liquids.* Sept. 4.
" 19,922. Grossmann. Retort for distilling by means of or with the aid of open steam. Sept. 7.
" 19,957. Schmitt. Heating apparatus.* Sept. 7.
" 20,345. Bennis and Bennis. Furnaces. Sept. 12.
[C.S.] 18,172 (1905). Ungleub. Method and apparatus for distilling and evaporating liquids *in vacuo*. Sept. 19.
" 20,699 (1905). Kastner. Centrifugal fans or machines for atomising liquids. Sept. 12.
" 24,630 (1905). Fulton. Smoke-consuming furnace. Sept. 5.
[C.S.] 10,788 (1906). Kammermann. Drying or condensing apparatus. Sept. 19.
" 11,948 (1906). Marks and Blake. Production of non-oxidising protective gas for use with petroleum and other combustible liquids. Sept. 19.
" 11,623. (1906). Ridgway. Filters for separating solutions from solids. Sept. 12.
" 14,096 (1906). Haskell. Funnels. Sept. 12.

II.—FUEL, GAS, AND LIGHT.

[A.] 19,113. Bloxam (Henkels). Manufacture of incandescence mantles. Aug. 27.
" 19,115. Sellers, Capel, and Wallis. Generation of steam for conversion into water-gas in suction and pressure gas producer plants.* Aug. 27.
" 19,146. Dofays. Regenerating coke ovens. Aug. 27.
" 19,332. Moores and Petrides. Manufacture of air gas. Aug. 29.
" 19,398. British Thomson-Houston Co. (General Electric Co.). Graphite filaments for electric lamps, furnaces, &c. Aug. 30.
" 19,401. Thompson. Combustion of coal and other combustible material. Aug. 30.
" 19,480. Coppée. Regenerative coke ovens.* Aug. 31.
" 19,513. Hubbard. *See under* XXIII.
" 19,624. Robertson, and Willans and Robinson, Ltd. Apparatus for filtering gas.* Sept. 3.
" 19,629. Collins. Manufacture of briquettes. Sept. 3.
" 19,780. De Veiga. Process for utilising close burning coal dust for making metallurgical or other coke. [Fr. Appl., Sept. 12, 1905.]* Sept. 5.
" 20,042. Still and Adamson. Manufacture of incandescent gas mantles. Sept. 8.
" 20,085. Ling and Henry. Treatment of boiler, flue, and similar waste gases, and their subsequent utilisation. Sept. 10.
" 20,281. Robertson and Graham. Manufacture of artificial fuel. Sept. 12.
" 20,359. Fritz. Method of producing gas and its by-products from coal, peat, and similar substances. Sept. 13.
" 20,454. Green. Apparatus for producing combustible gas for lighting and heating purposes. Sept. 14.
" 20,484. Masons Gas Power Co., Ltd., Hollis and Wright. Power gas producers. Sept. 15.
[C.S.] 11,281 (1905). Drury and Pulman. Production of a combustible charge from oil, alcohol, or other liquid, for internal combustion engines. Sept. 5.
" 15,818 (1905). Le Maître. Manufacture of agglomerates, paint material, fuel briquettes, and the like. Sept. 12.
" 19,416 (1905). Grice. Gas producing plants. Sept. 12.
" 20,175 and 20,175a (1905). Just, Hänaman, Landesberger, Salzmann, and Verein. Electricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. Sept. 19.
" 21,124 (1905). Shadbolt and Tully. Gas manufacture. Sept. 19.
" 21,872 (1905). Stokes, and Stewart and Co. Gas calorimeter. Sept. 5.
" 22,974 (1905). Hutchins and Wilkie. Producer gas generators. Sept. 19.
" 23,902 (1905). Book. Manufacture of weather-proof briquettes with soluble binding materials. Sept. 12.
" 25,045 (1905). Hackert. Introduction of gas or steam into a gas retort. Sept. 12.
" 26,703 (1905). Tangye, Ltd., and Pain. Producer gas plants. Sept. 19.

[illegible] Sept. 5.

[illegible] Gas retorts. Sept. 19.

[illegible] (1906). Imray (Siemens und Halske A.-G.). Manufacture of incandescence bodies for electric lighting. Sept. 5.

6151 (1906). Boult (Soc. in Partecipazione per la Combustione Liquids). Hydrocarbon burners for furnaces. Sept. 19.

10,127 (1906). Hartenstein. Compositions for heating and maintaining the temperature of materials in the manufacture of carbide. Sept. 5.

10,159 and 10,160 (1906). Hartenstein. Carbide. Sept. 5.

12,127 (1906). Grünewald. Carburetting process and apparatus. Sept. 12.

12,128 (1906). Grünewald. Carburetting apparatus. Sept. 12.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 19,060. Gehre and Schultz. Process of preparing solvent naphtha.* Aug. 27.

" 19,477. Breda. *See under* XII.

" 19,761. Issakides and Deponte. Treatment of mineral oils used for lubricating and other purposes. Sept. 5.

" 19,811. Noad and Townsend. Refining mineral oil. Sept. 5.

[C.S.] 11,581 (1905). Drury and Pulman. *See under* II.

" 38 (1906). Stillesen. Manufacture of solidified petroleum for use as fuel. Sept. 19.

" 10,043 (1906). Martini and Huneke. *See under* I.

IV.—COLOURING MATTERS AND DYESTUFFS

[A.] 19,382. Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds of the anthracene series. Aug. 29.

19,602. Bierzam (Act.-Ges. f. Anilinfabr.). Manufacture of arylated derivatives of 2-amino-5-naphthol-7-sulphonic acid. Sept. 7.

19,736. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new dyestuffs of the triphenylmethane series. Sept. 10.

19,738. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series. Sept. 10.

19,807. Imray (Dyeworks, formerly Durand, Huguenin et Cie). Manufacture of condensation products from gallic acid or a derivative thereof and an alkylated amidoarylthioarsinic acid, and [illegible] thereof.* Sept. 11.

V.—FIBRES, YARNS, FABRICS, PAPER, PRINTING, AND [illegible] AND FIBROUS MATERIALS.

[A.] 19,195. Eichler. [illegible] of fabrics.* Aug. 23.

" 19,241 Wolman. *See under* IX.

" 20,000. Trevor. Colouring cloth. Sept. 5.

" 20,005. De Perini. Production [illegible] and paper pulp.* Sept. 5.

" 20,029. Stone. Dye tubs [illegible] Nov. 8, 1905.]* Sept. 5.

" 20,219. Ingham. Manufacture of [illegible] ing, stiffening or waterproofing [illegible] textile and like fabrics. Sept. 11.

" 20,220. Ingham. Manufacture of [illegible] Sept. 11.

" 20,460. Becker. Composition for [illegible] and rendering them non-inflammable.

" 20,494. Hunt and Mosses. [illegible] dyeing, scouring or otherwise treating [illegible] the open condition. Sept. 13.

" 20,519. Miller. Mercerising [illegible]

[C.S.] 20,279 (1905). Farnworth. [illegible] cloth or other fabrics. Sept. 12.

" 22,391 (1905). Calico Printers' Association and Warr. Production from certain [illegible] thickening suitable for calico printing and other purposes. Sept. 5.

" 6166 (1906). Gorrand. Manufacture of artificial silk. Sept. 5.

" 6671 (1906). Dydynski. Weaving [illegible] textile fabrics. Sept. 19.

VI.—COLOURING WOOD, LEATHER, PAPER, &c.

[A.] 20,119. Schwalbe. Process [illegible] colours fast to light and to [illegible]

VII.—ACIDS, ALKALIS, AND [illegible]

[A.] 19,172. Clarkson. Purification [illegible]

" 19,465. Wedekind und Co. [illegible] ammonium nitrate from [illegible] and ammonium sulphate. [Ger. appl. Nov. 28, 1905.]* Aug. 31.

" 19,649. Bamberger. [illegible] ide from dilute gases.

" 19,713. Tuells. Production [illegible] lead.* Sept. 6.

" 19,732. Kenyon. Production [illegible] insoluble in water.* Sept. 7.

" 20,037. Thomson. Utilising [illegible] galvanising iron. Sept. 8.

" 20,383. Lambert. Process [illegible] chlorine. Sept. 12.

" 20,498. Farnworth. [illegible]

[C.S.] 915 (1906). Digby and Marshall. Means for manufacturing hypochlorite solutions. Sept. 19.
,, 2047 (1906). Cooper. Production of cyanogen by products and compounds from humus. Sept. 19.
,, 2823 (1906). Teichner and Askenasy. *See under* XI.
,, 3905 (1906). Applegarth and Quain. Production of ozone. Sept. 12.
,, 4063 (1906). Krell. Tubes for concentrating acid. Sept. 5.
,, 9183 (1906). Newton (Dr. Wolters Phosphat Ges.). *See under* XV.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 20,507. Menzel. Process and apparatus for drawing window or plate glass.* Sept. 15.
[C.S.] 12,159 (1906). Slingluff. Glass furnaces. Sept. 12.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 19,070. Collins. Manufacture of imitation marble, stone, and the like. Aug. 27.
,, 19,186. Rauhoff. Rendering cement or concrete blocks waterproof.* Aug. 28.
,, 19,233. Kollen. Artificial stone.* Aug. 28.
,, 19,241. Wolman. Solutions for preserving wood and other fibrous material.* Aug. 28.
,, 19,349. Rigby and Roberts. Maturing Portland cement. Aug. 30.
,, 19,723. Yates. Manufacture of cement. Sept. 4.
,, 19,973. Matcham. Furnaces or kilns for preparing cement-making materials and the like.* Sept. 7.
,, 20,125. Schnell, Mayer, and Hartwich. Manufacture of a substitute for wood. Sept. 10.
,, 20,298. South, Payne, and Payne. Cement.* Sept. 12.
[C.S.] 3655 (1906). Jeroch, and Deutsche Ferrit-Cement Ges. Manufacture of cement. Sept. 5.
,, 3749 (1906). Bohmer. Materials for forming roadways. Sept. 19.
,, 7464 (1906). Price. Brick and like kilns. Sept. 5.
,, 8627 (1906). Crowley and Payne. Fireproof or heat-resisting surfacing composition or cement. Sept. 5.
,, 13,218 (1906). Wingfield. Bricks and the like. Sept. 12.

X.—METALLURGY.

[A.] 19,087. Brooks. Recovery of gold and silver from zinc-box slimes. Aug. 27.
,, 19,130. McIvor and Fradd. Treatment of sulphide ores containing zinc. Aug. 27.
,, 19,170. Churchward. Quenching or tempering baths for castings from steel alloys. Aug. 28.
,, 19,229. Clawson. Ore roasting and volatilising furnaces. Aug. 28.
,, 19,451. Lipscombe and Thoms. Metallic alloys. Aug. 31.
,, 19,452. Lipscombe and Thoms. Metallic alloys. Aug. 31.
,, 19,493. Hodgkinson. Treatment of iron or steel. Aug. 31.
,, 19,509. Swinburne. Treatment of sulphide or oxide ores. Sept. 1.
,, 19,554. Maunder. Smelting and treatment of complex, refractory, and other ores. Sept. 1.
,, 19,616. Drain. Open hearth furnaces.* Sept. 3.
[A.] 19,712. Snyder. Treatment of ores.* Sept. 4.
,, 19,813. Welch and Giddens. Aluminium solders. Sept. 6.
,, 19,815. Cowper-Coles. Recovery of gold from cyanide solutions. Sept. 6.
,, 19,944. Sulman. Ore concentration. Sept. 7.
,, 20,015. Fitzmaurice. Treatment of ores. Sept. 8.
,, 20,445. Crompton. Hardening steel. Sept. 14.
,, 20,452. Kelsall. Manufacture of high per cent. content manganese steel. Sept. 14.
,, 20,545. Maschinenbau-Anstalt Humboldt, and Metallurgische Ges. Separation of substances having different magnetic excitabilities. [Ger. Appl., Jan. 26, 1906.]* Sept. 15.
[C.S.] 10,943 (1905). Mac Ivor and Fradd. Process for extracting tin from ore. Sept. 5.
,, 17,449 (1905). Chance. Process for purifying metals. Sept. 5.
,, 17,839 (1905). Blackmore and Howard. Treatment of pyritic ores containing gold, silver, or other valuable metals. Sept. 5.
,, 23,408 (1905). Asbeck. Process for obtaining lead and silver from their ores. Sept. 19.
,, 26,277 (1905). Heberlein. Treatment of metalliferous ores or compounds preparatory to smelting. Sept. 19.
,, 60 (1906). King. Desulphurising and nodulising substances containing iron compounds. Sept. 12.
,, 4999 (1906). Hodgkinson. Treatment of small mine or waste products of calcined iron ores for the more complete extraction of iron. Sept. 12.
,, 8507 (1906). Hunter. Conversion of cast iron into steel or malleable iron. Sept. 12.
,, 12,599 (1906). Gruber. Soldering aluminium or its alloys, and solder therefor. Sept. 5.
,, 13,931 (1906). Cattaneo and Faggian. Preparation for converting iron into steel and for tempering steel. Sept. 12.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 19,398. British Thomson-Houston Co. (General Electric Co.). *See under* II.
,, 19,411. Cowper-Coles. Electrodeposition of alloys. Aug. 30.
,, 20,054. Mackenzie (Bolle und Co.). Production of metallic salts by electrolysis.* Sept. 8.
,, 20,380. Cowper-Coles. Electrolytes for the electrodeposition of copper. Sept. 13.
[C.S.] 17,727 (1905). Lewis and Corey. Electrodeposition of metals. Sept. 12.
,, 18,513 (1905). Lederer. Process of making emulsions of mercury or other conducting substances. Sept. 19.
,, 19,111 (1905). Hess. Manufacture of a substance for electrical insulation. Sept. 12.
,, 25,771 (1905). Frick. Electric transformer furnaces. Sept. 12.
,, 52 (1906). Jeantaud. Special active material for accumulators. Sept. 12.
,, 1019 (1906). Gin. Electric furnaces. Sept. 12.
,, 2823 (1906). Teichner and Askenasy. Electrolytic production of persulphates. Sept. 12.
,, 3345 (1906). Connolly. Manufacture of insulating material. Sept. 12.
,, 4716 (1906). McDonald. Electrolytic apparatus. Sept. 19.
,, 7869 (1906). Pauling. Production of voltaic strong-current arcs. Sept. 5.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 19,477. Breda. Process of obtaining fatty acids from petroleum residues.* Aug. 31.

,, 19,605. Agostini. *See under* XIV.

,, 20,540. Rosa. Oils and greases, particularly for lubricating purposes. Sept. 15.

[C.S.] 4116 (1906). Wallbaum. Preparation of easily and durably emulsifiable fatty preparations. Sept. 12.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*A.*)—Pigments, Paints.

[A.] 20,552. Brindley. Manufacture of the pigment oxide of iron from waste liquors. Sept. 15.

[C.S.] 15,818 (1905). Le Maitre. *See under* II.

,, 27,252 (1905). Imray. (Meister, Lucius, und Brüning). Manufacture of colour lakes. Sept. 5.

(*B.*)—Resins, Varnishes.

[A.] 19,870. Snyder. Process of treating wood for the extraction of turpentine. [U.S. Appl., Dec. 1, 1905.]* Sept. 6.

,, 20,019. Joly. Gums, resins, and the like. Sept. 8.

,, 20,497. Lewkowitsch. Manufacture of varnish. Sept. 15.

[C.S.] 21,954 (1905). Harrison. Treating turpentine to render it uninflammable. Sept. 12.

(*C.*)—India-Rubber.

[A.] 19,886. Bonnefin. Process for extracting rubber from plants or parts of plants. Sept. 7.

,, 19,894. Gare. Process of reclaiming waste vulcanised india-rubber. Sept. 7.

,, 20,404. Olsson. Artificial gum or caoutchouc. Sept. 13.

[C.S.] 4692 (1906). Grätz. Processes for obtaining pure caoutchouc and the like. Sept. 5.

,, 8953 (1906). Beresin. Process of manufacturing artificial india-rubber. Sept. 5.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

[A.] 19,495. Lund. Process of fixing tanning fat in leather. [Appl. in Norway, Sept. 1, 1905.]* Aug. 31.

,, 19,557. Bernstein. Manufacture of an adhesive material from casein. Sept. 1.

,, 19,605. Agostini. Process for obtaining soap size.* Sept. 3.

,, 19,725. Ellis (Stoney and Wetherell). Adhesives. Sept. 4.

,, 19,848. Schneider. Process and apparatus for obtaining glue and gelatine from glue-materials in the form of powder or grits.* Sept. 6.

,, 20,548. Helbronner and Vallee. Treatment of ossein. [Fr. Appl., Sept. 26, 1905.]* Sept. 15.

[C.S.] 18,500 (1905). Smith. Apparatus for treating hides and leather. Sept. 19.

,, 14,602 (1906). Kohl. Manufacture of leather. Sept. 5.

XV.—MANURES, &c.

[C.S.] 9183 (1906). Newton (Dr. Wolters Phosphat Ges.). Process for rendering mixed combinations of phosphoric and silicic acid easily soluble. Sept. 19.

XVI.—SUGAR, STARCH, GUM, &c.

[A.] 19,464. Shaw. Process of extracting sugar from cane stalks. Aug. 31.

,, 20,488. Fielding. Production of soluble starch and dextrine. Sept. 15.

[C.S.] 10,822 (1905). Castle. Manufacture of gum tragasol from locust bean kernels. Sept. 5.

,, 18,138 (1905). Monti. *See under* XVII.

,, 16,535 (1906). W. H. Uhland Ges. Apparatus for moistening dextrine. Sept. 12.

XVII.—BREWING, WINES, SPIRITS, &c.

[A.] 19,140. Sleeman. Apparatus for malting grain. Aug. 29.

,, 19,324. Reul and Grund. Production of yeast. Aug. 29.

,, 20,144. Mackenzie (Deckebach). Process of treating and ageing wort.* Sept. 10.

[C.S.] 18,138 (1905). Monti. Treatment of wine must, beer, beetroot juice, and the like. Sept. 19.

,, 367 (1906). Somló. Preparation of grain for brewing and the like. Sept. 5.

,, 6640 (1906) Ehrlich. Process for making fusel oil and components of fusel oil. Sept. 19.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(*A.*)—Foods.

[A.] 19,321. Ransford (Lallemand). Substitutes for butter, lard, cream, and the like. Aug. 29.

,, 19,796. Goodall. Purifying and clarifying flour. Sept. 5.

[C.S.] 827 (1906). Driver. Beverages. Sept. 19.

,, 7936 (1906). Soc. "Le Lait." Process for preserving liquid foods. Sept. 19.

(*B.*)—Sanitation; Water Purification.

[A.] 19,727. Haddan (Edson Reduction Machinery Co.). Process for reducing garbage and sewage.* Sept. 4.

,, 19,728. Haddan (Edson Reduction Machinery Co.). Apparatus for reducing garbage and sewage.* Sept. 4.

,, 20,103. Candy. Manufactures for use in the purification and hardening of water. Sept. 10.

Journal and Patent Literature.

I.—PLANT, APPARATUS, AND MACHINERY.

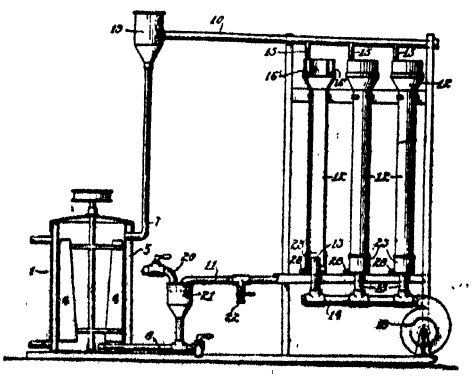
(*Continued from page* 840.)

English Patents.

Retorts or other appliances for heating or cooling solid, granular, or pasty materials, with or without simultaneous chemical treatment of the same with gases. J. Wetter, London. From E. R. Besemfelder, Charlottenburg, Germany. Eng. Pat. 18,593, Sept. 14, 1905.

The claim is for improvements in the apparatus described in Eng. Pat. 13,830 of 1899 (this J., 1900, 725). The coal or other material is moved through the heat-interchanging apparatus by imparting to the trough or retort an oscillating or vibratory movement, instead of turning the inclined retort on its axis.—W. H. C.

Drying apparatus. K. Reyscher, Bielefeld, Germany. Eng. Pat. 18,596, Sept. 14, 1905.



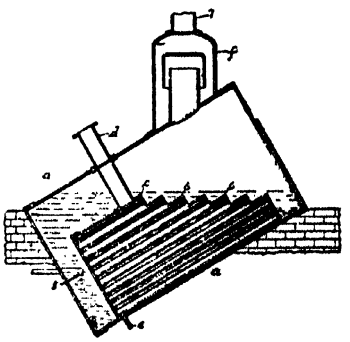
The apparatus consists of a long chamber or tunnel, through which the materials to be dried are caused to pass. There is a primary heating chamber under the centre of the tunnel, and a secondary heating chamber under each end. Air is drawn from the open ends of the tunnel, over the materials, and through the secondary heating chambers by fans, and is delivered into shallow chambers above the tunnel, from which it flows again over the materials to be dried. Air is also drawn from the centre of the tunnel by a compressor driven by an external motor; it is heated by the compression, and issues through the primary heating chamber to an air motor which drives the fans. It is thereby cooled, and the liquid which it has absorbed from the wet materials is condensed, and, if valuable, recovered. The only source of heat employed is the energy of the motor which heats the air by compression.—W. H. C.

Filter presses. M. Ekenberg, Stockholm. Eng. Pat. 6363, March 16, 1906.

See U.S. Pat. 818,154 of 1906; this J., 1906, 462.—T. F. B.

United States Patents.

Evaporating apparatus. F. D. Smith, Los Angeles, Cal. U.S. Pat. 828,343, Aug. 14, 1906.



The liquid to be evaporated is fed from the tap, 20, into the tank, 21, from which it flows by the pipe, 6, into the cylinder, 1, provided with a heating jacket, 5. An agitator, 4, drives the liquid from the inlet, 6, to the outlet, 7, and to the tank, 19. From 19, the liquid flows along the pipe, 10, out of the tubes, 15, into the annular cups, 16¹, of the evaporator tubes, 12, down which it flows and meets an ascending current of air delivered through the tubes, 14, 13, by the fan, 18. The concentrated liquid flows from the annular cups, 23, at the bottom of the pipes, by the tubes, 28, into the main, 11, from which it is either drawn off by the tap, 22, or is returned to the tank, 21, for circulation over again.—W. H. C.

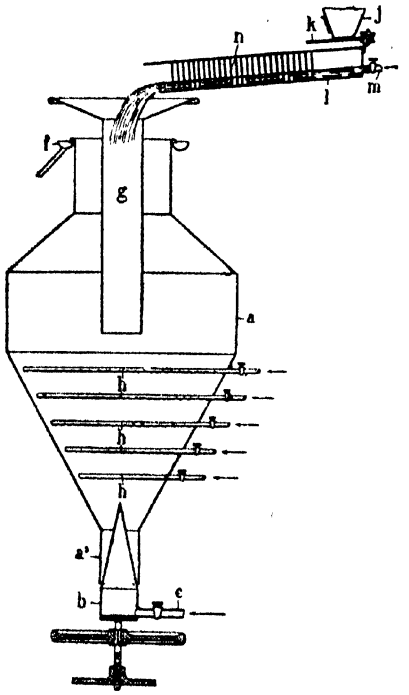
Evaporating apparatus. J. A. Warren, Westbrook, Me., Assignor to S. D. Warren, W. B. Mason, and F. Warren, Boston, Mass. U.S. Pat. 828,524, Aug. 14, 1906.

An evaporator, having a supply chamber below and a vapour chamber above, connected by vertical evaporator pipes which pass through a steam chamber, has a discharge pipe provided with an overflow bend, which has a telescopic joint to regulate and determine the "hydrostatic level" of the liquid in the tubes. The vapour and supply chambers are connected by a return pipe, and the overflow of the vapour chamber has a siphon-breaking pipe with a telescopic joint.—W. H. C.

Evaporator. F. Scherr, Roosevelt, N.Y. U.S. Pat. 828,085, Aug. 14, 1906.

A cylindrical outer shell, *a*, is set at an angle as shown, and has an interior cylinder, *c*, placed eccentrically within it. The inner cell, *c*, has a straight lower end, and a stepped or "staggered" upper one, so that the upper ends of the tubes which pass through it are approximately in the same horizontal plane. The liquid to be evaporated enters by the pipe, 8, and passes through the tubes of the inner cylinder, *c*, and the vapour given off escapes through the dome, *f*, and the pipe, 7. Steam enters the space round the tubes through the pipe, *d*, and the condensed water escapes through the pipe, *e*.—W. H. C.

Drying-machine; Continuous roller ——. B. Cohnen, Grevenbroich, Germany. U.S. Pat. 829,141, Aug. 21, 1906.



A vertical series of shelves, formed of a number of rollers placed close together in horizontal rows, is enclosed in a casing through which a current of warm air or other suitable drying medium is circulated. Alternate rows of rollers are rotated in opposite directions, so that the material which is fed on the top row is moved forward, and dropped on to the second row at the other end through a space left between the shelf and the end of the case at the opposite ends of alternate shelves. The material is moved alternately backwards and forwards until it reaches the bottom shelf, from the end of which it is discharged.—W. H. C.

Filter. C. Sellenscheidt, Assignor to Filter und Brautechnischen Maschinenfabrik A.-G., vorm. L. A. Enzinger, Berlin. U.S. Pat. 829,807, Aug. 28, 1906.

SEE Eng. Pat. 11,979 of 1904; this J., 1905, 268.—T. F. B.

FRENCH PATENTS.

Purification, methodical classification, and concentration of all kinds of materials; Process and apparatus for ——. L. A. Morel. Fr. Pat. 361,513, May 26, 1905.

THE materials to be treated, previously brought into a fine state of division, are delivered from the hopper, *j*, on to the distributor, *k*, and are mixed with water or other suitable liquid from the pipe, *m*, in the shoot, *l*, down which the mixture flows through the gratings, *n*, into the funnel tube, *g*. The mixture enters the vessel, *a*, which is full of water, and separates into two portions, one lighter and the other heavier than water. A current of water forced in through the tube, *c*, and the hollow plug, *b*, agitates the mixture, and facilitates the separation. The lighter particles are carried to the top of the vessel, *a*, and flow over the lip into the trough, *f*, and the heavier portions sink and collect at the bottom at a^2. They are removed from time to time by loosening the hollow plug, *b*. The agitation and separation are further assisted by injecting water and air through the pipes, *h*. —W. H. C.

Evaporation; New apparatus for ——. J. F. P. Kestner. Fr. Pat. 361,524, May 29, 1905.

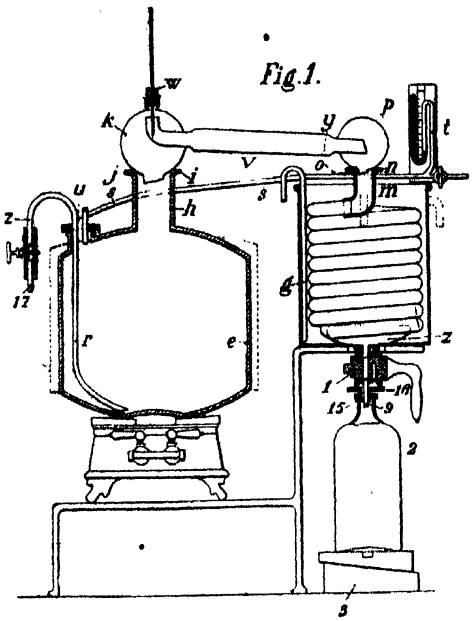
IN the apparatus described by the author in Fr. Pat. 315,978 of 1901, and in the addition thereto of 1902 (this J. 1903, 768), the ascent of the liquid in the tubes known as "grimpage" has been found to work well in the earlier stages of a multiple effect system. It is different, however, with the later stages, in which, owing to the high vacuum and consequent low density of the vapour and high relative density of the liquid, and its viscosity, the "grimpage" only takes place partially. This defect is obviated in the apparatus described in the present specification by causing a mixture of liquid and vapour to flow down instead of up the tubes. An effect, which the author calls "descendage," is obtained, and the liquid passes down in a thin film on the sides of the tubes. A number of long tubes is arranged vertically in concentric rings in a heating jacket, and the liquid enters the outer ring of tubes from below. It passes upwards, and is partially vaporised, and on reaching the top, the mixture of vapour and liquid descends through the inner tubes to the bottom, where the separator is placed, instead of at the top as formerly. The mixture enters a "centrifugal separator," where the vapour is separated from the liquid, which is drawn off from below, while the vapour is conducted by another opening to the vacuum condenser. —W. H. C.

Evaporator; Single effect —— with auto-condensation by continuous compression of the vapour. C. L. Prache and C. G. V. Bouillon. Fr. Pat. 364,408, March 19, 1906.

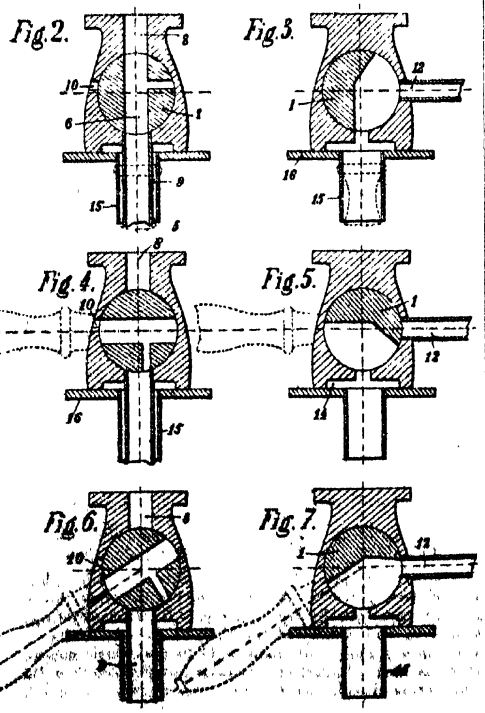
A CYLINDRICAL vessel has its lower part divided into several separate compartments, through which the liquid flows in succession. Each compartment is formed of a number of vertical evaporator tubes grouped round a larger, central return tube, under which there is a deflecting plate. The tubes pass through and are held in position by upper and lower tube-plates, which are common to all the divisions. The liquid flows up the evaporator tubes, and returns by the central tube, from the centre of which, about half-way down, a somewhat smaller tube conveys a portion of the concentrated liquid into the bottom chamber of the next compartment. The vapour given off collects in the upper part of the cylinder, which is common to all the compartments, and it is drawn off by a rotary compressor and returned, after its temperature has been raised by compression, to the space around the tubes, which forms a common heating chamber. The liquid is fed through a special float valve, and tubes are provided to conduct away the finished liquid and the uncondensed gases separately.—W. H. C.

Cold for industrial purposes; Process for the production of ——, by the use of volatile liquids such as ammonia, and the recovery of such liquids. R. A. Grimoin-Sanson. Fr. Pat. 363,978, March 8, 1906.

Two reservoirs for the volatile liquid (ammonia) are each connected on the one hand with a refrigerator-coil, and on the other, with the delivery of an aspirating and compressing pump. The connections are controlled by cocks, actuated by a tappet carried on a rod, which is from time to time moved backwards and forwards by mechanism worked from the piston rod of the pump. Starting with one of the reservoirs full and the other empty, the pump aspirates a charge of ammonia from the first reservoir into the refrigerator-coil, where it is expanded, and does work in cooling the space round the coil. The pump then compresses the charge, and delivers it into the second reservoir. After a certain number of strokes, the first reservoir is emptied, and the second filled with liquid; then the rod carrying the tappet moves, and the cocks are reversed so that the pump now draws from the second reservoir and delivers into the first. This cycle is repeated so long as it is desired to work the apparatus, which is provided with a valve to regulate the rate of flow of the ammonia into the coil.—W. H. C.



Liquid separator; Centrifugal ——. G. de Laval and E. E. F. Fagerström. Fr. Pat. 364,385, March 17, 1906.



SEE Eng. Pat. 5859 of 1906; this J., 1906, 554.—T. F. B.

Vacuum distilling apparatus, with automatic cut-off. J. Robert. Fr. Pat. 364,491, March 22, 1906.

THE apparatus claimed, Fig. 1, consists of a still, *e*, and a condenser, *g*, which are connected by two glass globes, *k*, and *p*, resting in the cups, *i*, and *n*, of the bronze castings, *h*, and *m*, and connected together by the glass tube, *v*. The joints, *j*, and *o*, are made tight by cork rings smeared with vaseline. Liquid may be added to or taken from the still during distillation by the pipe, *r*, and the still is

connected to a vacuum-gauge, *t*, by the pipe, *s*. Thermometers are inserted at *u* and *w*. The condenser, *g*, terminates in a reservoir, *z*, for use during the change of receivers, 2, to which it is connected by a special tap, 1.

This tap is shown in detail in Figs. 2—7; 2, 4, and 6 being sections through one plane and showing the connection between the coil, the receiver, and the atmosphere, and 3, 5, and 7 being sections in another plane and showing the connection between the receiver and the vacuum pump. During the progress of the distillation the plug of the tap is in the position shown in Figs. 2 and 3; 8 being the connection to the coil; 9 to the receiver; and 12 to the pump through the annular space between the tubes, 9 and 15. The joint between the receiver, 2, and the flange, 16, is made by a rubber ring.

When it is desired to change the receiver, the tap, 1, is turned into the position indicated in Figs. 4 and 5, when the connections to the coil and to the vacuum, 12, are closed and the receiver, 2, is in communication with the air through 10. The vacuum in 2 is broken and the latter can be removed and replaced by a fresh receiver. The liquid distilling during the time occupied in the change, which is only a few seconds, collects in *z*. When the fresh receiver is in position, the tap is turned into the position shown in Figs. 6 and 7, when the receiver is cut off from both the coil at 8, and from the air at 10, but is in communication with the pump through 12. As soon as the receiver, 2, is exhausted the tap is turned into the first position (Figs. 2 and 3), and the distillate is once more collected in the receiver, 2. When it is necessary to withdraw a portion of liquid from the still, *e*, during distillation, the apparatus shown in Fig. 8 is used. It consists of two concentric tubes, 17 and 18, which pass through a cork, 20, which is placed in the neck of a suitable vessel. It is connected by 17 to the tube, *r*, and by 19 to the pump. When it is exhausted the tap, 1, is turned into the position shown in Figs. 4 and 5, and the tap, *z*, is opened. The progress of the distillation is watched in the glass globe, *p*, and as there are always a few drops of liquid at the point, *y*, in the tube, *v*, any discoloration due to spurting can be at once seen.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 843.)

Coal production of the world. Eng. and Mining J., Sept. 1, 1906. [T.R.]

THE increase in coal production is steady in most of the world's fields. The production given in the following table is taken from statistics compiled for "The Mineral Industry":—

Countries.	1904.	1905.
	Metric tons.	
Asia:		
India	7,682,310	7,921,000
Japan	11,600,000	11,895,000
Australasia:		
New South Wales	6,116,126	6,035,250
New Zealand	1,562,442	1,415,000
Other parts of Australia	769,723	805,000
Europe:		
Austria Hungary	40,334,681	40,725,000
Belgium	23,380,025	21,844,200
France	34,502,289	36,048,264
Germany	169,448,272	173,663,774
Italy	359,456	307,500
Russia	19,316,000	17,120,000
Spain	3,123,540	3,199,911
Sweden	320,984	331,509
United Kingdom	236,147,125	239,885,228
North America:		
Canada—		
Western	2,619,816	3,133,000
Eastern	4,194,939	4,775,802
United States	318,275,939	352,994,410
South Africa	3,615,000	3,215,000
All other countries	4,250,000	4,550,000
Total	867,020,658	929,622,643

In most cases these reports are from official sources; in others they are estimated as closely as possible from shipping returns and other data.

Oxygen containing hydrogen; Influence of —— in determining calorific values [of fuels]. E. Graefe. J. Gasbeleucht, 1906, **49**, 666—667.

In burning oils of known calorific power in oxygen to which hydrogen has been added, higher calorific values were obtained, the increase depending on the quantity of hydrogen used. Thus, with an oil yielding 10,020 calories, the addition of 1 per cent. of hydrogen brought about an increase of 107 cals.; 2 per cent. a further rise of 309 cals.; and 3 per cent., 523 cals. It was found that, on an average, 1 per cent. of hydrogen raised the calorific value by 180 calories, equal to 1·8 per cent.—D. B.

Non-luminous flames coloured by metal salts; Temperatures of ——. F. Kurlbaum and G. Schulze. Ber. Deutsch. physik. Ges., 1906, **4**, 239—247. Chem. Centr., 1906, **2**, 486.

The radiation from a black body behind a small number of thin, luminous strata of the same temperature, is exactly the same as it would be if such luminous strata were absent. The authors measured the temperature of spirit, Bunsen and hydrogen flames (between the outer edge and the cone) rendered luminous by different salts, by so adjusting the temperature of a Nernst electrode (by regulating the current), that its radiation was not modified on passing through the coloured flame. In the case of sodium salts, the effect is influenced by the nature of the acid radical. Different salts give different temperatures for the same flame, *e.g.*, from 1409° C. for sodium carbonate, up to 1476° C. for thallium chloride, in the spirit flame; from 1660° C. for sodium carbonate, up to 1812° C. for rubidium chloride, in the Bunsen flame; and from 1844° C. for lithium chloride, up to 1954° C. for potassium chloride (blue line) in the hydrogen flame. The temperature rises on passing from longer to shorter wave lengths; the temperature measured with a given spectrum-line of one salt rises on addition of a second salt, the increase being more the greater the difference between the wave-lengths of the rays from the two salts. A similar effect is observed in the case of two spectrum-lines of one and the same salt. The actual temperature of the flame is lowered by the introduction of salts. Salts which give the highest temperatures are those which are the more strongly ionised.—A. S.

Tungsten [Incandescence electric] lamp. F. Uppenborn. J. Gasbeleucht., 1906, **49**, 756—759.

The tungsten-filament incandescent lamp, which is now being placed upon the market by a number of firms, using various methods of manufacture, is the newest of the metallic-filament lamps. Its efficiency is high, varying from about 1·0 to 1·2 watts per Hefner candle (1 Hefner candle = 0·88 English standard candle), and it is claimed that the average life of the lamps is over 1000 hours, no substantial change in the lighting power occurring during that period. The author has compared the tungsten-filament lamp with the carbon-, tantalum-, and osmium-filament lamps, to ascertain their behaviour under variations in the voltage of the current used. The lamps were all designed for 110 volts, and their efficiencies at the start, stated in watts per Hefner candle, were as follows:—carbon filament, 3·53; tantalum filament, 1·61; osmium filament, 1·76; tungsten filament, 1·00. The voltages during the test were caused to vary over a wide range, photometric tests and measurements of the current being made at various points. It was found that the tungsten lamp was, comparatively, very insensitive to alterations in the voltage, the consumption of current increasing but slightly with increase of voltage. By means of this lamp, it is stated, electric lighting is so much cheapened that it can compete more favourably than hitherto with gas lighting.—H. B.

Alkali, &c., works; Forty-second annual report on ——, by the Chief Inspector. VII., page 881.

Erratum.

This J., 1906, page 803, col. 1, l. 26 from bottom: *for* "(2348°)" *read* "(2348° C.)"; also l. 24 from bottom: *for* "1819°" *read* "1819° C."

English Patents.

[Fuel] Briquettes; Manufacture of ——. Lord Armstrong, Rothbury, Northumberland. Eng. Pat. 19,212, Sept. 22, 1905.

"Brewers' bottoms," i.e., the liquid found at the bottom of casks returned by publicans to the breweries, is evaporated to the consistency of treacle, and then, whilst hot, is mixed with small coal, and moulded as usual. The briquettes obtained may be given any convenient coating to make them waterproof, if desired. Or else, ingredients may be mixed with the syrup before the briquettes are made, to make them waterproof throughout. Thus, 1 lb. of resin may be dissolved in ½ oz. of linseed oil foots, and this added to 9 or 10 lb. of the syrup. A good but expensive mixture is obtained by mixing 8 to 10 lb. of the syrup, 9 lb. of resin, 1 lb. of linseed foots, and 2 lb. of glucose.—A. G. L.

Fuel; Artificial ——, and method of making the same. W. P. Thompson, London. From A. Engle, Metz and T. Cahill, Stuart, Iowa, U.S.A. Eng. Pat. 21,644, Oct. 24, 1905.

See Fr. Pat. 358,831 of 1905; this J., 1906, 308.—T. F. B.

Furnaces for burning pulverulent fuel and for treating pulverulent ores. A. M. Robeson, Johannesburg, and C. A. Bettington, Boston, U.S.A. Eng. Pat. 16,226, Aug. 9, 1905.

See U.S. Pats. 817,989 and 817,990 of 1906; this J., 1906, 465.—T. F. B.

Retort ovens; Vertical ——. J. Bueb, Dessau, Germany. Eng. Pat. 16,579, Aug. 15, 1905.

See Fr. Pat. 356,974 of 1905; this J., 1906, 11.—T. F. B.

Furnaces for vertical gas retorts. E. Derval, Paris. Eng. Pat. 2040, Jan. 26, 1906.

See Fr. Pat. 362,501 of 1906; this J., 1906, 747.—T. F. B.

Gas for illuminating and heating purposes; Apparatus for producing —— from petrol or other suitable spirit or oil. B. K. Green and H. Mieville, Great Malvern. Eng. Pat. 26,847, Dec. 23, 1905.

A current of warm, dry air is divided into two portions, and the main stream is blown through a carburetter, charged with petrol, and provided with transverse wick-like screens, which dip into the petrol. The latter is kept at a constant level by means of a ball-float device. A number of perforated pipes is arranged along the bottom of the carburetter and immersed in the petrol; through these pipes the second portion of the air supply is blown, producing a spray of petrol, which falls partly upon the transverse screens. The bell of the gas-holder, in which the carburetted air is stored, operates the valve controlling the air supply, so that the gas production varies automatically with the consumption.—H. B.

Carbides for acetylene lamps, generators, and the like; Prepared ——. Sir C. S. Forbes, Bart., London. Eng. Pat. 16,298, Aug. 10, 1905.

The carbide to be treated is placed under vacuum in an air-tight vessel, and a suitable retarding solution (preferably a solution of resin in petroleum) is then run in, the impregnated carbide being subsequently removed. —H. B.

Explosive fluids or fluids under pressure [Acetylene]; Means for storing ——. C. Hubert, New York. Eng. Pat. 20,079, Oct. 4, 1905.

The explosive fluid (acetylene) is stored in a cylinder filled with finely-granulated, compressed cocoa-nut shell charcoal. The cylinder is closed by a conical plug valve, which has a delivery pipe, a narrow duct or passage

through the plug leading to a fixed pressure gauge, and a relief duct leading to a chamber closed by a screw cap, with a thin central portion that will give way if a dangerous pressure occurs within the cylinder. The valve is actuated by a worm-wheel, and has a filter chamber, filled with cotton, on the duct leading to the interior of the cylinder. A number of fusible metal plugs are inserted in various parts of the cylinder, which will melt, and give relief to the pressure if the contents become dangerously heated.—W. H. C.

Mantles; Method of producing incandescent ——. H. C. Albrecht, Berlin. Eng. Pat. 15,295, July 5, 1906.

Fabrics are impregnated as usual with a solution of the nitrates of thorium and cerium, then dried, impregnated with hydrogen peroxide, dried, and finally burned off. The hydrogen peroxide converts the thorium salt into hydroxide, and it is stated that the finished mantle contains thorium in a higher degree of oxidation than thorium dioxide, ThO_2 (see this J., 1906, 840).—H. B.

Filaments for incandescent lamps. S. Iseki, Kanagawa-Ken, Japan. Eng. Pat. 3509, Feb. 13, 1906.

A carbon filament is coated with tungsten, by depositing the metal from tungsten chloride vapour "according to the process used for making ordinary carbon filaments." The coated filament is then fixed in an exhausted bulb. It is stated that on starting the current, the metal combines with any oxygen remaining in the bulb, forming a hard, protective shield about the filament, and producing a more perfect vacuum.—H. B.

United States Patents.

Briquettes; Process for preparing a mass for making ——. B. Wagner, Berlin. U.S. Pat. 829,042, Aug. 21, 1906.

See Fr. Pat. 350,579 of 1905; this J., 1905, 794.—T.F.B.

Briquettes; Apparatus for coking ——. B. Wagner, Berlin. U.S. Pat. 829,448, Aug. 28, 1906.

See Fr. Pat. 350,536 of 1905; this J., 1905, 721.—T.F.B.

Gas producers; Process of regulating the temperature of combustion in ——. H. L. Doherty, Madison, Wis., Assignor to Combustion Utilities Co., New York. U.S. Pat. 829,105, Aug. 21, 1906.

The claim is for the process of making producer-gas by passing a current of gas consisting of free oxygen or air mixed with from 5 to 15 per cent. of carbon dioxide through a deep bed of fuel, and conducting the resulting gas, unburnt, to the place where it is to be used. The percentage of carbon dioxide is adjusted in such manner that the heat-producing or exothermic reaction, $C+O=CO_2$, and the heat-absorbing or endothermic reaction, $CO_2+C=2CO$, are so balanced, that the resulting temperature is sufficiently high to completely burn the fuel to an ash, but not high enough to allow of the formation of troublesome clinkers.—W. H. C.

Gas producer. J. G. Nash, Adelaide. U.S. Pat. 829,541, Aug. 28, 1906.

See Eng. Pat. 17,712 of 1904; this J., 1904, 1081.—T.F.B.

Gas; Apparatus for producing power ——. L. Hertzog, Berlin-Südende, Assignor to A. Saurer, Arbon, Switzerland. U.S. Pat. 829,919, Aug. 28, 1906.

See Fr. Pat. 346,526 of 1904; this J., 1905, 191.—T.F.B.

Gases; Apparatus for subjecting —— to the action of liquids. W. Feld, Hönningen on Rhine, Germany. U.S. Pat. 829,261, Aug. 21, 1906.

See Fr. Pat. 360,373 of 1905; this J., 1906, 107.—T.F.B.

Gas purifying apparatus. M. Dross, Aplerbeck, Germany. U.S. Pat. 829,700, Aug. 28, 1906.

See Eng. Pat. 1228 of 1905; this J., 1906, 212.—T.F.B.

Electrode for arc-lights. F. J. Gerard, Assignor to L. Fiedler, London. U.S. Pat. 828,544, Aug. 14, 1906.

The electrode is composed of an intimate mixture of carbon and an alloy of magnesium with aluminium or another metal, to which may be added a small percentage of cerium nitrate, or a salt of a rare earth.—W. H. C.

French Patents.

Gas-retort furnace. P. V. Parsy. First Addition, dated March 10, 1906, to Fr. Pat. 360,070, Feb. 11, 1905 (this J., 1906, 466).

The retort setting described in the principal patent is provided centrally with a generator and recuperator, placed end to end, parallel with the retorts, so as to occupy the entire depth of the setting, and having their gas-distributing outlets at the top.—H. B.

Producer for coal slack, &c. Maschinenfab. und Mühlenbauans. G. Luther A.-G. Fr. Pat. 364,116, Feb. 21, 1906.

The producer, which is designed for utilising coal-slack and other finely-divided combustibles, is provided internally with two or more horizontally superposed series of baffles, which support the fuel to a considerable extent, and prevent the obstruction due to the pressure of the superincumbent mass. Preferably there are two series of baffles, the tops of which are Λ-shaped, the air supply being admitted beneath those of the upper series, which are perforated, whilst the gas produced is drawn off beneath the lower series.—H. B.

Gas; Process of carburetting ——. [*Carburetted water-gas*]. F. Dannert. Fr. Pat. 364,210. March 13, 1906.

A producer, which is charged with solid fuel, and is provided as usual with a gas outlet at the top and steam and air inlets at the bottom, is also fitted at one side with a vertical channel or pipe in the masonry, the lower end of which opens into the reducing zone of the fuel, whilst the upper end is fitted with a siphon tube for the admission of liquid hydrocarbon. The oil becomes vaporised on dropping down the channel, and on issuing into the reducing zone is converted completely into incondensable gas, without undergoing combustion.—H. B.

Filaments for incandescence electric lamps. Soc. Zirkon-Glühlampenwerk, Dr. Hollefreund & Co. Fr. Pat. 364,181, Jan 30, 1906.

"Hydrogenised" and "nitrogenised" compounds of chromium, molybdenum, tungsten, and other metals of the iron group may be obtained by proceeding, according to Fr. Pat. 342,581 of 1904 (this J., 1904, 942), the magnesium, aluminium, potassium, or sodium formerly used as reducing metal being replaced by powdered zinc, or some other metal which does not react violently with oxidised compounds. Or, the four above-named metals may be used safely for the reduction, if they are employed in large excess (say five times the amount theoretically required). The reduction may also be effected in two stages: first with zinc powder, and then with magnesium, &c. In any case, the pulverulent product is purified with acids, dried, mixed with an agglutinant such as tar, and formed into threads. The filaments are then heated at 1000°—1500° C. in an indifferent gas for several hours; or, preferably, they are kept incandescent by means of a strong electric current for several hours in an atmosphere of nitrogen at 180 mm. pressure. In the latter case they become denser, and ultimately yield nitrogenised filaments of very high efficiency.—H. B.

Filaments for incandescence lamps. A. Just and F. Hanaman. Fifth Addition, dated Feb. 19, 1906, to Fr. Pat. 347,661, Nov. 4, 1904 (this J., 1905, 431 and 1220).

In making a filament of tungsten or molybdenum, the process described in the principal patent (wherein the metal is first deposited upon a core of carbon) is modified by constructing the core of carbon and tungsten or molybdenum, instead of carbon only. The filament, whether made of carbon, or of carbon *plus* metal, is then

coated with metal, and heated to a high temperature under reduced pressure, in an atmosphere of hydrogen containing a small proportion of an oxidising gas, such as steam. This modification of the process expedites the elimination of the carbon.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 843.)

Fuels; Decomposition of solid —— at gradually increasing temperatures. E. Börnstein. J. Gasbeleucht, 1906, **49**, 627—630, 648—652, 667—671.

SPECIMENS of wood, peat, lignite, and coal were each subjected to fractional distillation, the temperature being kept constant at certain points until the decomposition at such temperature was complete, the highest temperature in the experiments being 450° C. The distillations were effected in an iron retort fitted with a Liebig's condenser, the distillates being collected in a series of U-tubes and towers for the retention of tarry products, whilst the sulphur compounds were absorbed in tubes containing anhydrous copper sulphate.

One kilo. of fir wood containing carbon, 48·75; hydrogen, 6·48; nitrogen, 0·63; oxygen, 40·75; sulphur, 0·08; water, 3·21; and ash 0·10 per cent., gave the following results:—

Temp.	Water.	Tar.	Gas.	Sulphur compounds.
	grms.	grms.	litres.	grms.
250° C.	65·0	—	6·1	
250—300° C.	65·3	4·9	11·1	
300—350° C.	145·7	32·3	41·0	1·3
350—400° C.	71·2	24·0	29·2	
400—450° C.	20·9	20·6	29·2	

Composition of the gas:—

Temp.	CO_2.	Heavy hydrocarbons.	CO.	H.	CH_4.
300—350° C.	53·5	0·2	27·7	3·7	14·9
350—400° C.	55·0	1·5	32·6	3·0	7·9
400—450° C.	28·0	5·0	29·0	17·3	20·6

One kilo of peat containing carbon, 43·76; hydrogen, 4·16; nitrogen, 2·30; oxygen, 24·57; sulphur, 0·24; water, 17·03; and ash, 7·94 per cent., gave:—

Temp.	Water.	Tar	Gas	Sulphur compounds.
	grms.	grms.	litres.	grms.
250° C.	91·1	—	3·0	—
250—300° C.	56·4	traces	4·6	—
300—350° C.	173·7	2·5	11·4	—
350—400° C.	44·1	9·6	33·2	2·0
400—450° C.	42·5	31·2	42·0	

Composition of the gas:—

Temp.	CO_2.	Heavy hydrocarbons.	CO.	H.	CH_4.
300—350° C.	89·2	0·3	10·1	0·3	—
350—400° C.	62·3	0·4	7·2	3·1	25·5
400—450° C.	55·4	3·7	12·3	3·1	25·4

One kilo. of Bohemian lignite containing carbon, 63·94; hydrogen, 5·05; nitrogen, 0·83; oxygen, 21·70; sulphur, 0·45; water, 1·81; and ash, 6·22 per cent., gave:—

Temp.	Water.	Tar.	Gas.	Sulphur compounds.
	grms.	grms.	litres.	grms.
250° C.	55·6	—	1·9	—
250—300° C.	44·9	—	3·3	—
300—350° C.	50·4	0·9	8·1	0·7
350—400° C.	36·5	8·3	16·7	0·5
400—450° C.	40·5e	34·9	29·5	0·4

Composition of the gas:—

Temp.	CO_2.	Heavy hydrocarbons.	CO.	H.	CH_4.
300° C.	91·4	0·7	6·4	0·3	1·1
300—350° C.	90·9	1·0	7·6	0·5	—
350—400° C.	69·6	2·5	15·8	8·8	3·2
400—450° C.	47·8	3·9	15·1	11·9	21·2

The experiments with different kinds of coal have already been referred to in previous communications (this J., 1906, 213 and 583).—D. B.

Petroleums of North America; A comparison of the character of those of the older and newer fields. C. Richardson. J. Franklin Inst., 1906, **162**, 57—70, 81—128.

THE author has collected the results obtained in the examination of American petroleums, and compares the oils from the older and newer fields. The subject is treated under the following headings:—Development of petroleum as an industrial product in North America; character of the petroleums of North America; Appalachian field, Ohio-Indiana field, Canadian field, Colorado field, Wyoming field, California field, Texas field, other fields, Kansas field, Louisiana field, Alaska field, Cuban field, Mexican field; Comparison of North American petroleums.—A. S.

Asphaltum industry of the United States. U.S. Geol. Survey. Oil, Paint, and Drug Rep., Aug. 13, 1906. [T.R.]

THE output of bituminous sandstone has decreased from 46,641 short tons, valued at $138,465, in 1904, to 39,273 short tons, valued at $94,972, in 1905. More than 90 per cent. of the bituminous sandstone produced in the United States is quarried in California, and the decrease in production and value was probably due to the keen competition of the "oil asphaltum" of the same State.

The production of bituminous limestone, which is practically confined to the State of Kentucky, increased from 1798 short tons ($4495) in 1904 to 6029 short tons ($42,000) in 1905. The marked increase of price in 1905 has not been explained. The production of mastic from Kentucky bituminous sandstone increased from 1200 short tons ($10,800) in 1904 to 2200 short tons ($22,000) in 1905.

Hard and refined or gum asphaltum decreased in production from 6637 short tons, valued at $141,446, in 1904, to 3036 short tons, valued at $41,438, in 1905. During 1905 the hard natural asphaltum of California brought $12.07 per short ton at the mines, whilst that of the Indian Territory brought $15. The more valuable grahamite, important veins of which are known in the Indian Territory, was not produced at all in 1905, on account of litigation over the ownership of the property.

The production of natural liquid asphaltum, or maltha, which is confined to California, decreased from 3363 short tons, valued at $36,320, in 1904, to 3139 short tons, valued at $34,292, in 1905.

The production of wurtzilite decreased from 550 short tons, valued at $50,000, in 1904, to 500 short tons, valued at $44,000, in 1905.

The production of gilsonite increased from 2978 short tons in 1904 to 10,916 short tons in 1905. The value increased from $14,175 in 1904 to $47,900 in 1905, but the average price per short ton decreased from $4.76 in 1904 to $4.31 in 1905.

The production of "oil asphaltum" has increased from 44,405 short tons, valued at $459,135, to 50,169 short

tons, valued at $430,911. If, however, the 1300 short tons of road oil (a liquid oil asphaltum), valued at $1495, be eliminated from the oil asphaltum, there will remain 48,869 short tons of hard or "D" grade oil asphaltum, valued at $429,416, giving an average value of $8.78 per short ton. The production of oil asphaltum is an industry peculiar to California, and most of the material is made as a by-product in the distilling of lubricating and illuminating oils and lighter products from crude petroleum of asphaltic base.

Exports.—During the fiscal year ending June, 1905, asphaltum and manufactures of asphaltic material to the value of $291,120 were exported from the United States to other countries. The most important receivers of these products were in the order named:—Brazil, United Kingdom, Canada, Germany, Chile, Mexico, and Argentina. The chief features of the trade were the opening of important markets in Mexico and the three South American countries named, a marked increase of exports to the United Kingdom, and decrease, as compared with 1904, of more than 36 per cent. in the value of exports to Canada. The total value of the exports for the fiscal year ending June 30, 1904, amounted to $160,186.

The imports of crude asphaltum in 1905 amounted to 109,596 short tons, valued at $479,296, as compared with 133,941 short tons, valued at $590,890, in 1904. About two-thirds of the asphaltum which is imported into the United States from foreign countries comes from the Island of Trinidad, off the coast of Venezuela. Other important sources are Bermudez (Venezuela), Cuba, and Italy.

Mould fungus capable of decomposing paraffin wax. O. Rahn. Centralbl. Bakt., 1906, [II.], 16, 382; Z. ges. Brauw., 1906, 29, 478.

The organism in question, a species of *Penicillium*, was found to decompose two kinds of paraffin wax to the extent of 77—79 per cent., when the experiments were conducted on a large scale, the mycelium then containing a light brown colouring substance, soluble in alcohol, that did not appear when only small quantities of the paraffin were present. The same phenomenon had been previously observed in the case of mould fungi that decompose fats. On ordinary nutrient media the same *Penicillium* forms a white, luxuriant growth; in gelatin it forms numerous small crystals producing turbidity. It also grows well on palm oil agar-agar, but not on the same fat in presence of mineral salts of ammonium, though in a solution of ammonium salts and stearic acid it grows with vigour, and forms very thin coremia, 3 cm. in length. It does not decompose yellow vaseline, and grows but sparsely on white vaseline. On paraffin wax it forms large, white, dished growths, the edges of the floating mycelium thrusting themselves up into the air.—C. S.

Alkali, &c., works; Forty-second annual report on ——, by the Chief Inspector. VII., page 881.

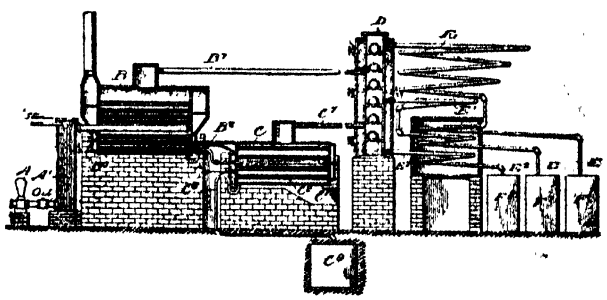
English Patents.

Waste heat in coke; Utilisation of ——. A. Waddell, Dunfermline, and F. Waddell, South Queensferry. Eng. Pat. 18,216, Sept. 9, 1905.

The hot coke is drawn from the ovens or retorts into a vessel, open at the top, and supported on a carriage. It is then wheeled under a cover, which is allowed to rest on the vessel so that a tight joint is formed. Ammoniacal liquor is then run on to the hot coke through a pipe which passes through the cover, and the steam and ammonia given off are conveyed by another pipe, which also passes through the cover, to a still, where their heat is utilised to distil off the ammonia from a further quantity of liquor.—W. H. C.

Coke from fuel containing a large proportion of water, such as peat, lignite, and the like; Method of and apparatus for producing ——. W. Wielandt, Zwischenahn, and Torfkoks, G.m.b.H., Berlin. Eng. Pat. 968, Jan. 13, 1906.

The vapours or gases generated by the material in the coke oven are drawn off from the colder upper zone, through suction pipes, either apart from the gaseous distillation products formed in the coking zone, or after being drawn through the latter zone. Means are provided for varying the level at which the suction takes place, so as to modify the extent of the zone influenced by the suction-pipe removing the distillation products, and to form a neutral zone from which the gases and vapours separate in opposite directions.—C. S.



United States Patents.

Coking-oven [for peat]. H. J. Wickham, Manchester, and F. C. Rockwell and W. L. Shepard, Hartford, Conn. U.S. Pat. 827,707, Aug. 7, 1906.

The coking-oven consists of a vertical, cylindrical chamber, closed at the upper end, and having a screen extending across it, near the open lower end. Below the oven is a circular base-plate, the outer edge of which is turned first downwards and then upwards, forming an annular trough in which the lower open end of the coking-oven rests.—A. S.

Distillation apparatus [Oils, &c.]; Automatic and continuous film ——. F. J. Clemenger, Beaumont, Tex. U.S. Pat. 829,258, Aug. 21, 1906.

The oil, or other liquid to be distilled, is fed by the pump, A, through a "comminuter," A^1, and delivered as a film

upon the flues, B^3, of the primary heating chamber, B. The residual oil from B, flows by the trapped pipe, B^6, on to the flues, C^2, of the secondary heating chamber, C. The residual oil flows from the chamber, C, by the pipe, C^6, into the reservoir, C^9. The chamber, C, is heated by the furnace, C^1, the gases from which pass on and heat the other chamber, B. The vapours given off in each chamber are conducted by separate pipes, B^7, C^7, to an air-jacketed separator, D, provided with air cooling pipes and with superposed "resisting plates." From the separator the vapours are conducted by separate pipes, E, E^1, E^2, placed at different heights to the receivers, F, F^1, F^2.—W. H. C.

French Patent.

Mineral oils; Process and apparatus for refining ——. The Alcohol Syndicate, Ltd. First Addition, dated Nov. 30, 1905, to Fr. Pat. 325,836, Oct. 21, 1902.

See Eng. Pat. 28,243 of 1904; this J., 1905, 1294.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 844.)

Fluorescence: Theory of ——. G. Woker. J. of Physical Chem., 1906, **10**, 370—391. Chem. Centr., 1906, **2**, 485—486.

It is known that fluorescence and colour often occur simultaneously, and the author has found that fluorescent solutions lose their fluorescence on addition of a dyestuff: for instance, quinine sulphate solution on addition of picric acid, and petroleum on addition of methyl orange. The following explanation of these facts is offered. The fluorescence of a substance can be diminished or destroyed by a complementary colour. Visible fluorescence is diminished by the introduction of chromophor groups into the molecule, because the absorption bands are thereby displaced towards the red end of the spectrum, and the possibility of fluorescence is thus lessened. Salt-forming groups usually have a similar effect, and indeed greater, the nearer they are to the chromophor groups. The latent fluorescence that all benzene derivatives possess can be rendered visible by the same means that diminish visible fluorescence, *viz.*, by the introduction of chromophor and salt-forming groups, especially by the introduction of two phenol residues in ortho positions with respect to one another.—A. S.

United States Patent.

Dyestuff; Bordeaux-red sulphur [*Sulphide*] ——, *and process of making same.* A. Schmidt, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pat. 829,740, Aug. 28, 1906.

See Eng. Pat. 14,543 of 1905, this J., 1906, 260.—T. F. B.

French Patents.

Dyestuffs; Process of making concentrated liquid solutions or easily liquifiable pastes from sulphide ——. Farbwerke vorm. Meister, Lucius, and Brüning. Fr. Pat. 361,481, May 17, 1905.

See Eng. Pat. 9883 of 1905, this J., 1906, 584.—T. F. B.

Dyestuffs; Process of making yellow sulphide ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,502, May 23, 1905.

See Eng. Pat. 27,292 of 1904; this J., 1905, 1167.—T. F. B.

German Patents.

Dyestuffs; Process for preparing blue-black monoazo ——. Act.-Ges. f. Anilinfabr. Ger. Pat. 169,826, Oct. 14, 1904.

Blue-black dyestuffs are produced by combining diazotised 2.8-aminonaphthol-3.6-disulphonic acid with the acidyl compounds of diaminocresol ethers ($CH_3:NH_2:OCH_3:NH_2 = 1:2:4:5$), or of *p*-amino-*o*-anisidine, and removing the acidyl groups from the resulting dyestuffs; the same dyestuffs are also obtained by combining the diazotised aminonaphtholsulphonic acid with nitro-aminocresol ethers ($CH_3:NH_2:OCH_3:NO_2 = 1:2:4:5$) or with *p*-nitro-*o*-anisidine, and then reducing the nitro-group by an alkaline reducing agent. These dyestuffs are said to be faster to light and of better shade than those derived from *p*-nitraniline or *p*-nitro-*o*-toluidine and 1.4-nitronaphthylamine.—T. F. B.

Dyestuffs; Process for preparing red or bluish-red monoazo —— susceptible to chroming. Anilinfarben- und Extrakt-Fabr. vorm. J. R. Geigy. Ger. Pat. 168,128, March 4, 1905. Addition to Ger. Pat. 165,743, July 9, 1904.

Instead of combining 1-phenyl-3-methyl-5-pyrazolone with 1-diazo-2-hydroxynaphthalene-4-sulphonic acid or its nitro-derivatives, as in the principal patent (see Eng. Pat. 17,274 of 1904; this J., 1905, 725), the following diazo-compounds may be used:—1-Diazo-2-hydroxynaphthalene-6- or -7-sulphonic acid, 2-diazo-1-hydroxynaphthalene-4- or -5-sulphonic acid; 1-diazo-2-hydroxynaphthalene-3.6-, 4.6-, or 4.7-disulphonic acids, or 2-diazo-1-hydroxynaphthalene-3.6-, 4.7-, or 4.8-disulphonic acid, or the anhydrides of any of these. Combination takes place best in presence of alkali hydroxide. As a rule, the *a*-naphthol derivatives are brown, and the *β*-naphthol derivatives orange, becoming red and bluish-red after chroming. The dyestuffs produce cochineal-coloured aluminium lakes, and are all capable of dyeing on chromed wool.—T. F. B.

Dyestuff: Process for preparing a monoazo —— susceptible to chroming. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 168,610, March 14, 1905.

Diazotised *p*-chloro-*o*-aminophenol is combined with 1.8.3.6-dihydroxynaphthalene-disulphonic acid in presence of excess of alkali hydroxide. This dyestuff is characterised by its fastness, and the production of indigo-blue shades on chrome mordants, distinguishing it from the dyestuffs obtained from *p*-chloroaminophenol and 1.8-aminonaphthol-3.6-disulphonic acid on the one hand, or nitro-*p*-chloro-*o*-aminophenol and chromotrope acid on the other hand.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 845.)

Fabrics: Stripping of dyed ——. E. Hibbert. J. Soc. Dyers and Col., 1906, **22**, 276—278.

To ascertain the comparative stripping power of sodium hyposulphite (hydrosulphite) and titanous chloride they were tried, the former in alkaline and the latter in acid solution, on cotton dyed with 2 per cent. of Benzopurpurin 4B. The amount of titanous chloride necessary to destroy the colour was about one-third in excess of that required by theory. With an equivalent amount of hyposulphite only slight reduction took place; with twice the quantity the bulk of the colour was discharged, though a distinct pink shade remained; whilst even with four times the amount, the white was less perfect than that yielded by titanous chloride. A similar result was obtained with cotton dyed with 2 per cent. of Chrysophenine. A disadvantage to the use of titanous salts is that frequently a certain amount of titanic hydroxide is deposited on the fibre, which is not easily removed, and occasions trouble if the fabric is to be subsequently dyed with basic dyestuffs. This difficulty may, however, be overcome by adding potassium oxalate to the discharging bath.—D. B.

English Patents.

Hemp-bast and the like; Process for the manufacture of artificial ——. Vereinigte Kunstseidefabr. A.-G., Kelsterbach a/M., Germany. Eng. Pat. 7520, March 28, 1906. Under Int. Conv., Jan. 2, 1906.

See Fr. Pat. 363,782 of 1906; following these.—T. F. B.

Steaming fibres and fabrics; Process of and apparatus for ——. E. Simon, Villefranche, and J. B. Weckerlin, Lyons, France. Eng. Pat. 2830, Feb. 5, 1906. Under Int. Conv., May 22, 1905.

See Fr. Pat. 355,081 of 1905; this J., 1905, 1226.—T. F. B.

United States Patents.

Textile fabrics; Apparatus for treating [*washing, dyeing, &c.*] ——. W. D. West and V. Mauck, Conshohocken, Pa. U.S. Pat. 823,834, June 19, 1906.

This invention relates to an apparatus for subjecting

textile fabrics to successive operations, such as washing, dyeing, carbonising, &c., without removing the material from the apparatus. The latter consists of a treating tank, which is provided with a perforated drum for carrying the material to be treated. Two conduits connect the interior of the drum and the space between the exterior of the drum, and the inner surface of the treating tank, respectively, with a four-way valve. By means of the valve the direction of the liquid in the conduits may be reversed, so that it may be passed to the interior of the drum or to the outside of the fabric, until both drum and treating tank are filled with liquid. Two supply-conduits lead from the valve, and in one of the conduits is a pressure-regulator, working automatically. A heater, for liquid or air, is placed in a by-pass connected with one of the supply-conduits, and a cooler in a by-pass in the other, valves controlling the passage of fluid through the supply conduits and the by-passes. The supply-conduits are connected to separate chambers in a "manifold," the latter being connected by conduits and a four-way valve to two separate supply tanks. The manifold may have several supply-conduits for introducing compressed air or different liquors.—B. N.

Dry cleaning [Textile fabrics]; Process of ——. J. Doux, Utica, N.Y. U.S. Pat. 828,644, Aug. 14, 1906.

THE material is washed in an alkaline bath composed of benzene and anhydrous ammonia.—B. N.

Wool; Apparatus for the extraction of grease from ——. A. H. Burt, Mosman, H. Jackson and C. A. Finch, Sydney. U.S. Pat. 829,763, Aug. 28, 1906.

FRENCH PATENTS.

Hemp [bast]; Process for producing artificial ——, *by tightly sticking together brilliant threads into the form of a ribbon.* Vereinigte Kunstseidefabriken A.-G. Fr. Pat. 363,782, March 2, 1906.

THIS invention relates to a process for producing ribbons, or continuous thongs of artificial hemp, from silk, artificial silk, or mercerised cotton. A flexible material, or "glue," such as collodion, a solution of cellulose or viscose, &c., is employed to stick together the threads, and produce a continuous ribbon, without knots. By adding to the glue a substance such as powdered chalk, zinc white, &c., the threads may be partially covered, and the lustre removed, this process being carried out either during or after the production of the ribbon. The lustre may also be removed by chemical treatment, a covering substance being precipitated on the threads at the same time that the latter are fixed by the glue. Thus, by using an aqueous solution of viscose, which is not in the "ripe" state, and then afterwards passing the threads through a bath of mineral acid, the threads receive the required suppleness, and have their lustre removed by a precipitate of amorphous sulphur which is formed on the material.—B. N.

Wool on bobbins; Machine for washing ——. J. Ernoult et Cie. First Addition, dated Jan. 26, 1906, to Fr. Pat. 356,277, July 13, 1905 (this J., 1906, 16).

THE title of the main patent should also be interpreted: "Machine for bleaching wool on bobbins."—B. N.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 843.)

FRENCH PATENT.

Dyeing skins; Continuous machine for ——. R. Martinet and A. Dulac. First Addition, dated Jan. 29, 1906, to Fr. Pat. 352,095, Feb. 7, 1905 (this J., 1905, 921).

INSTEAD of an endless band, as described in the main patent, the machine is provided with a rotating circular table, divided into compartments, and intermittently turning a fraction of a circle. The mordant, dye-liquor, &c., are sprayed and distributed as described in the main patent.—B. N.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 847.)

Alkali, &c., works; Forty-second annual report on ——, *by the Chief Inspector.* Proceedings during the year 1905, &c. May 17, 1906. Price 8d.

THE Alkali, &c., Works Bill, 1905, was withdrawn at the end of July, 1905, and has been re-introduced in the present year. The number of alkali works registered in 1905, is 73, the same as in the preceding year, but the (other) scheduled and registered works are 995 as against 967 in the former year. The principal increase in separate processes registered, as distinct from works registered, is under the headings of ammonium sulphate and muriate of ammonia (ammonium chloride). There has been one prosecution, with exaction of penalty and costs, for infraction of the rules respecting the escape of acid gases. Considerable increase of activity took place in the autumn of 1905 in the larger alkali and wet copper works, and in the majority of works full production was carried on.

The nitric acid process for the manufacture of chlorine is no longer in operation. In the Widnes and Runcorn district (No. 3A), in which the Weldon, Deacon, and electrolytic processes for making chlorine and its products are all represented, considerable difficulty arose from escapes of chlorine in the fan draught exits of the bleach chambers, nuisance being caused in the neighbourhood (the volume of gases to be finally dealt with were not less than 100,000 cb. ft. per hour), but the difficulty was met by the use of absorbing plant consisting of pipe towers packed with horizontal earthenware bars of triangular section, and fed with a strong solution of caustic soda, through which the residual gases of the bleach chambers were discharged by means of flues. This system proved so effective as to almost completely free the discharged gases from chlorine.

The active demand for products of the Leblanc process, especially in the latter part of the past year, led to increased production of alkali waste. In several instances the acidity of the chimney gases in works employing this process, showed an increase, and demanded close supervision. Experiments having for their object the lessening of the escape of sulphur in gaseous states of combination in the Claus kiln are still in progress. Mr. Hemingway's suggestion to use ferrous sulphite as an absorbent for residual gases containing sulphuretted hydrogen was subjected to close laboratory investigation, followed by a prolonged series of experiments conducted by the United Alkali Co. The results obtained (shown in tabular form) were, however, not found encouraging. With regard to the employment of ferrous sulphite as an absorbent, it is remarked that "this reagent only makes one journey, not being regenerated during the progress of subsequent reactions." This is because one of the products of the reaction, ferrous thiosulphate, reacts in hot solution to produce iron disulphide, which is inert to further action,

and in cold solution does not appreciably act on sulphuretted hydrogen; and so the "cycle of reactions" breaks down.

In the chamber process for making sulphuric acid, the use of mechanical means for creating the necessary draught has given satisfaction when adopted, especially as local escapes from the burners are thereby more readily avoided. With respect to the replacement of steam by water sprays in the earlier chambers of a series, minute precautions are found necessary to ensure a continuous supply; in the back chambers, steam is found more advantageous than atomised water, on account of the temperature requirements. Reference is made to Inglis's second paper on the loss of nitre in the chamber process, contributed to this Society (this J., 1906, 149—154), wherein it is held that about half of the total loss of nitre is due to incomplete absorption of nitrogen peroxide and trioxide in the Gay-Lussac tower, a view upheld by most of the authorities dealing with the question.

With respect to the "acid mist" occurring in the chambers, Raschig's researches are referred to, according to which the nitroso-sulphonic acid, regarded as formed by the interaction of nitrous and sulphurous acids, is acted upon by a further molecule of the former to produce the newly named "nitrosisulphonic acid," thus: (1), $ON.OH + SO_2 = ON.SO_3H$ (nitroso-sulphonic acid), and (2), $ON.SO_3H + ON.OH = NO + OH.ONSO_3H$ (nitrosisulphonic acid); which latter splits up under the influence of heat into nitric oxide and sulphuric acid ($OH.ONSO_3H = NO + H_2SO_4$), nitrous acid, ON.OH, being regenerated from the nitric oxide by steam and oxygen in the air present in the chamber. This nitrosisulphonic acid (called also peroxylaminesulphonic acid, and known to vitriol makers as "purple acid") occurring fugitively in "chamber drips," is so unstable as to be a difficult subject for investigation; but Raschig's studies have led him to make the suggestion that the addition of nitric acid should be effected in the acid fed upon the Gay-Lussac tower instead of at the usually adopted spot, viz., to the gases in the Glover tower before entering the first chamber. He advises also using some excess of sulphurous acid in the last chamber. The unstable purple acid is thus oxidised into the stable familiar nitro-sulphuric acid, the nitric acid itself being converted into the same compound by the action upon it of such excess of sulphurous acid in solution of strong sulphuric acid as escaped reaction with the nitrous vitriol. (This J., 1905, 923.) The chief inspector suggests certain difficulties attending the practical working of such changes; but sums up the conditions that should regulate the procedure.

For concentrating and rectifying sulphuric acid, the Kessler process continues in favour with the manufacturers as well as with the inspectors.

The number of works engaged in catalytic or contact processes for the manufacture of sulphuric acid remains the same as in the previous year, and generally, somewhat lower figures are recorded as to the acidity of the residual gases, several minor improvements having been made in steadying the operation of the plants.

Chemical manure works are entirely dependent for the manufacture of superphosphate on imported material. The following table gives the amounts imported in tons:—

	1905.	1904.	1903.
Guano	29,223	24,276	28,000
Mineral phosphates ..	421,026	419,221	392,714
Nitrate of soda ..	104,436	120,528	115,000

The exports of sulphate of ammonia in 1904 were 177,280 tons, as against 189,350 tons in 1905; and the estimated home consumption, including use in manure manufacture, was 68,500 tons and 68,000 tons respectively. The large quantities of superphosphate produced in Belgium as a by-product of the spelter industry, and exported to this country, have induced depression of trade, with low prices here.

In sulphate and muriate of ammonia and gas liquor works, in which the "combustion neutralisation" method for dealing with the foul gases is applied (chiefly in large works), a clear effluent, satisfactory to the local authorities, is not always supplied. The effluent is sometimes of a pale green colour, due to reactions on the phenoloid bodies present, and the presence of these bodies and of sulphocyanides (thiocyanates), is supposed to retard bacterial activity in bacterial filter-beds. The matter is of such importance that objections to such effluents, if maintained, might eventuate in discontinuance of the local manufacture of ammonia products. Experiments dealing with the subject have been conducted for some time past, with some success, in the direction of reducing the oxygen-consuming power of the effluent. In one instance, a gas company has adopted a process designed to remove sulphocyanide (thiocyanate) from the spent liquor, and thus to yield a clear colourless effluent. On purification by iron oxide, as usually practised in the smaller works, it is preferred to introduce the foul gases below a conical heap of the oxide, on a concrete floor, by a simple gas-distributing device.

The conditions under which ammonium cyanide is a notable constituent of ammoniacal gas-liquor have been carefully investigated. When hydrocyanic acid is present in the gases from the ammonia saturator, and these gases are passed into contact with iron oxide, some means must be applied to remove the acid. But as ammonium cyanide reacts with polysulphide, with formation of ammonium thiocyanate (sulphocyanide), it is possible to exclude cyanide by maintaining polysulphide always in excess in the liquor sent to the stills. In coke-oven works, owing to the high temperature reached in the ovens, cyanogen is liable to occur in relatively large proportion, and it is urged that, in all such cases, the liquors should be specially treated for removal of cyanides before undergoing distillation. Even in works where the Claus process is in operation on the foul gases, and conversion of hydrocyanic acid into ammonia may be anticipated, a prior removal of cyanide is recommended. E. Linder presents a memorandum on the analysis of ammoniacal liquors from various sources, giving the result of his extensive study of the subject, especially dealing with the presence of cyanogen and its compounds in ammoniacal liquors (results being given in tabular form), and giving methods of analysis, which the chief inspector considers "may now be considered as perfected."

The chief inspector, having made special inquiries of medical authorities as to the effects produced by the absorption of hydrocyanic acid by the blood, is able to state that "hydrocyanic acid forms a compound with hæmoglobin, to which the name cyanmethæmoglobin has been given. The spectrum of this body does not resemble that of carboxyhæmoglobin (the compound formed in cases of carbonic oxide poisoning), but there is frequently found a peculiar bright red colour of the blood and mucous surfaces, which might suggest the peculiar colour of the blood in carbonic oxide poisoning. This characteristic colour is by some observers attributed to the cyanmethæmoglobin itself; by others to the direct effect of hydrocyanic acid interfering with the tissues taking up oxygen from the blood, so that the whole of the blood, both arterial and venous, becomes brightly coloured."

Under the heading of the "Recovery and production of ammonia," the following table is given, showing the amount of sulphate of ammonia produced in the United Kingdom:—

	1905.	1904.	1903.
Gas works	155,957	150,208	149,489
Iron works	20,376	19,568	19,119
Shale works	46,344	42,486	37,353
Coke oven works	30,732	20,848	17,438
Producer gas and carbonising works (bone and coal) ..	15,705	12,880	10,265
Total	269,114	246,990	233,664

The increase under the last sub-heading arises entirely from the operation of producer gas plants, still more of which will, it is stated, be in operation during the current year (1906).

The occurrence of "blue salt" in sulphate of ammonia saturators, in some cases to such an extent as to render the product unsaleable, was the subject of an interchange of views between the inspectors at a staff meeting held by them in October. The discoloration occurs not infrequently in works where sulphate of ammonia is manufactured by the distillation of ammoniacal liquor containing cyanogen compounds, and is attributable to a minute quantity of an oxidisable ferrous ferrocyanide, formed by interaction between ammonium ferrocyanide and iron salts. According to one view, the impurity is due to priming over of the gas liquor containing it from the still. E. Linder, however, in his elaborate investigation of the subject, gives reasons for preferring, as a working hypothesis, that the ammonium ferrocyanide concerned is formed by interaction between ammonium cyanide volatilised from the still, with ferrous oxide or sulphide separated in the saturator through deficiency of acid. As this separation only occurs in a neutral or alkaline liquid, it follows that the "blue salt" should not appear from a saturator in which acid is always maintained in excess. There are three stages to the formation of "blue salt": first, the formation of ammonium ferrocyanide; second, of ferrous ferrocyanide; and lastly, the oxidation of ferrous ferrocyanide to Prussian blue. Experiments on the subject, conducted by Sutton and Linder, at the East Greenwich Works of the South Metropolitan Gas Co., are given in detail. J. W. Young has contributed the following interesting facts in respect to the sporadic appearance of "blue salt" in his district: "Last autumn the larger still and saturator consistently made 'blue salt' for a few days: a most unusual occurrence here. No reason could be given, till, on stopping the plant for examination, an iron stay within the saturator, which normally was protected by lead, was found to have lost its lead covering, and to be almost entirely eaten away by the vitriol. There was, therefore, an exceptional amount of sulphate of iron in the saturator bath. After remedying this, 'blue salt' ceased to be formed. When the larger plant was stopped, the smaller was set working, at first with good results, but later on, 'blue salt' was formed here too. On testing, ammonia was found to be passing away with the foul gas, and it was also noticed that there was much less 'boil' than usual in the saturator. On stopping, it was found that the delivery pipe from the still had broken off near the elbow at the bottom of the saturator, so that ammonia vapour was not getting its usual intimate admixture with vitriol. After remedying this, 'blue salt' ceased to be formed."

The number of salt works is now 53, as compared with 52 in 1904. The introduction of Mond producer gas at one of these works is favourably referred to. The total output of white salt produced from brine and salt contained in brine used for making alkali by the ammonia soda process was, in 1904 (the latest date for which returns are issued), 1,703,805 tons, as compared with 1,719,223 tons in 1903. There was again an increase in the county of Lancashire; in Durham, however, a decrease of 21,659 tons is recorded. In the counties of Chester and Stafford (grouped together in these returns), there was a further decrease of production of 11,266 tons, whilst Worcestershire showed an increase of 9,719 tons. In one salt works a new departure has been introduced in brine concentration. Several closed circular pans, mechanically worked and discharged, were erected in front of the old open pans, and fired by Mond producer gas, the waste heat from which passed on to the open pans behind them. A considerable saving of fuel is thus said to have been made in the case of a plant firing with Mond gas, and the number of these closed pans is being increased.

The recent enhanced price of white arsenic has favoured the output, which was 1528 tons in 1905, as compared with 976 tons in 1904, and 902 tons in 1903. The prospects of the associated industry of tin-smelting are encouraging. The ores have to be calcined before smelting, whatever may be the proportion of arsenic present, and when the proportion is small, the volatile products of calcination deposit so little arsenic as to be unsaleable under former conditions, whereas now, with increased value, such poorer qualities of "arsenic soot" may prove marketable.

Cement works have fallen off from the number registered in the preceding year, low prices and keen competition having necessitated much idleness of the older class of kiln. The use of rotary kilns is extending, and high chimneys (of 200 to 250 feet) are being built to serve batteries of rotary kilns; by the use of these chimneys much relief is expected as to discharge of black soot.

In Scotland there has been increased production of sulphate of ammonia and gas liquor. The works registered there during the past year comprise iron works, shale works, coke-, producer gas-, and carbonising works, and gas liquor works, the largest increase relatively, but not absolutely, being in the coke and producer gas works, due to the extended use of coke ovens, and to the extension of Mond gas plants with recovery plant attached. A further increase in these is anticipated in the near future. The total shale mined in the United Kingdom for 1904 was 2,333,062 tons; the total sulphate of ammonia recovered from the same 42,486 tons, and the yield in lb. per ton of shale mined was 40·8; the corresponding numbers for 1905 were 2,496,785 tons, 46,344 tons, and yield, 41·6 lb. per ton of shale. In 1896, the yield per ton of shale mined was only 35 lb.

The Report consists of 158 pages, of which 10 pages are devoted to Scotland.—E. S.

Alkaline-earth oxalates; Decomposition of —— by aqueous solutions of alkali sulphates. H. Cantoni. Arch. Sc. phys. nat. Gènéve, 1906, **21** [4], 308—380, 469—494. Chem. Centr., 1906, **2**, 419.

Calcium oxalate is practically unaffected by potassium sulphate solution at the ordinary temperature, and is only slightly attacked by solutions of sodium sulphate and ammonium sulphate. Barium oxalate, on the other hand, is attacked to a considerable extent by alkali sulphate solutions, whilst strontium oxalate occupies an intermediate position in this respect. It appears, therefore, that the affinity of the alkaline-earths for oxalic acid diminishes, and for sulphuric acid increases, with rise of atomic weight. (Compare Watson Smith, J. Chem. Soc., 1877 [2], 245.)—A. S.

Bismuth peroxides. IV. Oxidation of bismuth oxide by potassium ferricyanide in presence of caustic potash, and the so-called bismuth tetroxide. A. Guthier and R. Buenz. Z. anorg. Chem., 1906, **50**, 210—214.

In continuation of their previous work (this J., 1906, 263, 264, 695), the authors have repeated the experiments of Hauser and Vanino (Z. anorg. Chem., 1904, **39**, 381). They find, in opposition to those authors, that alkaline solutions of potassium ferricyanide have the same action on bismuth oxide as the other oxidising agents examined previously, and that there is no evidence of the formation of a "bismuth tetroxide" or a hydrate of the same. —A. S.

Ammonium vanadate and sodium uranate; Preparation of ——. J. Ohly. Osterr. Z. Berg.- u. Hüttenwesen, 1906, **54**, 232—234. Chem. Centr., 1906, **2**, 465—466.

The author describes the process of preparation of ammonium vanadate and sodium uranate from carnotite-containing sandstone from Utah, U.S.A. The raw material is powdered, screened, treated with hydrochloric acid (or sulphuric or nitric acid), and the mixture agitated until it acquires a reddish colour. It is then heated until the vanadium and uranium compounds are dissolved. The insoluble residue is used for the manufacture of artificial fullers' earth. A determined quantity of ammonium chloride is added to the solution, and the latter then evaporated to one-third of its volume, and allowed to stand overnight. The separated ammonium metavanadate is recrystallised from a concentrated solution of ammonium chloride, and washed with alcohol. A further crop of ammonium vanadate is obtained from the mother-liquors by evaporation and crystallisation.

The solution is treated with excess of sodium carbonate, boiled for half an hour, the precipitate filtered off, and sodium uranate precipitated from the filtrate by means of caustic soda.

The ammonium vanadate may be converted into

vanadium pentoxide by igniting it. If the pentoxide be heated to 440° C., it melts to a yellowish-brown mass, which crystallises on cooling. If the crystals be heated with gas-coke in an electric crucible furnace, a regulus of vanadium containing vanadium carbide is obtained, which can be employed in the manufacture of vanadium steel. —A. S.

Liquefaction of air; Preliminary cooling in the ——. W. P. Bradley and G. P. O. Fenwick. J. of Physical Chem., 1906, 10, 275—289. Chem. Centr., 1906, 2, 486—487.

THE decrease of temperature on the adiabatic expansion of a gas, owing to the Joule-Thomson effect is, according to Schroetter's formula: $D=\frac{P_2-P_1}{4}\left(\frac{289}{T}\right)^2$, where T is the temperature of the expansion-valve, and P_1 and P_2 are the respective pressures before and after expansion. Preliminary cooling of the air should, therefore, cause an increase in the yield of liquid air. The authors determined the effect of: (1) cooling the air before its entry into the liquefying apparatus; and (2) cooling the air inside the apparatus, before expansion, by means of previously formed liquid air. In the first case, a preliminary cooling of the air from 30° to 2° caused an increase of yield from 1·94 to 2·80 litres of liquid air, or about twice as great as that calculated by Schroetter's formula. Cooling the air, before expansion, in the interior of the liquefying apparatus had no effect on the yield of liquid air.—A. S.

FRENCH PATENTS.

Sulphuric acid; Process and apparatus for purifying [arsenical] ——. The United Alkali Co., Ltd. Fr. Pat. 363,947, March 7, 1906.

THE purification of the sulphuric acid is carried out as described in Eng. Pats. 7916 and 16,929 of 1905 (this J., 1906, 477). The arsenious chloride thus produced is mixed with just sufficient water to precipitate the selenium, and filtered; a larger quantity of water is then added to precipitate the arsenious oxide.—T. F. B.

Lithium; Extraction of —— as lithium carbonate from amblygonite and other ores of lithium. Poulenc Frères. Fr. Pat. 361,517, May 27, 1905.

POWDERED amblygonite (or other lithium-containing ore) is intimately mixed with powdered sodium bisulphate (nitre cake), and the mixture is heated in cast-iron retorts, the hydrofluoric acid and silicon fluoride disengaged, being collected. The mass is then transferred to a refractory earthen vessel, which is heated to redness. The product is lixiviated, and the solution should be neutral, and contain but small quantities of aluminium, calcium, or iron, which latter are precipitated by a small proportion of sodium carbonate. The cleared liquor is then treated with the same reagent, to precipitate lithium carbonate. Sodium sulphate is recovered from the waste liquors. The insoluble residue of the lixiviated product is stated to be rich in phosphorus, and utilisable as a manure.—E. S.

Ammonia; Process of making ——. H. C. Wolterbeck. First Addition, dated March 9, 1906, to Fr. Pat. 345,899, Aug. 6, 1904.

SEE Eng. Pat. 8358 of 1905; this J., 1906, 535.—T. F. B.

Bauxite and an alkali sulphate; Treatment of mixtures of —— for transformation into alumina and alkali sulphur compounds [Thiosulphates]. A. Clemm. Fr. Pat. 363,893, March 6, 1906.

BAUXITE, or other aluminous ore, is mixed with a large excess of an alkali sulphate and carbon, and the mixture is furnaced. The solution obtained on lixiviating the mass containing alkali sulphide and aluminate, is treated with sulphurous acid to precipitate aluminium hydroxide, and to form a thiosulphate, and the filtrate therefrom is concentrated to crystallise out the thiosulphate. The residue left on lixiviating the roasted mass is exposed to the air, with addition of milk of lime, and the solution obtained by further washing is concentrated to recover the alkali, &c., as a thiosulphate. Hydrogen sulphide may be used as the precipitant, in place of sulphurous acid, in which case the filtered solution contains sodium sulphide and hydrosulphide (Ger. Pats. 62,265 of 1891 and 93,952 of 1895 are referred to).—E. S.

Aluminium and potassium sulphates; Process for separating —— from solutions obtained by decomposing aluminium and potassium silicates or alunite by acid sulphates of the alkalis or by sulphuric acid. A. Pezzolato and M. T. de Felice. Fr. Pat. 364,265, March 15, 1906.

SEE Eng. Pat. 6122 of 1906; this J., 1906, 759.—T. F. B

Salts of the oxy-halogen acids; Electrolytic production of ——. Deutsche Solvay-Werke A.-G. First Addition, dated March 9, 1906, to Fr. Pat. 362,737, Jan. 10, 1906. XIA., page 891.

Peroxidised compounds; Manufacture of ——. Kirchhoff and Neirath. Fr. Pat. 364,249, March 14, 1906. Under Int. Conv., May 2, 1905.

AN acid solution, *e.g.*, of hydrochloric acid, is neutralised with sodium peroxide, and the saline solution of hydrogen peroxide resulting is used in obtaining metal and organic peroxides. For example, magnesium chloride solution is added, and then ammonia, to such a solution of hydrogen peroxide, with precautions against rise of temperature, to obtain a precipitate of magnesium peroxide. Zinc peroxide and calcium peroxide are similarly obtained. To obtain sodium perborate, the strong, cooled solution of hydrogen peroxide is poured into a cooled solution of borax, and a solution of sodium hydroxide is agitated with it; the sodium perborate slowly crystallises out, and is collected, and washed with iced water. Benzoyl peroxide is obtained by adding an ethereal solution of benzoic anhydride, in molecular proportion, to the crude hydrogen peroxide solution contained in a closed vessel provided with an agitator, and cooled during prolonged agitation, or until the aqueous portion of a sample withdrawn shows, on testing, only a feeble peroxide reaction. The ethereal portion of the product, when withdrawn, is distilled for recovery of the ether, and the benzoyl peroxide is crystallised out of the residue.—E. S.

Iodine; Rapid process for the extraction of —— from liquids containing iodine compounds. Soc. Française la Norgine. Fr. Pat. 361,499, May 23, 1905.

THE iodine compounds are extracted from seaweed and its ashes, and the iodine is liberated, as usual. The iodine is then extracted by systematic treatment of the liquids with "oil of vaseline," in the proportion of 60 litres of this solvent to 1000 of the liquid. From the "oil of vaseline" the iodine is recovered by heating this in a current of steam, the iodine subliming, and being condensed as usual.—A. G. L.

Oxygen; Preparation of —— by the decomposition of oxygenated salts. G. F. Jaubert. First Addition, dated May 29, 1905, to Fr. Pat. 350,377 of Dec. 7, 1904 (this J., 1906, 180).

Potassium perchlorate (preferably), or another perchlorate or a nitrate, is mixed with a small proportion of a powdered combustible, such as carbon, in presence of water, to form a composition, which is moulded into blocks or briquettes, and dried. The use of water in the manufacture of the briquettes, enabling the materials to be more intimately mingled, constitutes the salient feature of this Addition.—E. S.

Oxygen briquettes and their manufacture. G. F. Jaubert. Fr. Pat. 361,522, May 29, 1905.

This patent is substantially the same as the First Addition to Fr. Pat. 350,377 (see preceding abstract). The advantages to be derived from the addition of water in the manufacture of the briquettes having an oxygenated salt as base, are described in detail.—E. S.

Hydrogen; Process and apparatus for the manufacture of ——. E. Geisenberger. Fr. Pat. 361,492, Dec. 21, 1905.

The hydrogen is generated, alone or mixed with carbon monoxide or carbon dioxide, by the action of heat alone, or of heat and steam, on light hydrocarbons, *e.g.*, benzine, petrol, or on other materials containing hydrogen and carbon, *e.g.*, bitumen, shale, beeswax, turpentine, &c. The organic substance is heated in a retort, to which steam may be admitted, to its point of decomposition. The hydrogen is separated from the other gases in the mixture obtained, either by physical means depending on the differences in density, or by chemical means, such as absorbing the carbon dioxide by means of sodium carbonate or hydroxide solution. The whole apparatus, which is designed mainly for the filling of military balloons, is mounted on wheels so as to be easily movable.—A. G. L.

Sulphur; Manufacture of flowers of ——. J. Lagache. Fr. Pat. 364,279, March 15, 1906.

The condensation chambers for preparing flowers of sulphur are made of concrete, reinforced with metal, or with a lattice-work of metal, or of bricks resting on a metallic net, or entirely of metal. In this way the thickness of the walls can be very much reduced. The gases in the interior of the chamber are agitated by means of a powerful fan, placed either inside the chamber or outside it.—A. G. L.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 848.)

Glass; A simple method for piercing ——. P. N. Raikow. Chem.-Zeit., 1906, **30**, 867.

Holes of any desired size may be readily made in glass of any thickness up to 4 mm. by piercing the heated glass with a red-hot needle. The needle should be as pointed and as hot as possible; the glass, on the other hand, must not be warmed too much. The best procedure is to heat the needle in a Bunsen flame in such a position that its red-hot end penetrates just outside the flame; the previously-warmed glass is then pushed up against the point, and gradually brought into the flame, the needle being at the same time twisted to and fro, until it penetrates the softened glass. Before allowing the glass to cool, it should be well covered with soot to prevent cracking. Any number of holes may thus be made in a test-tube, flask, &c. For convenience in handling, the needle may be fused into a glass holder; an old thermometer forms the best holder for this purpose, as other glass usually cracks on cooling in contact with the steel needle. —A. G. L.

United States Patents.

Glass-furnace. D. J. Ghrist, Assignor to S. I. Ghrist, Hites, Pa. U.S. Pat. 828,283, Aug. 7, 1906.

The furnace described comprises a melting chamber, below and parallel to which are pairs of regenerating chambers, separated one from another, and closed at adjacent ends by a transverse wall. Each pair of regenerating chambers is connected by a flue with a port at each end of the melting chamber, fuel-discharging devices being arranged "so as to project through the end-walls at the upper ends of the flues and arranged in line with the ports, to discharge longitudinally into the melting chamber." A cave is situated on one side of the regenerating chambers, near the centre, and formed partly by one wall of the latter. The furnace is also provided with a stack, and flues arranged one above the other, on opposite sides of the transverse wall, and formed partly by it, communicate each with a separate regenerating chamber, and by vertically extending conduits with the cave. At the upper ends of the conduits are valves for controlling the supply of air from the cave to the flues, and there are also independently controlled valves in the conduits for regulating the supply of air from the cave to the regenerating chambers, and the discharge of the products of combustion from the latter to the stack. —W. C. H.

Ceramic product. M. M. Méran, Paris. U.S. Pat. 827,550, July 31, 1906.

A plastic paste is made by mixing a double silicate of lime and magnesia with a trisilicate of magnesia, or by mixing asbestos and steatite, and the paste is fired at a temperature below the vitrifying point, to yield the ceramic product.—W. C. H.

French Patent.

Glass; Apparatus for pouring molten —— direct from the furnace. P. T. Sievert. Fr. Pat. 364,151, March 8, 1906. Under Int. Conv., March 11, 1905.

See Eng. Pat. 5605 of 1906; this J., 1906, 760.—T.F.B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 848.)

English Patents.

Wood; Preservation of ——. W. Hoettger, Wesel a/Rhein, Germany. Eng. Pat. 26,993, Dec 27, 1905. Under Int. Conv., March 22, 1905.

See Fr. Pat. 352,615 of 1905; this J., 1905, 971.—T.F.B.

Portland cement; Manufacture of ——. H. Peters, Rochester, Kent. Eng. Pat. 19,180, Sept. 22, 1905.

Slurry containing about 40 per cent. of moisture is mixed with coal slack in the proportion of 4½ cwt. of coal per ton of slurry. The mixture is dried, and broken into lumps, which are charged into a vertical kiln without the addition of any other fuel except a layer of faggots and another of coke at the bottom of the kiln. In working a charge, the faggots are fired, and when the coke above them has become thoroughly ignited, the kiln door is closed, and an air blast forced in from below the fire-bars.—A. G. L.

United States Patents.

Dust; Method of and agent for laying ——. C. E. Dolbear, Longbeach, Cal., Assignor to G. N. Phelps, Boston, Mass. U.S. Pat. 828,643, Aug. 14, 1906.

"Bittern," or a liquid containing an excess of magnesium chloride, is applied to the roads to render them dustless. —B. N.

Bricks and other articles formed or constructed of clay; Process for treating ——. J. Simons, Los Angeles, Cal. U.S. Pat. 829,177, Aug. 21, 1906.

Whilst the kiln containing the bricks, &c., is at its highest temperature, the air and steam passages leading to it are shut, so that only carbonaceous gases are evolved within

the kiln. The kiln is then allowed to cool whilst its contents are exposed to the action of these carbonaceous gases.—A. G. L.

Magnesia cement. E. Büttel, Assignor to the American Hydrolite Co., Hoboken, N.J. U.S. Pat. 827,286, July 31, 1906.

The cement described consists of 36 parts by weight of an absorbent filler, such as sawdust, 85 parts of magnesium chloride solution (36·8° B.), 25 parts of infusorial earth, 75 parts of pulverised burnt magnesite, and 43½ parts of water.—W. C. H.

Cement; Process for rapid hardening of ——. H. Schneider, Cincinnati, O. U.S. Pat. 828,976, Aug. 21, 1906.

Cement is rapidly hardened by passing a current of electricity through the cement mixed with water until or after the mass has set permanently. The current must be sufficiently strong to heat the mass so much as to prevent the water from freezing.—A. G. L.

French Patents.

Marble; Process for the manufacture of artificial ——. J. Pasero. Fr. Pat. 361,494, May 20, 1905.

Portland cement is mixed with mineral colours, and moulded into objects with water containing sodium silicate and potassium silicate. After allowing the mass to dry for several days, it is placed in a mixture of 5 litres of "silicious" water and 1 litre of potassium silicate solution, which is then heated and kept boiling for 24 hours. The mass obtained is dried and polished as usual. —A. G. L.

Ceramic bricks; Burning of ——. Soc. des Céramiques de Pignans, J. Ardisson and A. Barthélémy. Fr. Pat. 363,918, Feb. 5, 1906.

The ceramic bricks, as they come from the hydraulic press, are at once surrounded by a porous mass of refractory material, previously burnt perfectly dry, the whole being carried on trucks which move along a furnace in the form of a tunnel, 50 metres in length.—A. G. L.

Portland cement from blast-furnace slag; Process for making ——. K. Zulkowsky. Fr. Pat. 364,022, March 10, 1906.

A calcareous material, preferably good limestone or quicklime, is heated in a basic hearth furnace. The molten blast-furnace slag is then run in in suitable proportion, the whole is well mixed, and then rapidly cooled. —A. G. L.

X.—METALLURGY.

(*Continued from page* 852.)

Fine iron ores and pyrites cinder; Nodulising and desulphurisation of ——. A. L. Colby. Iron and Steel Inst., July, 1906. [Advance proof.]

The author gives a description of several large plants in the United States, where there has been successfully worked, on a large scale, a process for the conversion of fine ferruginous ores and of by-products, such as pyrites cinder, into "nodules" suitable for further treatment in blast-furnaces. It is stated that since last summer over 24,000 tons of such fine materials have been successfully and economically treated. The process is essentially that described in U.S. Pat. 794,673 of 1904 (this J., 1905, 894).

The plant at Newark, New Jersey, is under the control of the National Metallurgic Co., one of the constituent companies of the Newfoundland Syndicate. At the present time there are three kilns, one for the nodulising process, one for either nodulising, or roasting with salt as a preliminary to the Henderson copper-leaching process, and one intended entirely for the latter purpose. Two more nodulising kilns will be in operation by next autumn. It is stated that the Newfoundland Syndicate control, for the next five years, 80 per cent. of the cinder made in the U.S.A. by the roasting of pyrites or copper-bearing pyrites. At the present time 250 tons of nodulised pyrites-cinder are being produced per day of 24 hours. At Aspinwall, near Pittsburgh, Pa., two large kilns, with an output of 250 tons in 24 hours, are in operation, chiefly for the working up of blast-furnace flue-dust and pyrites-cinder. At Steelton, Pa., one kiln is working, and three others are about to be built. The improvement in the composition of the nodules from the magnetic concentrates treated at Steelton is shown by the following figures, of which the first set refer to the raw material, and the second to the nodules:—Iron, 59·64, 61·25; sulphur, 1·15, 0·13; phosphorus, 0·01, 0·01; and silica, 8·50, 8·61 per cent. At Hazard, Pa., the New Jersey Zinc Co. have erected a plant for nodulising fine franklinite, a trial run on 300 tons having proved successful. From fine ore containing 17·40 per cent. of zinc, nodules containing 20·4 per cent. were obtained, with little or no loss. A description of various labour-saving devices used in connection with the process is also given. A bibliography is appended to the paper.—A. S.

Copper steels. P. Breuil. Compt. rend., 1906, **143**, 346—348.

The author has investigated the singular points in copper steels containing from 0·56 to 0·79 per cent. of carbon. From 0·5 to 20 per cent. of copper, the point Ar, lies between 575° and 600° C., 80° to 100° C. below its value for a similar carbon steel. The phenomenon of recalescence at this point becomes more marked as the percentage of copper increases. Slight separation of copper takes place when as little as 3 per cent. is present, but in such minute globules that sensibly uniform ingots can be cast, even up to 10 per cent. of copper. The metal becomes brittle only when 10 per cent. is exceeded. Mechanical tests show that copper increases the tenacity and lowers the ductility of steel, but to extents which vary greatly with the treatment of the metal.—J. T. D.

Copper steels. P. Breuil. Compt. rend., 1906, **143**, 377—380.

The effect of shock on notched bars was tried with both low- and high-carbon steels, containing various percentages of copper, up to 4 per cent. The fragility of the steel is increased, when the carbon is 0·15 to 0·18 per cent., by proportions of copper above 0·5 per cent.; but in the case of the higher carbon steels no definite effect due to the presence of the copper could be clearly detected. Torsion experiments gave similar results to those on tensile strength; in all the steels, when the copper exceeds 2 per cent., it increases considerably the elastic limit and the moment of rupture. Similar results were shown by determinations of the hardness by Brinell's method; copper steels were found to be usually superior to the corresponding nickel steels. Corrosion trials with dilute sulphuric acid showed that copper has a very powerful effect in lessening the rate of corrosion. Micrographic examination of these steels confirms the conclusions of Stead. The utilisable steels (below 4 per cent. of copper) show an extreme fineness of structure. They contain more granulo-sorbitic pearlite as the proportion of copper is increased, and the effect of this is to produce a steel with the hardness, but without the brittleness, of a steel of higher carbon content. Copper steels seem in many respects as promising industrially as those containing nickel or other elements much more costly than copper.—J. T. D.

Manganese; Compounds of —— with silicon. F. Doerinckel. Z. anorg. Chem., 1906, **50**, 117—126.

A study of the heating and cooling curves of manganese-silicon alloys, together with examination of their micro-structure, showed that two well-defined compounds are formed, Mn_2Si and MnSi. In the alloys poor in silicon there is a series of mixed crystals, ranging from pure manganese to the saturated crystals containing 17·7 atoms per cent. of silicon. In the alloys containing 37·5 per cent. by weight of silicon, or more, microscopic examination revealed the presence of parallel bands or stripes, due to a structural element of which the composition

could not be determined. Starting from manganese, melting at 1244° C., the addition of silicon causes a lowering of the melting point, and a series of mixed crystals containing from 0 to 10 per cent. of silicon separates The curve representing the beginning of crystallisation of the alloys with from 10 to 30 per cent. of silicon has a maximum at about 21·3 per cent. of silicon and a temperature of 1320° C., corresponding to the compound, Mn_2Si. Microscopic examination of alloys with from 10—20 per cent. of silicon revealed the presence of an eutectic, and from the proportions of this eutectic and of the primary crystals of the compound, Mn_2Si, the eutectic point was found to correspond to about 12 per cent. of silicon and a temperature of 1075° C. Between 30 and 50 per cent. of silicon the curve has a second maximum, at about 34 per cent. of silicon and 1280° C., corresponding to the compound, MnSi. Between the two maxima there is a second eutectic point at 1239° C., and 30 per cent. of silicon. When the percentage of silicon in the alloys rises above 37·5 per cent., the amount of the crystals of the compound, MnSi, gradually diminishes, and another structural element, indicated by parallel markings, makes its appearance, covering almost the whole surface of the section of the alloy containing 45 per cent. of silicon. With 50 per cent. and upwards of silicon, first silicon separates from the melts, and afterwards, at 1136° C., the structural element of unknown composition crystallises. (See also Vigouroux, this J., 1896, 141; 1905, 1235; and Lebeau, this J., 1903, 168, 214.)—A. S.

Zinc-gold slimes; Proposed process for treatment of —— before smelting. C. E. Meyer. J. Chem. Met. and Mining Soc., S. Africa, 1906, **6**, 361—364.

Instead of decomposing the complex cyanides with sulphuric acid, the zinc-gold slimes are placed in a vat, and dried by means of steam, any incomplete oxidation being perfected by moistening the slimes with a small quantity of nitric acid. Any excess of acid is expelled by the heating, but as little as possible should be used. This treatment will oxidise all easily decomposable cyanides. The difficultly-decomposable cyanides are then destroyed by acting on the slimes with ten times their volume of a saturated solution of ammonium carbonate, which dissolves compounds of silver, zinc, and copper. The solution obtained is filtered off, and distilled with limestone or dolomite, to recover the ammonium carbonate, the residue left in the still being worked up for silver. The residual slime left is very rich in gold, containing, in addition to the gold, only silica, ferric hydroxide, and lead carbonate. It should be fluxed with a little borax. The process is at present only in the experimental stage.

A. G. L.

Gold; Alloys of —— with bismuth and antimony. R. Vogel. Z. anorg. Chem., 1906, **50**, 145—157.

The melting-point curve of gold-bismuth alloys consists of two branches intersecting at an eutectic point (240° C., 82 per cent. of bismuth). No compound of the two metals is formed, the eutectic crystallisation of all of the alloys with from 4 to 100 per cent. of bismuth taking place at the same temperature. The alloys with from 0 to 4 per cent. of bismuth crystallise as solid solutions of bismuth in gold. With from 4 to 82 per cent. of bismuth, saturated mixed crystals, containing 4 per cent. of bismuth, separate first, until the residual melt attains the composition of the eutectic, which solidifies at 240° C. With from 82 to 100 per cent. of bismuth, the alloys consist of crystals of bismuth embedded in the eutectic, which is a mixture of saturated mixed crystals and bismuth. Microscopic examination of the alloy containing 4 per cent. of bismuth showed that this did not consist entirely of mixed crystals, as would have been expected; this is due to the incomplete diffusion of the bismuth into the gold. After heating at 400°, 500°, 700°, and 800° C. respectively, the structure of the alloy was found to be quite different, consisting of crystals of gold embedded in the eutectic. It appears therefore that at high temperatures the diffusion of bismuth into gold is very small, but is much greater at temperatures below 400° C.

In the case of gold-antimony alloys, the melting point of gold is lowered considerably by addition of antimony; the alloy containing 24 per cent. of antimony still remains liquid above 360° C. The melting-point curve of the alloys consists of three branches. Starting from the melting point of gold, it falls rapidly to the eutectic point (360° C., 24 per cent. of antimony), then rises to a point at 460° C., corresponding to the compound, $AuSb_2$ (55 per cent. of antimony), and then again rises to the melting point of bismuth. From the melts containing less than 24 per cent. of antimony, crystals of gold separate out first, and the residual melt solidifies at the eutectic point; the eutectic consists of a mixture of gold and the compound $AuSb_2$. With from 24 and 55 per cent. of antimony, the alloys consist of crystals of the compound, $AuSb_2$, embedded in the eutectic; whilst with from 55 to 100 per cent. of antimony, the alloys consist of crystals of antimony surrounded by the eutectic. The compound, $AuSb_2$, crystallises in cubes; it is harder than antimony and gold, very brittle, and more resistant to acids than antimony is.—A. S.

Silver; Alloys of — with thallium, bismuth, and antimony. G. I. Petrenko. Z. anorg. Chem., 1906, **50**, 133—144.

The melting-point curve of silver-thallium alloys consists of two branches starting from the melting points of silver and thallium respectively, and intersecting at an eutectic point (287° C., 2·5 per cent. of silver). The melts containing 0—10 per cent. of thallium solidify as mixed crystals of thallium and silver. As the percentage of thallium rises from 10 per cent. upwards, the amount of mixed crystals decreases, whilst the eutectic is formed in gradually increasing quantities. The alloy with 95 per cent. of thallium consists of star-shaped mixed crystals embedded in the eutectic, but at 97·5 per cent. of thallium, the alloy consists entirely of eutectic. With more than 97·5 per cent. of thallium the alloys consist of primary crystals of α-thallium embedded in the eutectic; crystals of β-thallium separate from the melt, but are transformed into α-thallium at 226° C.

The melting-point curve of silver-bismuth alloys has a somewhat unusual form; it consists of two branches intersecting at an eutectic point (262° C., 2·5 per cent. of silver), but the branch beginning at the melting point of silver is distinctly concave at the part corresponding to about 40 per cent. of bismuth. Microscopic examination showed that the alloys containing 17 to 95 per cent. of bismuth consist of two structural elements, *viz.*, white mixed crystals rich in silver, embedded in the grey, microcrystalline eutectic. The alloy with 2·5 per cent. of silver consists entirely of the eutectic, whilst that with 1 per cent. of silver consists of crystals of bismuth embedded in the eutectic. The melts containing more than 95 per cent. of silver solidify, on cooling, as a solid solution of bismuth in silver, but it was not found possible to determine exactly the composition of the saturated mixed crystals.

The melting-point curve of antimony-silver alloys falls rapidly from the melting point of silver to a point at 560° C., corresponding to the compound, Ag_3Sb, and then less rapidly to the eutectic point (485° C., 45 per cent of antimony), from which it rises to the melting point of antimony. With from 0 to 15 per cent. of antimony the alloys consist of mixed crystals containing up to 15 to 16 per cent. of antimony. From 15 to 25 per cent. of antimony, two structural elements are observed in the alloys: saturated mixed crystals and the compound Ag_3Sb (27·07 per cent. of antimony, 559° C.). With from 27·07 to 45 per cent. of antimony, the compound, Ag_3Sb, separates first, and then at 485° C. the eutectic (45 per cent. of antimony) crystallises. Between 45 and 100 per cent. of antimony the alloys contain two constituents, metallic antimony and the eutectic. (See also Laurie, this J., 1894, 1204.)—A. S.

Copper mining in Chile. For. Off. Ann. Ser., No. 3698. [T.R.]

There was an increase in the shipments of fine copper from Chile to the amount of 9,601 met. quintals, the total amount being 296,313 met. quintals. 238,934 quintals of bar copper were exported; of this amount 179,560 quintals were shipped to the United Kingdom, and 47,104 quintals to France. The total export of this article showed an increase of 17,070 quintals over 1904.

In copper regulus the total amount exported amounted to 15,683 met. quintals of fine copper, as compared with 6,654 met. quintals in 1904. There was an increase in export to the United Kingdom. The total amount of ores exported equalled 41,696 quintals of fine copper, or 1,560 met. quintals less than during the year 1904. Of the total export of this article, the United Kingdom took 38,454 quintals.

Copper alloys; Microscopic structure of ——. J. Jacobsen. Bull. Soc. Chim. Belg., 1906, **20**, 214–230.

The author has examined and gives plates of the microscopic structure of pure copper and of a number of bronzes and brasses. Mechanical tests were also made of each sample examined. The work is still in a preliminary stage, but already permits the following conclusions to be drawn:—1. Alloys giving good results in both tensional and shock tests show a homogeneous and regular structure (by regular is meant that the crystal axes are all in the same direction). 2. Alloys giving poor results both in tensional and shock tests show a structure neither homogeneous nor regular. 3. Alloys giving poor tensional results, but having a high resistance to shock, show a homogeneous but irregular structure.—J. T. D.

Barium; Preparation of —— from its suboxide. Guntz. Compt. rend., 1906, **139**, 339—340.

When metallic magnesium and barium oxide are heated to 1100° C., the reaction $2BaO+2Mg=Ba_2O+MgO+Mg$ occurs, half of the magnesium volatilising. If a larger proportion of magnesium be used, an alloy of barium and magnesium may be condensed in the apparatus; and if for the magnesium be substituted a non-volatile metal such as aluminium, the dissociation of the barium suboxide gives rise to pure barium. Barium suboxide decomposes water in the cold. At a red heat it also absorbs nitrogen, giving a nitride; and hydrogen, yielding a hydride.

Strontium behaves in all these respects similarly to barium.—J. T. D.

Antimony-thallium alloys. R. S. Williams. Z. anorg. Chem., 1906, **50**, 127–132.

Molten antimony and thallium are miscible in all proportions. From the melts containing from 22 to 100 atoms per cent. of antimony there separate, on cooling, either crystals of antimony, or saturated mixed crystals of antimony in α-thallium, containing about 22 atoms per cent. of antimony, until the residual melt attains the composition of the eutectic (29·8 atoms per cent. of antimony), which solidifies at 195° C. From the melts containing 0 to 22 atoms per cent. of antimony, on cooling, crystals of β-thallium separate; at 225° C. these are transformed into α-thallium, whilst at 195° C. the remainder of the melt solidifies as the eutectic. In all of the solid alloys, at 187° C., or 8° below the eutectic point, crystals of the compound, $SbTl_3$, are formed according to the following equations:—(1) Alloys with from 22 to 100 atoms per cent. of antimony:—

1 mol. $SbTl_3 \rightleftarrows$ 0·961 mol. of mixed crystals (22 atoms per cent. of antimony) + 0·154 mol. Sb.

(2) Alloys with from 0 to 22 atoms per cent. of antimony:—

1 mol. $SbTl_3 \rightleftarrows x$ mols. of mixed crystals + y mols. Tl.

Micrographic examination of the alloys showed that the alloys containing from 29·8 to 100 atoms per cent. of antimony consist of three structural elements, *viz.*, primary crystals of antimony; a homogeneous straw-yellow compound, $SbTl_3$, of ill-defined crystalline structure; and a mixture of this compound with very small, somewhat bent rods of antimony, derived from the eutectic. The alloy, with 29·8 atoms per cent. of antimony, consists of the compound, $SbTl_3$, and the small rods of antimony. With from 29·8 to 25 atoms per cent. of antimony, the quantity of the compound, $SbTl_3$, increases, and that of the rods of antimony decreases. As the amount of antimony is reduced below 25 atoms per cent., the amount of the small rods of antimony decreases rapidly (disappearing altogether at about 22 atoms per cent. of antimony), that of the compound, $SbTl_3$, decreases slowly, and that of the mixed crystals of antimony in α-thallium increases. —A. S.

Thorium; Preparation of [metallic] ——. H. Moissan and O. Hönigschmid. Monatsh. Chem., 1906, **27**, 685—696.

Thorium has never hitherto been obtained free from oxide, the purest specimen having been that prepared by Nilson, which contained 19·85 per cent. of thorium dioxide. The authors endeavoured to obtain a purer preparation by first heating thorium carbide in a stream of chlorine, and re-subliming the product in a current of hydrogen, to obtain anhydrous, oxygen-free thorium chloride; the chloride was then placed in an iron crucible, along with alternate layers of sodium and sodium chloride; and the crucible was closed tightly and heated. The product so obtained, however, contained over 15 per cent. of thorium dioxide, the oxygen having evidently been derived from moisture absorbed by the hygroscopic thorium chloride during its transference to the crucible. To meet this difficulty, the experiments were repeated in glass tubes, in such a way that the sublimation of the chloride, and the reduction with sodium were conducted *in vacuo*. The glass of the tubes was found to be attacked, however, with formation of some silicon chloride, so that some thorium oxide was produced; nevertheless, the metal obtained was found to contain as little as 3·08 per cent. of oxide. Attempts were made to improve upon this result by electrolysing anhydrous thorium-potassium chloride in an atmosphere of nitrogen. Experiments showed that only porcelain vessels were available for the purpose, but the porcelain was always found to be more or less attacked, with consequent formation of oxide. The best product contained 5·1 per cent. of oxide. Some of the metal so obtained was packed in a cavity in a tightly-rammed block of thoria, contained in a carbon crucible, and the whole was heated in an electric flaming-arc furnace. On opening up the mass at the conclusion of the experiment, the metal was found to have volatilised partly; but a few small metallic beads were encountered, and these proved to consist of perfectly fused thorium, free from oxide.—H. B.

Mineral industry of Austria. Mining World, Sept. 1, 1906. [T.R.]

In 1905 there were employed 136,316 men in the mining industry; 8,289 men worked at the smelters, and 7,210 men and women were employed at the salt plants.

The output in the last two years compares as below, in metric tons, unless otherwise specified:—

	1904.	1905.
Antimony ore	103	1,673
Antimony	36	90
Coal (bituminous)	11,868,245	12,585,263
Coal (lignite)	21,987,651	22,692,076
Copper ore	10,701	10,677
Copper	889	870
Gold ore	12,653	35,937
Gold (kilos.)	71	204
Graphite	28,020	34,416
Iron ore	1,719,219	1,913,782
Iron, pig	820,055	947,035
Iron, cast	168,309	172,579
Lead ore	22,514	23,339
Lead	12,645	12,968
Litharge	783	865
Manganese ore	10,189	13,788
Mercury ore	88,279	86,856
Mercury	536	520
Salt	369,877	343,375
Silver ore	21,048	21,047
Silver (kilos.)	39,032	38,453
Tin ore	77	52
Tin	38	53
Zinc ore	29,226	29,983
Zinc	9,159	9,326

The output of 1905 was valued at £15,276,000, of which £11,128,000 represented minerals, and £4,128,000 metallurgical products.

Mineral industry of Sweden. Mining World, Sept. 1, 1906. [T.R.]

During the past year there has been marked activity in mining, notably in iron mining. There were employed in

1905 a total of 14,574 men in the mines and quarries, and 16,648 at metallurgical works making in all 31,222, who have produced approximately £665,300 worth of minerals and metallurgical products. There were 591 accidents in the mines and quarries, of which 24 were fatal, and 518 accidents in the metallurgical industry, of which 6 were fatal. The ratio of accidents to the number of employés is comparatively small, since there were in operation in 1905, 404 mines and quarries, and 186 metallurgical plants.

The production in the last two years compares as follows, in metric tons, unless otherwise specified :—

	1904.	1905.
Coal	320,984	322,384
Copper ore	36,834	39,255
Copper	533	1,385
Copper sulphate	1,248	1,029
Felspar	18,021	19,224
Fireclay	166,888	119,947
Gold (kilos.)	61	55
Iron ore	4,083,945	4,304,833
Pig iron	528,525	530,437
Wrought iron, crude	189,246	182,640
Bessemer ingots	78,577	78,204
Basic ingots	252,832	288,075
Crucible ingots	1,162	1,319
Bars, &c., of iron and steel	252,888	284,380
Wire rods	31,863	36,009
Tubes, steel	23,594	21,809
Sheets, iron and steel	16,331	14,700
Lead	589	576
Manganese ore	2,297	1,992
Pyrites	15,957	20,762
Silver (kilos.)	651	606
Silver-lead ore	8,187	8,397
Zinc	333	305
Zinc ore	57,634	56,885

In 1905 the iron industry had 24 magnetic separating plants and 9 concentrators, which produced 221,744 tons of clean iron ore. The 139 blast furnaces worked an average of 270 days each.

Ammonium vanadate and sodium uranate ; Preparation of —. J. Ohly. VII., page 883.

English Patents.

Iron and steel ; Hardening and toughening of —. J. Churchward, New York. Eng. Pat. 15,423, July 27, 1905.

Small percentages of chromium, nickel, and manganese are mixed with the metal, which is cast into ingots, in contact with a surface containing manganese ; the ingots, after being reduced in thickness by pressure, are plunged whilst hot into a liquid bath containing fatty substance and phenol.—J. H. C.

Iron ore ; Process for reducing —. P. A. Newton, London. From Westman Process Co., Jersey City, U.S.A. Eng. Pat. 2988, Feb. 7, 1906.

See U.S. Pat. 812,247 of 1906 ; this J., 1906, 269.—T. F. B.

Magnetic materials ; Treatment of —. R. A. Hadfield, Sheffield. Eng. Pat. 6426, March 16, 1906.

The permeability of an alloy, low in carbon and manganese, in which a magnetic body (iron) and silicon, or its equivalent, form the principal constituents, is increased, and its hysteresis action reduced by heating within the range of temperature of "gamma iron" or above the critical point of the alloy (about 1050° C.), and then cooling at the rate of about 10° per hour.—J. H. C.

Sulphide and other ores [Galena] ; Treatment of —. G. E. Kingsley, Toronto, Canada. Eng. Pat. 16,374, Aug. 11, 1905.

The ores are treated in a closed solution tank, provided with a filter bottom, with a solution of nitric acid of a strength not exceeding 7½ per cent., and preferably heated (as described in Eng. Pat. 23,909 of 1904 ; this J., 1905, 681), whereby the lead is entirely dissolved, the formation of lead sulphate being entirely prevented.—J. H. C.

Ores ; Treatment of sulphide and other —. A. J. Boult, London. From H. F. Brown, Chicago. Eng. Pat. 25,371, Dec. 6, 1905.

See U.S. Pats. 817,414 and 817,415 of 1906 ; this J., 1906, 481.—T. F. B.

Silver ; Selective solvents for —. F. J. Hobson, Guanajuato, Mexico. Eng. Pat. 17,310, Aug. 26, 1905.

See U.S. Pat. 827,368 of 1906 ; this J., 1906, 851.—T.F.B.

Alloys. C. H. Birmingham, Baltimore, Md., U.S.A. Eng. Pat. 13,186, June 7, 1906.

An alloy designed to replace platinum in electrical appliances, having a high melting point and high induction and resistance, is composed as follows : Silver, 16½ oz. troy ; nickel, 4½ lb. ; bismuth, ½ oz. ; gold, 53 dwt.—A. G. L.

United States Patents.

Copper and other metals ; Process of treating [deoxidising] —. J. A. Yunck, South Orange, N.J. U.S. Pat. 825,100, July 3, 1906.

Instead of using an alkali metal for the deoxidation of copper, the patentee uses a mixture of an alkali carbonate with free carbon, which, it is claimed, is reduced at the temperature of the molten metal, with evolution of the vapour of the alkali metal. In order to prevent the too rapid evolution of the alkali metal vapour, a small quantity of a "retarder" is added, *viz.*, calcium carbonate when sodium carbonate is employed, or cream of tartar when potassium carbonate is used. In carrying out the process, 30 parts of powdered carbon and 5 parts of granular carbon are mixed with 5 parts of calcium carbonate and 60 parts of sodium carbonate, sufficient water is added to dissolve the sodium carbonate, the mixture is evaporated to dryness, and the residue is crushed. This product is added to the copper to be deoxidised in the proportion of 1 part to 19 parts of copper. Ten per cent. of the required quantity of the deoxidising mixture is added to the copper, the mixture is fused, and then the remaining 90 per cent. of the mixture is added, and the whole is well stirred before pouring the copper. —A. S.

Vanadium ores ; Process of treating —. J. H. Haynes and W. D. Engle, Denver, Colo. U.S. Pat. 828,350, Aug. 14, 1906.

The ore is crushed, boiled with a solution of alkali carbonate until the vanadium is dissolved, the solution drawn off, and the vanadium precipitated as calcium vanadate by the addition of slaked lime.—A. S.

Metal or metallic compound ; Deposition of — *upon metals or metallic articles.* S. O. Cowper-Coles, London. U.S. Pat. 829,386, Aug. 28, 1906.

See Eng. Pat. 13,579 of 1904 ; this J., 1905, 804.—T.F.B.

Crucible furnace. M. Harvey, Cannock. U.S. Pat. 829,471, Aug. 28, 1906.

See Eng. Pat. 23,909 of 1903 ; this J., 1904, 753.—T.F.B.

French Patents.

Steel alloys for armour plates. Schneider and Co. Fr. Pat. 351,411, April 25, 1905.

The new alloys have the following composition :—

1. Steel-nickel-molybdenum contains carbon not exceeding 0·25 per cent., nickel about 3½ per cent., molybdenum at least 0·5 per cent.

2. Steel-nickel-chrome-molybdenum contains carbon not exceeding 0·25 per cent., nickel about 3 per cent., chromium about 0·5 per cent., molybdenum at least 0·5 per cent.

3. Steel-nickel-tungsten contains carbon at most 0·25 per cent., nickel about 3·5 per cent., tungsten at least 1 per cent.

4. Steel-nickel-chrome-tungsten contains carbon at most 0·25 per cent., nickel about 3 per cent., chromium about 0·5 per cent., tungsten at least 1 per cent.—J.H.C.

Iron, steel, &c. ; Process for preventing the rusting of ——. F. Montefredini. Fr. Pat. 364,082, Jan. 13, 1906.

The metal is heated to 538°—760° C., and treated under pressure with suitable "protective gases or vapours" (*e.g.*, calcium vapour, or the vapour from litharge, either alone or mixed with turpentine). After cooling, the metal may be coated with vaseline. In carrying out the invention, the metal is cleaned, and heated in a closed retort into which a suitable quantity of quicklime and of litharge, preferably mixed with turpentine, is introduced.—A. S.

Iron and steel ; Manufacture of ——. Hasper Iron and Steel Works. Fr. Pat 365,282, Feb. 14, 1906.

The addition of ferro-manganese in the converter is rendered unnecessary, and the production of good steel facilitated, by blowing finely-divided graphite or other carbon powder into the molten iron during the whole period of dephosphorisation.—J. H. C.

Iron ; Process for the partial or complete transformation of —— into steel. A. Darracq and Co. Fr. Pat. 364,112, Feb. 16, 1906. Under Int Conv , Dec. 24, 1905.

The process for the partial or complete transformation of iron into steel consists in heating the metal, whilst it is coated with a mixture of powdered horn, potassium ferrocyanide, potassium bichromate, and ammonium chloride in variable proportions, and then cooling it by immersion in cold water. A. S.

Bronze ; Unoxidisable —— of high resistance. C. J. M. Lagatinerie. Fr. Pat. 361,460, May 11, 1905.

The principal characters of this new bronze are that it offers great resistance to oxidation, has great tensile strength, is very hard, ductile, and malleable It consists of copper 57·4 per cent., tin 0·4 per cent., zinc 40·5 per cent., aluminium 0·1 per cent., manganese 0·1 per cent., and mild steel 1·5 per cent.—J. H. C.

Gilding objects of metal, other than copper, by simple immersion. A. Weil. Fr. Pat. 363,092, Feb. 8, 1906.

A band of zinc is placed around the object to be gilded ; it is then immersed in the bath of potassium cyanide and gold chloride so as to more or less completely cover the zinc.—J. H. C.

Minerals ; Concentration of ——. H. L. Sulman, H. F. K. Picard, and J. Ballot. Fr. Pat. 363,418, Feb 19, 1906.

Finely-divided mineral while suspended in water, preferably acidulated, is submitted to the intermittent action of gas under pressure, whereby on the pressure being relaxed, certain particles are floated to the surface by the escaping gas.—J. H. C.

Minerals ; Separation of ——. H. L. Sulman, H. F. K. Picard, and J. Ballot. Fr. Pat. 363,419, Feb. 19, 1906.

Certain finely-divided minerals may be separated from each other by being brought into alternate contact with air and the surface of a liquid. The minerals are placed in a cylinder which rotates on a horizontal axis. The cylinder is furnished with an internal helix whereby the bulk of the mineral is gradually pushed forward. A shallow stream of water is made to flow in an opposite direction, and certain particles which float to the surface of this current are carried off to a separate receiver. —J. H. C.

Minerals ; Process for reducing ——. C. P. Townsend. Fr. Pat. 364,379, March 17, 1906.

See U.S. Pat. 815,881 of 1906 ; this J., 1906, 381.—T.F.B.

Furnace ; Rotating ——, *for the treatment of ores and of combustible substances.* A. Ducco. Fr. Pat. 364,366, March 10, 1906. Under Int. Conv., April 18, 1905.

The invention relates to a rotating furnace, intended more especially for the treatment of pyritic ores. The furnace consists of a long cylindrical chamber, horizontal or slightly inclined, and supported, so as to rotate, on friction wheels. The chamber is provided at either end with an opening—one for the introduction of the material under treatment, and the escape of the products of combustion, and the other for the discharge of the roasted material, and the introduction of air. The inner surface of the cylinder has helical grooves or channels cut in it, so that as the cylinder rotates, the charge is moved gradually from one end to the other. The charging device is fixed to the cylinder and rotates with it ; in successive positions of the device, material is taken up from a receptacle, and is dropped (1) through a flap-door, which closes after it; (2) through a second flap-door which is closed whilst the first is open, and *vice versâ*; and (3) into the cylinder.—A. S.

Metals, metalloids, and alloys ; Process for the manufacture of ——. K. A. Kuhne. Fr. Pat. 364,329, March 17, 1906. Under Int. Conv., Oct. 14, 1905.

The invention relates to a method of obtaining metals or metalloids, or alloys of the same with aluminium, which cannot be prepared by Goldschmidt's "thermite" process. The oxide or hydroxide of the metal or metalloid is mixed with aluminium and potassium chlorate or an analogous substance, all in a finely divided condition, and the mixture is ignited as in the "thermite" process. For example, three parts of an oxygenated compound of boron are mixed with nine parts of aluminium and five parts of potassium chlorate, and the mixture is ignited by means of a red hot iron rod. The mixture burns, and fuses. After solidifying, the residue consists of two layers which can be easily separated—the upper one of slag, and the lower one of aluminium containing crystals of boron. —A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 856.)

(*A.*)—ELECTRO-CHEMISTRY.

Potassium chlorate ; Simple continuous electrolytic preparation of ——. A. Wallach. Z. Elektrochem., 1906, 12, 667—668.

The electrolyte consisted of a 25 per cent. potassium chloride solution containing 0·2 grm. of potassium bichromate per 100 c.c. From time to time small quantities of concentrated hydrochloric acid were added, in all some 0·8 c.c. per 100 c.c. of electrolyte. The electrolysis was effected between platinum gauze electrodes with a current density of 0·15 amps. per sq. cm., the temperature attaining 70° C. The experiments lasted from 24 to 90 hours, the electrolyte being stirred, and a concentrated solution of potassium chloride being continuously added in proportion sufficient to make up for the converted salt and evaporation. In some of the experiments, the crystals of potassium chlorate, which settled at the bottom of the cell, were removed at intervals. The current yield varied between 85 and 92 per cent. of the theoretical, and the chlorate obtained was practically pure, and scarcely coloured by the chromate.—R. S. H.

FRENCH PATENTS.

Salts of the oxy-halogen acids; Electrolytic production of ——. Deutsche Solvay-Werke A.G. First Addition dated March 9, 1906, to Fr. Pat. 362,737, Jan. 10, 1906 (this J., 1906, 766).

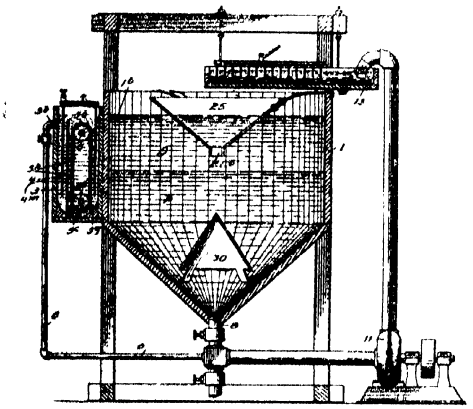
SOLUBLE salts of titanium or iron are added to the solution of alkali or alkaline-earth halogen compound, with a view to suppressing the cathodic reduction during the electrolysis.—R. S. H.

THE positive electrode is formed of a number of discs, *l*, partially immersed in the electrolyte, and connected electrically in parallel. The negative electrodes (*m,n,*) consist of a number of plates which are completely immersed in the electrolyte, and are so arranged as not to take part in the rotatory movement which is applied to the apparatus. The cell proper, is contained in a vessel (*h,g,*) of insulating material (glass, &c.), which is enclosed in a steel chamber (*c,d,*) and is placed in connection with a store of liquid chlorine in a subsidiary vessel (*a*), by means of a valve.—R. S. H.

Oils and similar organic substances; [Electrical] hydrolysis of —— . E. T. B. Simpson. Fr. Pat. 364,587, March 26, 1906. XII., page 894.

(*B.*)—ELECTRO-METALLURGY.

Silver and gold; Electro-chemical processes for extraction of ——. M. Vaygouny. Electrochem. and Met. Ind., 1906, **4**, 314—316.



Two processes are described, in the first of which a chlorination method of extraction is adopted. The leaching solution contains a small percentage of ferric chloride, 15—20 per cent. of sodium chloride, and some free acid. The extraction of silver from sulphide and other ores was over 95 per cent., that of gold 60—88 per cent., but the extraction of the latter metal decreases if the ferrous salt be allowed to accumulate. The regeneration of the ferric salts can be accomplished by electrolysis without a diaphragm, and the silver and gold can be recovered electrolytically.

The second method relies on the use of persulphates, which not only dissolve gold, but oxidise sulphide ores, converting the silver present into sulphate, which is soluble in the sodium chloride used along with the persulphate. The solution recommended contains 2 per cent. of potas-

sium persulphate, 5 per cent. of sulphuric acid, and 20 per cent. of sodium chloride. It is stated that the difficulty of regenerating the persulphate can be satisfactorily overcome by crystallising out the potassium sulphate from the spent solvent, and separately electrolysing this to obtain the persulphate.—R. S. H.

United States Patents.

Precious metals; Apparatus for recovering ——. E. J. Garvin, Assignor to the Garvin Cyanide Extraction Co., Portland, Oregon. U.S. Pat. 822,940, June 12, 1906.

The patent relates to improvements in the apparatus described in U.S. Pat. 809,939 of 1906 (this J., 1906, 187), the chief novel features being improved means for feeding the material to the main tank, and for spreading it on the bottom thereof, and also in the arrangement of the precipitating tank. In the figure, 13 is the amalgamating tank, which discharges into the funnel, 25, suspended within the main tank, 1. The material falls from the funnel through the opening, 25*b*, and is spread over the bottom of the main tank by the distributor, 30. In the main tank the material separates into two layers—of pulp, P, and solvent, S, respectively. The solvent passes through the pipe, 1*b*, situated above the discharge opening of the funnel, into the rectangular precipitating tank, 3. In the precipitating tank are mounted two shafts, 5, 5*a*, carrying sprocket-wheels, 5*b*, 5*c*, round which pass endless chains, 5*g*, formed of suitably spaced copper strips, 5*h*. The endless chains act as cathodes, and dip into mercury, contained in the concave bottom of the tank. The tank also contains anode plates, 4, and a supplementary cathode plate, 4*m*, which form a tortuous passage for the liquid. From the precipitating tank, after separation of dissolved precious metals by electrolysis and amalgamation, the solution passes away through the outlet, 3*b*, and the pipe, 6, mixes with pulp issuing from the main tank through the opening, 8, and is returned by the pump, 11, to the amalgamating tank, 13.—A. S.

French Patents.

Copper; Metallurgical and electro-metallurgical process for obtaining pure ——. L. Jumau. Fr. Pat. 364,430, March 20, 1906.

A solution containing copper, obtained by any ordinary process, is submitted to the following treatment:—A precipitate of cuprous sulphite is first formed by the action of sulphur dioxide or a sulphite; or, if desired, a double sulphite, with ammonia, is produced. The precipitated cuprous sulphite is either directly formed into bars or rods, on a core formed of a suitable conductor, such as metallic copper, and is made the anode in an ordinary electrolytic copper-refining vat; or is decomposed with some acid incapable of forming cuprous salts, *e.g.*, sulphuric acid. In this latter method, for example, sulphuric acid precipitates metallic copper ($Cu_2SO_3 + H_2SO_4 = Cu + CuSO_4 + SO_2 + H_2O$), which, after either compression or fusion, may be employed in the ordinary electrolytic refining process.—R. S. H.

Copper from old bronzes; Regeneration of electrolyte serving for the extraction of ——. A. J. M. Thirot and L. A. Mage *dit* Nonguier. Fr. Pat. 364,588, March 26, 1906.

In the electrolytic recovery of copper from old bronze, the electrolyte gradually becomes poorer and poorer in copper sulphate, owing to the solution of foreign metals. To remedy this, the patentee proposes to add to the electrolyte sulphuric acid and copper oxide from time to time, whereby fresh quantities are formed. The copper oxide is obtained by heating metallic copper, or the bronze itself, in a current of air.—R. S. H.

Furnaces; Electric ——. A. G. Betts. Fr. Pat. 364,476, Feb. 8, 1906.

See U.S. Pat. 816,554 of 1906; this J., 1906, 433.—T. F. B.

Induction furnace; New form of electric ——. Soc. des Procédés Gin pour la Métallurgie Electrique. Fr. Pat. 363,937, March 7, 1906

The crucible or containing vessel consists of a series of uncovered channels, the bottoms of which are inclined towards closed conduits, which form the lateral connections between the several channels. In this way the deepest portion of each channel is put into communication with the top of the succeeding channel. The whole series forms a closed electrical circuit, and the heating causes a general and continuous circulation of the molten charge.—R. S. H.

Depolarisation of electrodes; Arrangements employed in electrolysis for the ——. A. Levy. Fr. Pat. 363,931, March 1, 1906.

The depositing vat is supplied with a system of pipes, and a pump, enabling the electrolyte and the bubbles of gas to be withdrawn from near the bottom of the vessel. The electrolyte is forced back again in a fine shower, which falls upon the articles undergoing plating.—R. S. H.

Aluminium; [Electrolytic] Process for reducing ——. A. G. Betts. Fr. Pat. 364,521, March 23, 1906. Under Int. Conv., April 1, 1905.

See U.S. Pat 795,886 of 1905; this J., 1905, 932.—T. F. B.

Celluloid, horn, &c.; Decoration of —— with metallic deposits of gold, silver, &c. L. Schwob and G. H. Dilette. Fr. Pat. 364,559, March 24, 1906. XIX., page 906.

Metallic tin; Production of —— in a pure and adherent form by electrolysis. A. J. M. Thirot and L. A. Mage *dit* Nonguier. Fr. Pat. 364,589, March 26, 1906.

Hydrated tin oxides, obtained in the electrolytic recovery of copper from bronze, or otherwise, are dissolved in a 10 to 12 per cent. solution of sodium hydroxide; the solution is then purified by addition of the quantity of sodium sulphide requisite to precipitate the foreign metals in solution. The solution of sodium stannate, containing 45 to 50 grms. of tin per litre, is submitted to electrolysis at 80° C., employing iron anodes and thin sheet-tin cathodes. The current density should be 300—400 ampères per sq. m. at 2·4 volts. The electrolyte, after the content of tin has been reduced to about 10 grms. per litre, is employed for extracting a fresh quantity of hydrated tin oxide.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 857.)

Linseed oil; Examination of ——. H. Thoms and G. Fendler. Chem.-Zeit., 1906, **30**, 832.

Various conclusions arrived at by Niegemann (Chem.-Zeit., 1904, 724) with regard to the unsaponifiable matter have been critically examined by the authors. They find

that linseed oil, left in contact with its deposited sediment, does not show a considerable increase in the proportion of its unsaponifiable matter with a decrease in the iodine value of the unsaponifiable matter. For example, a sample of fresh oil, yielding 1·08 per cent. of unsaponifiable matter, with iodine value 95·24, was left in contact, with constant stirring, with the deposited sediment from another oil, and filtered after six weeks, and it then gave 1·08 per cent. of unsaponifiable matter, with iodine value 95·56. Again, the authors deny that the amount of unsaponifiable matter is increased by auto-oxidation of a linseed oil. Thus, the above-named sample of oil from Archangel seed (with 1·08 per cent. of unsaponifiable matter), after being exposed to air and light for three months in a shallow dish, until it had dried to a varnish, gave 1·12 per cent. of unsaponifiable matter, with iodine value 60·13. The proportion of unsaponifiable matter is not materially decreased by the "breaking" of the oil, for the same oil, heated over a naked flame till "breaking" occurred, and then filtered, gave 1·055 per cent. of unsaponifiable matter, with iodine value 86·78. Normally the amount of unsaponifiable matter does not exceed 2 per cent., and although Niegemann (this J., 1904, 207) has found higher values, the authors attribute them to errors in his method of determination, or to his linseed oils not being pure. There is no great variation in the iodine values of the unsaponifiable matter from different linseed oils, and the determination of that value is a good test for the detection of small quantities of mineral oil. Under normal conditions the iodine value of the unsaponifiable matter does not show any material decrease, even when the linseed oil has been exposed in small quantities to the air for a month in the dark, although it is appreciably lowered when the oil has also been subjected to the action of light. Yet, even then, the decrease does not destroy the value of this test for mineral oil, and it is only when the linseed oil has been allowed to dry to a varnish that there is any marked reduction in the iodine value. The consistency of the unsaponifiable matter and its solubility in hot 90 per cent. alcohol have also some value for the detection of mineral oil. The proportion of unsaponifiable matter in extracted linseed oil is not less than in the case of expressed oil, although the contrary was asserted by Niegemann. Thus, a sample of freshly expressed oil contained 1·09 per cent. of unsaponifiable matter, whilst oil extracted with ether from the same seeds yielded 1·24 per cent.—C. A. M.

Castor oil and ground nut [arachis] oil from Southern Rhodesia. Bull. Imp. Inst., 1906, **4**, 97—98.

THE castor oil was of good quality, but was slightly turbid. After filtration, its value would be £26—£28 per ton. It gave the following analytical figures:—Sp. gr. at 15·5° C., 0·959; acid value, 1·2; saponification value, 179·6; iodine value, 87. One part of the oil dissolved in five parts of 90 per cent. alcohol to a clear solution.

The specimen of arachis (ground nut) oil was found to be of a quality probably superior to that of the highest grade oil met with in this country; it would be worth about £40 per ton. The following analytical figures were obtained for the oil: Sp. gr. at 15·5° C., 0·916; acid value, 2·0; saponification value, 188·1; iodine value, 93.—A S.

Java olives; Oil of ——. K. Wedemeyer. Z. Untersuch. Nahr.- u. Genussm., 1906, **12**, 210—212.

THE Java olive is the seed of a plant belonging to the *Sterculiaceæ*, and is not at all like the fruit of the S. European olive. The specimen of the fruit examined by the author was exported from Java as an experimental shipment. The black parchment-like hulls contained no oil, but the shells yielded 9·8 per cent. of a white butter-like fat, and the cotyledons 46·6 per cent. of a pale yellow fluid oil. The whole fruit (hulls, shells, and cotyledons) gave 30·3 per cent. of a similar fluid oil. The Java olives before extraction of the oil contained 29·3 per cent. of proteids. The oil is used by the natives of Java for food, and as a lamp oil. That expressed by the author resembled olive oil in appearance, and had a pleasant taste, but slightly rancid odour. It was miscible in all proportions with ether and petroleum spirit, but was insoluble in 95 per cent. alcohol. It remained fluid at the ordinary temperature, and did not give any solid deposit. It gave the following results:—Free fatty acids, 2·6 per cent.; sp. gr at 15° C., 0·9260; refractive index, 1·4654 at 40° C.; viscosity in Engler's viscosimeter, 16·52 at 20° C.; iodine value, 70·6; saponification value, 187·9; Hehner value, 95·6; Reichert-Meissl value, 0·8; acetyl value (Benedikt-Ulzer), 23·5; and unsaponifiable matter, 0·17 per cent. The fatty acids became thick and viscous when dried at a moderately high temperature, whilst at a higher temperature they were converted into a sticky, gum-like mass. The oil, too, behaved in a characteristic manner when heated to 240°—245° C., being suddenly transformed into a gelatinous mass, whilst the temperature meanwhile became spontaneously higher. When a larger quantity (1 kilo.) of the oil was used, the spontaneous heating became so great that the gelatinised oil took fire. On heating the oil for a short time at 240° C., and taking precautions to prevent the temperature rising above 250° C., a tough gum-like mass was left, which was soluble in none of the known solvents. This product did not resinify on exposure to the air, but remained elastic.—C. A. M.

Owala oil. K. Wedemeyer. Chem. Rev. Fett- u. Harz-Ind., 1906 **13**, 210—211.

THE seeds of *Pentaclethra macrophylla*, a tree growing on the west coast of Africa, are termed "Owala" by the natives. They vary in weight from 8 to 20 grms., and have the flat oval shape of a fresh-water mussel. One kilo. of the fruit yielded, in the mean, 20·6 per cent. of shells and 79·4 per cent. of kernels. The whole fruit was found to contain 30·4 per cent. of oil and 29·39 per cent. of proteid matter, whilst the kernels alone gave, on extraction with ether, 41·6 per cent. of oil and left 48·25 per cent. of proteid matter. The pale yellow oil, which, save for a slight deposit, was fluid at the ordinary temperature, had an aromatic smell and a pleasant flavour with a bitter after-taste. In the author's opinion, it would be suitable as a food after being refined. It became semi-solid at 4° C. The following analytical values were obtained:—Sp. gr. at 25° C., 0·9119; refractometer reading (Zeiss) at 40° C., 59·2°; acid value, 9·0; saponification value, 186·0; Reichert-Meissl value, 0·6; Hehner value, 95·6; iodine value, 99·3; melting point of fatty acids, 53·9° C.; solidification point of fatty acids, 52·1° C.; acetyl value, 37·1; and unsaponifiable matter, 0·54 per cent.—C. A. M.

Oils or fats, notably those resembling karité butter, Treatment of ——, to obtain a gummy material. Soc. Rocca, Tassy, and de Roux. Fr. Pat. 364,368, March 12, 1906.

The oil or fat is left in contact with a strong acid (*e.g.* 5 per cent. of sulphuric acid of 63° B.) for a sufficient time, say two days, at a temperature of about 50° C., and the gummy matter then separated by the addition of, say, three times the volume of hot water. Claim is also made for the special gums thus obtained from karité and shea butters, and other analogous fats. They can be purified by washing with water and with a solvent for fats, or by other suitable means.—C. A. M.

Oils and similar organic substances; [Electrical] Hydrolysis of ——. E. T. B. Simpson. Fr. Pat. 364,587, March 26, 1906. Under Int. Conv., Jan. 2, 1906.

The oils, &c., are submitted to the action of an electric current whilst being simultaneously acted upon by heat (superheated steam) *in vacuo* or under reduced pressure. It is stated that the process is accelerated, and that the products are purer than those obtained by the ordinary methods. It is preferred to plunge both electrodes into the oil, and to connect them with a dynamo or with an electric battery, the temperature not being allowed to exceed 270° C. during the process. C. A. M.

Wax substitute to be used in the production of coloured papers; Manufacture of ——. F. M. Winter. Fr. Pat. 364,069, March 13, 1906.

Neutral or slightly alkaline sulpholeates or sulphonated fats are melted with oleic acid or fatty acids of high melting point, and with hydrocarbons of high molecular weight. The resulting product gives with hot water and without saponification a lasting emulsion which does not injure delicate colours.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(*Continued from page* 857.)

(*A.*)—PIGMENTS, PAINTS.

Paints; U.S. Production of mineral and lead . U.S. Geol. Survey Oil, Paint. and Drug Rep., Aug. 27, 1906. [T.R.]

The materials grouped under the head of mineral paints include such iron ores as are ground and used in the manufacture of metallic paints; ochres and other clays rich in iron, which are used for the yellow and brown pigments (ochre, umber, sienna), and which are occasionally roasted to give red pigments; and fine-grained slates and shales of attractive colours, which are ground for use as paints.

The following table shows the production of the various mineral paints in 1905 as compared with 1904:—

Kind.	1904. Short tons.	1905. Short tons.	1904 Value	1905 Value
			$	$
Ochre	16,826	13,402	110,602	126,351
Umber }	522	689	12,960	17,004
Sienna }				
Metallic paint ..	19,857	16,489	204,377	176,722
Mortar colour ..	7,525	10,494	84,426	120,430
Zinc white	63,363	68,603	4,808,482	5,520,240
Slate	5,370	5,181	53,709	44,108
Other pigments ..	2,786	10,344	27,360	240,318
Totals.....	115,699	125,202	5,301,916	6,245,173

The imports of ochre in 1905 aggregated 10,632,481 lb., valued at $92,553, of which 10,616,496 lb., valued at $91,673, were imported in a dry state, and 15,985 lb., valued at $880, were ground in oil.

The imports of umber in 1905 aggregated 2,587,284 lb., valued at $21,224, of which 2,580,507 lb. were recorded as "dry-crude and powdered, washed or pulverised," while 6783 lb. were ground in oil. The relative values of the dry umber and umber ground in oil are not given.

The imports of sienna in 1905 aggregated 1,740,995 lb., valued at $26,324, of which 1,737,909 lb., valued at $26,097, were imported in a dry state, while 2886 lb. were ground in oil.

France is the largest producer of ochre, and its output usually amounts to more than the combined production of the United States and Great Britain, which usually rank second and third in the output of these pigments. In 1904, the latest year for which statistics are available, France produced 58,520 short tons of ochre, while the output of Great Britain was 17,976 tons.

Lead paints and Venetian red.—The pigments which have been noted are true mineral paints, made directly from a crude mineral. In the following table the production of certain other paints in 1905 is given:—

	Quantity.	Value.
White lead—	lb.	$
In oil	125,534,000	7,577,437
Dry	147,818,000	8,261,212
Sublimed lead	13,954,000	732,585
Zinc lead	13,558,000	474,530
Red lead	32,756,000	2,049,888
Litharge	39,756,000	2,307,233
Litharge, orange mineral	39,756,000	2,307,233
Venetian red	13,758,000	137,541

The imports of the above-named products in 1905 were as follows:—White lead, 597,510 lb., valued at $34,722; red lead, 704,402 lb., valued at $26,553; litharge, 177,757 lb., valued at $4139; and orange mineral, 628,003 lb., valued at $31,106.

Carbon; Process and apparatus for the manufacture of amorphous ——. J. Machtolf. Fr. Pat. 364,034, March 10, 1906. Under Int. Conv., March 13, 1905.

The amorphous carbon is obtained by the dissociation of hydrocarbons, previously heated, under suitable pressure, by means of a spark. Almost any gaseous hydrocarbon may be used, but the best qualities of carbon are obtained from ethylene, or from ethylene mixed with acetylene. Just before sparking the gas, a little air may be admitted to it to increase the heating effect. The carbon obtained is collected by suitable means, and used as pigment, or compressed into pencils for arc-lamps, &c. The hydrogen liberated is also collected in a suitable holder.—A. G. L.

(1) From Port Dickson (2) From Jempol

It will be seen that the specimens exhibit considerable differences in chemical composition and properties, but they were all partially soluble in alcohol, and completely soluble in oil of turpentine, forming fairly light-coloured varnishes.—A. S.

United States Patents.

Turpentine; Digester for extracting spirits of ——. F. D. McMillan, Atlanta, Ga. U.S. Pat. 827,554, July 31, 1906.

The digester consists of a vertical cylindrical vessel provided with inlet and outlet pipes, and a perforated false bottom at its lower end. Inside the vessel is suspended a sectional retort constructed of movable plates, and open at the top and bottom. The size of the retort may be increased by means of adjusting screws and rods passing through stuffing-boxes in the side of the outer vessel. The retort is suspended from turnscrews fixed to the top of the vessel.—W. P. S

Turpentine, rosin, &c., from wood; Process of obtaining ——. W. K. Hale, Catskill, N.Y., and C. W. Kürsteiner, Englewood, N.J. U.S. Pat. 828,474, Aug. 14, 1906.

The wood is subjected to the action of hot water in a suitable bath or vessel. The initial temperature of the water should be about 130° F., and it is raised slowly to about 210° F. Water is added to the bath from time to time to cause the oils which rise to the surface to float or flow off into a still. The contents of the latter are raised to a temperature of about 215° F., and the volatile matters condensed. Finally, the residue in the still is heated to a higher temperature in order to separate the rosin oil from the rosin, whilst the water may be removed from the water-bath, and the wood subjected to destructive distillation.—W. P. S.

French Patent.

Resinous oils; Process of making resinous products easily soluble in dilute alkalis from ——. Chem. Fabrik Flörsheim, Dr. H. Noerdlinger. Fr. Pat. 364,398. March 19, 1906. Under Int Conv., March 20, 1905.

See Eng. Pat. 8590A of 1905; this J., 1906, 529.—T.F.B

(C.)—INDIA-RUBBER, &c.

English Patents.

Rubber; Manufacture of tubes, bars, felt, cable coverings, or the like from regenerated ——. B. Roux, Paris. Eng. Pat. 16,389, Aug. 11, 1905.

Claim is made for apparatus in which waste powdered rubber is regenerated by means of heat and pressure. In the manufacture of tubing, for instance, the waste rubber is placed in a cylinder into which a piston can be driven by hydraulic or other pressure. Near the closed end of the cylinder is the opening of a tube of the required diameter, and in the centre of this is a metal core. The rubber is forced by the pressure into the annular space between this core and the tube, the heat required for the regeneration being supplied by an apparatus on the outside, whilst lower down there is a cooling device to bring the rubber tubing to the required temperature before its removal. Means are also provided for the injection of some lubricating fluid, or of chalk, &c., into the tube. Cables, &c., are coated with rubber by letting them take the place of the core, and when a solid rubber roll is required, the core is omitted, and the drawhole made of any shape desired. If necessary, the material may be mixed with a volatile or vulcanisable solvent. For felting the rubber, the powder is driven through longitudinal holes in a mandrel, so as to form filaments, which then striking on suitable obstacles become interwoven or felted together.—C.A.M.

Rubber; Method of and means for purifying crude or reclaimed ——, *applicable as well to gutta-percha and similar materials.* F. C. Hood, Boston, U.S.A. Eng. Pat. 3416, Feb. 12, 1906.

See U.S. Pat. 821,717 of 1906; this J., 1906, 646.—T.F.B.

French Patents.

Caoutchouc, gutta-percha, and analogous substances; Process for obtaining —— *in a pure state.* B. Graetz. Fr. Pat. 363,339. Feb. 16, 1906. Under Int. Conv., Feb. 1, 1906

Substances containing caoutchouc are extracted, at a temperature below the melting point of caoutchouc, with aniline or an alkyl-aniline, which dissolves resinous, fatty, and waxy matters. Water, acetone, or an alcohol may be added to the aniline to depress its boiling point. In the case of substances containing gutta-percha, the latter is dissolved, along with the resins, by the hot aniline, but can be recovered by cooling, or by precipitation with water, acetone, or an alcohol.—A. S.

Caoutchouc; Process for the production of pure —— *from substances containing it.* B. Graetz. Fr. Pat. 363,340, Feb. 16, 1906. Under Int. Conv., Feb. 2, 1906.

The caoutchouc and resins are extracted by a suitable solvent, such as carbon bisulphide, benzene, oil of turpentine, or ether, and the caoutchouc is precipitated from the solution by methyl, ethyl, or amyl alcohol, or acetone. —A. S.

Rubber; Process for the preparation of —— *for vulcanisation.* B. Graetz. Fr. Pat. 363,341, Feb. 16, 1906. Under Int. Conv., Feb. 2 and Feb. 5, 1906.

The rubber is prepared for vulcanisation by treating it with substances which dissolve out the resins, but leave the caoutchouc unaffected. For example, the rubber is heated, under a reflux condenser, with amyl alcohol, to which water has been added for the purpose of lowering its boiling point.—A. S.

Elastic substance analogous to caoutchouc, and its process of manufacture. L. Roland. Fr. Pat. 364,075, March 13, 1906.

A substitute for caoutchouc is prepared by the action of chromic acid, or a chromate, on a mixture of gelatin and glycerin in a liquid condition. For example, 8 kilos. of glue and 6 kilos. of gelatin are soaked in cold water for from 2 to 24 hours, and well mixed with about 15 kilos. of glycerin at 28° B.; the mixture should weigh from 30—35 kilos. A hot solution of 560 grms. of potassium bichromate and 140 grms. of sodium bichromate in 1200 grms. of water is then added. On cooling, an elastic material is obtained, which is said to be specially suitable for the manufacture of tyres.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 858.)

Tanning materials of the Sudan. Bull. Imp. Inst., 1906, **4**, 95—97.

FOUR products used as tanning materials by the natives in the Sudan have been examined, *viz.*, the barks of "Mudus" (*Parkia filicoidea*) and of "Abu Surug" (*Prosopis oblonga*), and the pods and bark of the "Sant" tree (*Acacia arabica*). The following results were obtained, the tanning experiments being made on "limed" calf-skin:—

	Mudus bark	Abu Surug bark.	Sant bark	Sant pods.
Moisture, per cent.	12·2	11·1	11·5	10·6
Ash, per cent.	6·1	2·7	6·8	3·7

—A. S.

Quebracho tannin. II. M. Nierenstein. Collegium, 1906, 141—142. (See this J., 1905, 907.)

ONE grm. of quebracho tannin was dissolved in 500 c.c. of water, and the solution, in one case mixed with 100 grms. of sodium acetate (see Perkin and Yoshitake, Chem. Soc. Trans., 1902, **81**, 1164), and in another case without such addition (see Etti, Monats. Chem., **2**, 548), was cooled with ice, and a 0·5 per cent. solution of diazobenzene chloride added drop by drop until a turbidity was no longer produced. After standing for 24 hours, the deep red precipitate was filtered off, and repeatedly boiled with acetone, the colour changing to light red during this treatment. The azo compound thus obtained was insoluble in alcohol and other solvents, and did not melt below 360° C. It contains 52·2—59·9 per cent. of carbon, 2·97—4 per cent. of hydrogen, and 13·17—14·55 per cent. of nitrogen. By extracting the reaction product with absolute alcohol, and evaporating the solution, a red powder was obtained, which had all the properties of a catechol-tannin, but was optically inactive, whereas quebracho tannin has, according to Trimble, a rotatory power of from + 11° to + 26°. This indicates that the optical activity of a tanning substance may be due to the accompanying sugar, rather than to the tannin.—A. S.

Chromed skin; Absorptive properties of —— for tannin. J. T. Wood and W. E. Holmes. Collegium, 1906, 301—303.

THE authors confirm Kopecky's statement (Collegium, 1906, 100) that chromed box-calf shavings, neutralised, and washed free from soluble matter, when pressed free from excess of water absorb tannin better than specially prepared dried chromed powder, since the drying seems to make it impossible to completely wet down the skin-fibres. Five grms. of such shavings, containing 78 per cent. of water and 7·4 per cent. of ash (5·7 per cent. of chromic oxide), were stirred for an hour with 500 c.c. of a solution of Hastings' tannin, and left for 15 hours. After straining off the leather, the soluble matter in the filtrate was determined. This deducted from the total soluble matter, after allowing for the moisture contained in the added shavings, gives the matter absorbed by the skin. Since chromic oxide does not absorb tannin, the results were calculated on dry ash-free skin, and plotted on a curve, A, side by side with a second curve, B, representing amount of tannin absorbed per 100 parts of dry skin substance free from ash, from von Schroeder and Passler's figures for pure skin substance (v. Schroeder's

Gerberei Chemie, p. 396; this J., 1903, 1138). The curves show that the absorption by chromed skin, though reaching a lower maximum than that of pure skin, is much more regular.—S. R. T.

Leather formation; Theory of ——. W. Fahrion. Collegium, 1906, 286—287.

LUMIERE and Seyewetz (this J., 1906, 704) have observed that when phenol is employed as a developer in photography, the presence of air is necessary to render the gelatin completely insoluble. They argue that oxygen must play a similar part in the process of tanning. The author points out that he has already (this J., 1903, 919) advanced this theory. It is not the tannic acids, but their primary oxidation products that are in the first instance concerned in the formation of leather, these being of the nature of peroxides, and containing available oxygen, which they give up to the skin fibre during the tanning. Heating or a prolonged contact with water changes these peroxidised compounds into phlobaphenes, which contain no available oxygen. Hence, the ready formed primary oxidation products are only very incompletely used up in many cases, such as liquor tanning [Brühengerbung], but a new formation of primary oxidation products may take place during the drumming and other processes in which air is present. In layer tanning, where the access of air is much more completely excluded, no oxidation can take place, but in this case the ready formed oxidation products are completely used up, since the extraction takes place at ordinary temperature and in the presence of the skin fibre.

It is known that there is a close relationship between quinones and peroxides, and hence the observation of Lumière and Seyewetz (this J., 1906, 496), that an aqueous solution of quinone has the power of rendering gelatin insoluble in the absence of air, may be regarded as a confirmation of the author's oxidation theory.

The case of sumac, which shows no tendency to oxidation, may be urged against this theory, but the explanation is, according to the author, to be found in the fact that the tannin in this case is entirely derived from leaves which offer a large surface to the air. The supposition that the tannic acid is already oxidised is confirmed by the oxygen content of 44 per cent. against 36 in the case of oak tannin. In Turkey, sumac is used in the following way:—The skins, having been made into water-tight bags with the flesh side inwards, are filled with water and a quantity

of sumac leaves, and hung up, when the tanning proceeds of its own accord in a manner somewhat analogous to that of pit tanning.—S. R. T.

Leather drying; Principles of ——. F. H. Haenlein. Lecture given before the meeting of the Union of the Leather Makers of Saxony held in Dresden, Oct. 23, 1905. Collegium, 1906, 212.

By means of a series of experiments, the author shows that a current of moderately warm air should be employed for drying leather, for if the temperature be raised above a certain point the quality of the leather is damaged. The maximum temperature that can be employed without danger depends upon the kind of leather, varying from about 20° C. to 35° C., although, in certain factories, still higher temperatures are successfully used. A mistake commonly made in the arrangement of temperature and ventilation is that the latter is either too great or too small. If the drying process be badly managed, the leather will be unequal. Thus, for instance, if too quickly dried, the upper layers often become hard, whilst the inner ones are still wet, and the leather which is apparently dry gradually becomes damp when kept, owing to the water in the interior working its way to the surface.

The water content of non-fatted tanned leather may be taken at about 18 per cent., whilst in fatted leather it is somewhat lower, namely, about 15·4 per cent.

The variations which take place on account of the varying condition of the atmosphere are about 2·5 per cent. in fat-free, and 2 per cent. in fatted leathers. Fat-free air-dried leather may contain as much as 20·5 per cent. of water during exceptionally damp weather, and under contrary conditions as little as 15·5 per cent.

In order to avoid differences between buyer and seller it is advisable not to use a store which is subject to irregular conditions as to temperature and ventilation.

Experiments by Von Schröder have shown that the so-called horn leather can take up and hold more water than ordinary tanned leather, ranging from 19 to 28 per cent. So far as is at present known, the power of retaining water gradually diminishes with the degree of tanning.

Experiments carried out with Valdivia leather (Collegium, 1902, 5—6) gave the following results:—

Percentage of water.

	Valdivia leather	German leather according to different systems of tanning		
		Rhenish	New	North.
Maximum	21·7	20·4	19·8	18·2
Mean	19·5	18·0	17·8	16·8
Minimum	15·1	15·0	14·5	14·2
Variation	6·6	5·4	5·3	4·0

The influence of the tannage is much more marked with chrome leather, the water content being in non-fatted leather about 6½ per cent. higher than in bark-tanned leather. The maximum is quite 10 per cent. higher and occasionally reaches 29 per cent. The variations are also correspondingly greater, being about 9 as against 5 per cent.—S. R. T.

English Patents.

Skins; Process for treating —— for the manufacture of fur. A. Granville, London. Eng. Pat. 16,887, Aug. 21, 1905.

The skins as imported are soaked for about 10 hours in cold water, and then rinsed, and soaked for two or three hours in dilute hydrochloric acid (say 5 to 7 per cent.), after which they are drained, rinsed in alkaline water, drained, scoured cold, tanned, dressed, and dyed. Finally, the upper wool or hair is removed by any suitable means, leaving intact the short, curly underlayer of wool upon the skin, the resulting fur having the appearance of astrachan, especially in the case of lambs' skins and the like.—C. A. M.

Leather; Process of hardening ——. D. Bryan, Liverpool. Eng. Pat. 1787, Jan. 24, 1906.

The leather is steeped in cold water for about 24 hours, then slowly dried in the air for about the same time, and, after being hammered, left in a dry place to set hard. —C. S.

French Patents.

Leather; Process for the manufacture of a product for the impregnation of ——. J. A. Jensen. Fr. Pat. 363,588, Feb. 24, 1906.

For rendering leather impervious to water, it is impregnated with a composition prepared by adding to dégras (4 parts), a mixture of rosin and shellac in scales, for example, "linoleum cement" (14 parts), and treating the resulting mass with any suitable lac (4 parts), which has been previously mixed with a solution of rosin (1 part), and a small quantity of "carbolineum." The product is rendered more or less liquid by adding varnish or the like (16 parts).—A. S.

Gelatin; Process for rendering —— more resistant to the action of moisture and of heat. E. Ohr and O. Schlegel. Fr. Pat. 363,592, Feb. 24, 1906.

Gelatin and objects made of the same are rendered more resistant to the action of moisture and of heat by coating them with a kind of varnish composed entirely or in part of ether, alcohol, amyl acetate, benzene, camphor, oil of turpentine, and lavender oil, with pyroxylin, shellac, sandarac resin, borax, dammar resin, and similar substances.—A. S.

Catgut threads; Process for sterilising ——. H. Schmidt. Fr. Pat. 364,535, March 24, 1906.

See Eng. Pat. 7825 of 1906; this J., 1906, 770.—T. F. B.

Norgine [Ammonium tangate]; Process for obtaining soluble —— in a dry and neutral condition. Soc. Franç. La Norgine. Fr. Pat. 361,498, May 23, 1905.

Tang acid, obtained according to processes previously described (Fr. Pats. 278,749, 278,785, 278,862, 283,432, and 283,433 of 1898, and 287,964 of 1899; see Eng. Pats. 12,275 and 12,277 of 1898; this J., 1898, 794), and dried as far as possible by heating and pressing, is subjected to the action of ammonia gas in order to produce directly norgine or ammonium tangate, which is obtained, after drying, as a neutral powder, completely soluble in water. (Compare Fr. Pat. 358,398 of 1905; this J., 1906, 233.)—A. S.

Celluloid, horn, &c.; Decoration of —— with metallic deposits of gold, silver, &c. L. Schwob and G. H. Dilette. Fr. Pat. 364,559, March 24, 1906. XIX., page 906.

FRENCH PATENTS.

Manure; Manufacture of a ——. V. D. Steyaert. Fr. Pat. 364,272, March 15, 1906.

FÆCAL liquids and matters, together with finely-powdered vegetable matter, are submitted to fermentation, at first anaërobic and then aërobic. The mass becomes heated, and in the course of several months dries up "progressively and spontaneously," so as to form a powder. It is stated that a portion of the nitrogen present is converted into ammonia and nitric nitrogen, and that the germinative power of the spores present (including "spores d'ustilaginées") is destroyed.—E. S.

Drying-drum [for manures]. E. Vial. Fr. Pat. 364,291, March 16, 1906.

A HORIZONTAL metal cylinder is supported on roller-wheels, and rotated in a casing. It is provided with manholes on either side for the introduction and removal of the materials treated, which are dried by a current of heated gas entering through an axial opening at one end of the cylinder, and leaving, along with the vapour given off, by a similar opening at the other end. A shaft, driven by mechanism from without, passes axially through the cylinder, and is provided with a series of radial arms, attached to the shaft, and connected at intervals by rods. The arms carry at their extremities, and nearly touching the inner surface of the cylinder, a number of doubly inclined sheet-iron scrapers, each of which extends the whole length of the cylinder. The arms are rotated independently of the cylinder, and have additional scrapers at each end to clean the end plates of the cylinder. To further assist in agitating the contents of the dryer, a number of chains are fastened at one end to the scrapers, and, after passing round the connecting rod on the next arm, are attached to the third arm at the point where it is fixed to the shaft.—W. H. C.

Fertiliser and method of manufacturing it. W. B. Chisolm. Fr. Pat. 364,460, March 21, 1906.

GERMAN PATENT.

Potash minerals, insoluble and soluble with difficulty; Process for the utilisation of —— for fertilising purposes. C. Plock and H. Mehner. Ger. Pat. 167,246, March 17, 1904.

POTASH minerals, insoluble or soluble with difficulty, especially "Phonolith" waste, are utilised in place of sand, as an addition to molten Thomas slag.—A. S.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 859.)

Starch paste; Influence of certain mineral compounds on the liquefaction of ——. J. Wolff and A. Fernbach. Compt. rend., 1906, **143**, 363–365.

To ascertain the influence of bases on the viscosity of starch paste heated under pressure, the authors have made use of starch either thoroughly washed with distilled water, or treated with 0·1 per cent. hydrochloric acid solution and subsequently washed with distilled water. The starch was converted into a paste, treated with the basic substance, and then heated under pressure. Alumina is found to have no influence on the viscosity of the starch paste, which, however, is increased to about the same extent by magnesia, lime, ammonia, or sodium carbonate. If the paste prepared from an impure starch containing bases be made approximately neutral to methyl orange by the addition of a strong acid, such as sulphuric or phosphoric acid, it readily loses its viscosity when heated under pressure, the presence of the salts formed with the acid being without influence. With starch free from lime, the viscosity of the paste is considerably changed by a very slight modification of the reaction on either side of neutrality towards methyl orange; for instance, the viscosity of a 5 per cent starch paste is observed to increase or diminish if sodium carbonate or sulphuric acid be added in the proportion of 0·16 part per 100 parts of starch.—T. H. P.

Starch paste; Influence of acids, bases, and salts on the liquefaction of ——. A. Fernbach and J. Wolff. Compt. rend., 1906, **148**, 380—383.

SALTS which are neutral to methyl orange exert no influence on the loss of viscosity suffered by starch paste heated under pressure (calcium sulphate, magnesium sulphate, sodium dihydrogen phosphate); salts alkaline to methyl orange (disodium hydrogen phosphate) retard it considerably, and mere traces of alkalis prevent it altogether. No doubt the liquefaction of starch paste by diastase is subject to similar influences.—J. T. D.

Manganese; Determination of small quantities of ——, *and a new method of formation of glycerose.* N. Tarugi. XXIII., page 911.

ENGLISH PATENT.

Sugar solutions obtained from wood that contains tannin; Process for facilitating the fermentation of ——. A. Classen, Aix-la-Chapelle, Germany. Eng. Pat. 22,709, Nov. 6 1905. Under Int. Conv., Nov. 21, 1904.

SEE Ger. Pat. 161,644 of 1904; this J., 1905, 1078.—T. F. B.

UNITED STATES PATENTS.

Sugar from bagasse; Method of recovering ——. C. C. Cromwell, New Orleans, and F. T. Maxwell, Baton Rouge, La. U.S. Pat. 828,198, Aug. 7, 1906.

THE scums from the settling tanks are diluted with water, calcium hydroxide is added, and the mixture steamed, and allowed to settle; the unsettled juice is also diluted, treated with calcium hydroxide, steamed, the products mixed, and filter-pressed. The filter-press cake is washed, and the crushed cane or bagasse saturated with the wash-water; the juice is then expressed from the bagasse, and evaporated.—W. P. S.

Caramel, Production of ——. T. D. Lichtenstein, Silvertown. U.S. Pat. 829,478, Aug. 28, 1906.

SEE Eng. Pat. 28,547 of 1904; this J., 1906, 130.—T. F. B.

FRENCH PATENTS.

Diffuser [Sugar manufacture]. F. Closs. Fr. Pat. 364,223, March 13, 1906.

THE apparatus consists of a vertical cylinder in which is suspended at about half its height a perforated plate. This plate is placed horizontally, and concentrically to the sides of the cylinder, and its object is to prevent the accumulation or heaping of the beetroot chips. When the diffuser is emptied, the plate is tilted by means of a chain so that the chips above the plate fall towards the man-hole at the bottom of the cylinder. One or more of these plates may be provided in each diffuser, or annular rings may be used in their place.—W. P. S.

Beet chips and other moist substances; Mechanical drying of ——. J. C. F. Lafeuille. Second Addition, dated March 14, 1906, to Fr. Pat. 334,411, Aug. 4, 1903.

THE drying apparatus consists of a cylindrical vessel, inside which is a rotary strainer. A current of hot air is passed into the end of the two cylinders, the current being divided into two portions by means of a diaphragm provided with openings fitted with regulators. One current is directed into the rotary strainer, and the other passes between the latter and the outer casing. The rate of drying is thus increased, and the chips do not adhere to the strainer.—W. P. S.

Sugar ; Plant for the crystallisation of ——. V. Glovinkovski. Fr. Pat. 364,422, March 20, 1906.

THE installation consists of three cylindrical vessels each of which is divided into horizontal compartments by a number of plates. The plates are pierced by pipes which are bent in opposite directions below the plates, thus causing the liquid to be mixed as it flows from one compartment to another. An internal pipe rises from near the bottom of the first cylinder, and enters the top of the second, which in turn is in connection with the third cylinder by means of a pipe entering the sides of the two cylinders at about half their height, the ends of the pipe reaching to the bottoms of the cylinders. Means are provided for cutting off the connection between the first and second cylinders. Inside the third cylinder is a ball-float, which actuates the valves on pipes connecting the cylinders with vacuum and force pumps respectively. When the third cylinder is full of liquid, air under pressure is admitted, and at the same time the first and second cylinders are automatically placed in connection with the air-pump. The ball-float falls when the third cylinder is emptied, and the process, and current of the liquid, are changed to the opposite direction.—W. P. S.

Sugar [for brewing] ; Process for denaturing ——. P. Landouzy. Fr. Pat. 364,072, March 13, 1906. XVII., page 901.

Yeast ; Division of the cell-nucleus of pressed ——. W. Swellengrebel. Ann. de l'Inst. Pasteur, **19**, 503; Z. Spiritusind, 1906, **29**, 231.

IN order to observe the process of division of the cell-nucleus, the pressed yeast is grown on must-gelatin for 24 hours ; a few cells are then placed on a drop of gelatin solution which is semi-fluid at the temperature of the room, and the mixture is spread on a cover-glass. This glass is then placed, without drying, into a fixing solution, the most suitable mixture being composed of water, 20 parts ; alcohol, 3 ; formaline, 3 ; and glacial acetic acid, 0·5 part. For staining the nucleus the fixed preparation is steeped for three hours in a 10·1 per cent. solution of acetic acid, and is then placed in a solution of the dyestuff, 3 parts in 200 of water, where it is allowed to remain for 12—18 hours, finally being mounted in xylol-balsam. The author gives the following description of the process of division in this variety of yeast : The nucleus, in the quiescent state, is round or slightly flattened, and generally lies close to the vacuole ; a nucleolus is also observable. In the "pro-phase" of nuclear division the contour of the nucleus becomes less distinct, and the chromatic substance splits up into four parts —the chromosomes. The latter are situated in the equator of the nucleus in the form of a ring (the mono-branched phase) ; this is especially apparent in the vigorous budding cells of young cultures. The ring has not a homogeneous structure, but appears to be made up of innumerable and varied elements. The development of the spindle-shaped figure, though only rarely, can be made apparent by staining. The "meta-phase" begins with the division of the chromosomes and the grouping of these into small branches, which are directed on both sides of the ring towards the poles. Finally the chromosomes collect at the two poles (the di-branched phase), but the two polar nuclei are not equal. In the "ana-phase" the migration of one-half of the nucleus into the daughter-cell is observed, but a connecting thread can still be discerned. The completion of the division of the nucleus is not coincident with that of the cell ; it may proceed as far as the meta-phase before any signs of budding are apparent. The nuclear division of pressed yeast shows many points of resemblance to the division of the micro-nucleolus of *Paramœcia*, in which also the daughter nuclei remain united by a connecting thread for a long time after the division.—J. F. B.

Yeast ; Influence of mycoderma on the reproduction and fermentation of ——. A. Kossowicz. Z. landw. Versuchsw. Oesterr., 1906. Z. ges. Brau., 1906, **29**, 406.

PENICILLIUM greatly assists the fermentative action of small quantities of yeast in mineral nutrient solutions otherwise left unacted upon, but the presence of over a million yeast cells is apparently an essential condition. The addition of a few mycoderma cells sets up rapid reproduction and fermentation on the part of a few yeast cells that otherwise remain apparently stagnant. Such contamination by traces of mycoderma or budding fungi is held to account for the difference between the results of Pasteur and Liebig, on which Wildiers seeks to rely, in support of his "Bios" theory, these extraneous organisms being capable of directly assimilating ammoniacal nitrogen without assistance from other substances. (See this J., 1906, 823.)—C. S.

Yeast ; Use of "stone square" —— in the dropping system of fermentation. F. Rogerson. J. Inst. Brewing, 1906, **12**, 518—527.

THE author gives an account of his experiences in the application of "stone square" yeasts to fermentations carried out on the dropping and cleansing system, instead of the ordinary London type of yeast. At first he found considerable difficulty in keeping the yeast in a healthy and normal condition for any length of time. This was found to be due to the fact that the open wooden fermentation vessels of 150 barrels capacity were too large to be conveniently pumped and roused in such a manner that sufficient wort could be continually brought in contact with the yeast, and the cells were starved. When smaller tuns of 40 barrels were used, the wort could be easily manipulated. In working "stone square" yeast on the dropping system, it is desirable to have a certain number of stone squares, and to pass the pitching yeast through these, on the usual stone square system, from time to time. The beers prepared by "stone square" yeasts are remarkable for their freedom from "frets," and their perfect condition, and it is stated that these beers "taste 1 lb. heavier than any other," owing probably to their being saturated with gas.—J. F. B.

Diastases ; A property of ——. J. Duclaux. Compt. rend., 1906, **139**, 344—346.

CATALYTIC actions of weak acids, say of acetic acid, are due not to the whole of the acid present but to the portion electrolytically dissociated, the amount of which depends upon other factors, besides that of the dilution. Similarly, colloids (to which class diastases appear to belong) react in virtue of the variable active part—colloidal ferric hydroxide, for example, $Fe_2(OH)_6$,$mFeCl_3$, in virtue of the ferric chloride present—and this active part depends on many circumstances besides the concentration of the whole. It is very probable, then, that diastases react under similar conditions, and it can only lead to error to assume that doubling the amount of a diastase present in a reaction should necessarily double the effective working concentration.—J. T. D.

Starch paste ; Influence of acids, bases and salts on the liquefaction of ——. A. Fernbach and J. Wolff. XVI., page 898.

Extracts [Brewery] ; A study on —— II. W. S. Smith. J. Inst. Brewing, 1906, **12**, 572—588. (See also this J., 1906, 438.)

ONE of the most important developments in brewery practice in the near future will be the general adoption of grists ground to a state of fine meal. The use of this fine grist necessitates, first, the most careful mashing, and, secondly, scientific and systematic sparging. As regards mashing, attention must be devoted to the manipulation of the

mashing machine and mash-tun rakes, and to the area of the mash-tun. As regards sparging, the principle to be aimed at is a fairly constant ratio of liquor to malt residues. From the first moment of setting the taps, a gradual decrease in the volume of the malt contents begins, and the lowering of the level does not necessarily mean a lower proportion of liquid; a definite and regular rate in the fall of the level should be aimed at. The difficulties of drainage, which have always been associated with fine mashes, can be overcome by good sparging. In the first place, the rate of discharge of water through the sprinkler must be carefully gauged. The main object is to get the water into the finest possible state of sub-division, in order to avoid any definite streams of liquid. For this object the holes should be only 0·032 inch in diameter. The number of holes should increase towards the further end of the sparge-arm, corresponding to the greater path of travel. The exact ratio of sparge-arms to mash-tun area must be determined by experiment in each case. The author gives a table showing the quantity of water delivered per hour by sparge-arms of different lengths and different numbers of holes under different pressures. In actual practice the author finds it an advantage to provide two sets of sparge-arms, one delivering twice as much water as the other in a given time. In this brewery it is the custom to draw off the worts into two or three coppers. The first copper is made up very slowly, using the sparge-arms which deliver only half a barrel of water per minute. After gentle raking and 30 minutes' stand, the second copper is made up twice as rapidly as the first, using sparge-arms discharging one barrel of water per minute. The goods, not being called upon to bear any appreciable weight of liquor at any time, remain buoyant. The gain of extract obtained by fine grinding is about 3 per cent., and most of this increase is in the form of extract which is not easily fermented.—J. F. B.

Wort infection on the cooler and refrigerator. A. C. Chapman. J. Inst. Brewing, 1906, **12**, 549–560.

The author strongly recommends that the cooler and refrigerator rooms should be situated at the highest point of the building, since his experiments prove that at an altitude of 45—60 feet, the air is very much freer from germs than near the ground level. The exposed area of the cooler should also be reduced considerably, and the depth increased to a corresponding extent. The work of cooling the wort should be thrown more on the refrigerator-system than on the cooler, the latter serving chiefly for the aeration of the hot wort. The aeration in the deeper form of cooler recommended should be effected by injecting filtered air through the hot wort, or else by delivering the wort in the form of a spray. The windows of the cooler-room should be fitted with frames, over which linen sheets can be hung on the side from which the wind is blowing, and the linen should be moistened with an antiseptic solution. With ordinary precautions, wort leaving the cooler at temperatures above 140° F. is very nearly sterile, and by far the most numerous cases of infection are to be traced to the refrigerators. Those forms of refrigerator which consist of pipes packed very close together are condemned. Growths of infecting organisms lodge between the pipes, in places where they cannot be touched by a brush. Chemical disinfectants only sterilise the outer layers of these growths, and do not penetrate to the interior. Such growths, being acclimatised to beer wort, are far more virulent than most of the air-borne germs. The cooling surfaces of the refrigerators should be perfectly continuous, and accessible to brushes at every point. The refrigerator rooms should be closely boxed in, and protected from the entry of all but filtered air.—J. F. B.

Vinegar bacteria; Studies on the "quick" vinegar and wine ——. W. Henneberg. Woch. f. Brau., 1906, **23**, 267—272, 277—280, 289—291, 305—307, 321—323, 337—339, and 353—356.

The author has made an exhaustive study of the various species of vinegar bacteria found in the acetifiers of the "quick" vinegar process, and describes three new species of these bacteria and two new species of wine-vinegar bacteria. The species isolated from the "quick" vinegar process were: *B. Schüzenbachi*, *B. orleanense*, and *B. curvum*.

B. Schüzenbachi exists as longish oval cells, sometimes slightly curved; the optimum temperatures for its development are 28°—30° C. on wort-agar, and 25°—27·5° C. in vinegar wort. The films formed on liquids are non-coherent.

B. curvum occurs as oval or elongated cells, with pronounced curvature; the films are non-coherent; the optimum temperature for growth is 30° C.

B. orleanense occurs as spherical cells or elongated rodlets; the films on liquids are nearly always coherent; the optimum temperature for growth is about 30° C.

The new species of wine-vinegar bacteria were *B. xylinoïdes*, which closely resembles *B. xylinum*, and *B. vini acetati*. *B. xylinoïdes* occurs as roundish cells or short or long rodlets; the films are tough, but are distinguished from those of *B. xylinum* by the fact that when grown on wort-agar they are slimy, with specks of yellow, whereas those of *B. xylinum* are hard and yellowish-brown. The optimum temperature for growth is 28°—30° C. The cells of *B. xylinum* are generally elongated and sometimes assume characteristic spiral forms. *B. vini acetati* occurs as round or oval cells, seldom elongated; the films on liquids are non-coherent; the optimum temperature for growth is 28°—33° C.

The various species show different requirements as regards nutrition. The bacteria grow best with a supply of organic nitrogen, and plentiful carbohydrate nutrients; a little alcohol is favourable; beer-wort, beer, and grain-mash are good media. All these species are capable of producing acid from arabinose, dextrose, erythritol, glycerol, and propyl alcohol. All, except *B. curvum*, produce acid from galactose; all, except *B. curvum* and *B. xylinum*, acidify maltose; all, except *B. xylinoïdes*, produce acid from dextrin. Lævulose is acidified only by *B. Schüzenbachi* and *B. vini acetati*; cane sugar only by *B. xylinoïdes*, *B. xylinum*, and *B. vini acetati*. In certain cases a growth of bacteria takes place without the production of acid; in other cases the acid which is produced is consumed. The bacteria are somewhat sensitive to free acetic acid when it is present in the culture medium from the beginning; the presence of 1·5 per cent., however, does not retard growth. The bacteria appear to be able to develop in the presence of alcohol up to a concentration of 10 per cent. The maximum proportions of acetic acid produced in wine-vinegar worts by the various species were: *B. Schüzenbachi*, 10·9 per cent.; *B. xylinoïdes*, 9·3 per cent.; *B. orleanense*, 9 per cent.; and *B. vini acetati*, 8 per cent. Cultures should be started in diluted wine-vinegar worts, and the films should then be transferred to the undiluted wort. The author gives results of experiments on the small and large scale obtained by the use of pure cultures of *B. Schüzenbachi* in "quick" vinegar acetifiers, showing the gradual increase of acid strength up to 11·49 per cent. of acetic acid after 85 days' working.—J. F. B.

Whisky: The distillation of —. P. Schidrowitz and F. Kaye. J. Inst. Brewing, 1906, **12**, 486–511.

The authors describe the apparatus and methods employed in the distillation of whisky according to the "pot still" and "patent still" processes. In Scotland, the method generally followed in carrying out distillation in pot stills is to submit the wash to a preliminary distillation, in which it is separated into an alcohol-free residue, "pot ale," and a distillate containing the whole of the alcohol, called the "low wines." The "low wines" are then re-distilled, and the distillate is collected in three fractions, leaving a non-alcoholic residue called "spent lees." The relative quantities and the alcoholic strengths of the fractions vary according to the character of the "low wines," the judgment of the distiller, and the district. In a typical case (Scotch, all malt) cited by the authors, 3868 galls. of wash yielded 1403 galls. of "low wines" at 66·3 U.P. In the second distillation, 1323 galls. of "low wines" yielded 110 galls. of "foreshots" at 21 O.P., 172 galls. of "whisky" at 19·4 O.P., and 340 galls. of "feints" at 41·5 U.P. The residues from the two distil-

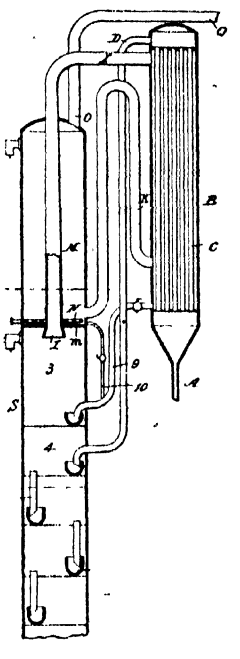
lations consisted of 2645 galls. of "pot ale" and 651 galls. of "spent lees." The foreshots and feints are mixed with the "low wines" of a subsequent distillation. The authors have made analyses of each of these products on similar lines to whisky analyses, and have thereby traced the distribution of the "impurities." The results show that a considerable proportion of these "volatile impurities" is eliminated not only in the "spent lees" of the second distillation, but even in the "pot ale" from the wash distillation. They are highly concentrated in the "foreshots," and occur to some extent in the "feints," and are returned with these fractions to the "low wines" still. In the case referred to, it is shown that of the total "volatile impurities" of the wash, 63 per cent. were eliminated in the "pot ale," 37 per cent. passed into the "low wines," and only 10 per cent. appeared in the whisky. Thus, the authors prove that a very considerable degree of rectification of the spirit is effected by the ordinary "pot still" process. The "patent still" is simply an economical means of effecting continuously in one operation chemical separations of a similar nature to those produced in the "pot still" by two or more operations; the methods are fundamentally identical. Incidentally, it is shown that a partial hydrolysis of the compound ethers, particularly of the heavy oily ethers, takes place whenever a spirit is distilled.—J. F. B.

Alcohol in industry. Eng. and Min. J., Aug. 4, 1906. [T.R.]

As a result of the passage of the Bill allowing the sale of alcohol without the Internal revenue tax in the United States, the Department of Agriculture has decided to publish a bulletin on January 1, 1907, when the law comes into effect, giving a collection of the best obtainable data on the use of alcohol in small engines. For this purpose Charles E. Lucke has been retained by the Department as expert to conduct these investigations in the laboratories of Columbia University. The scope of the work being extensive, it is desired to secure the co-operation of everybody interested, by first giving the fullest publicity to the investigations. Inventors having patents on the subject, or having vaporisers, carburetters or complete engines, are invited to submit the data, or pieces of apparatus to test. These tests will be conducted without any expense, except the transportation of the apparatus. Any data or shipments should be addressed to Prof. Chas. E. Lucke, at Columbia University, New York.

UNITED STATES PATENTS.

Diastatic substance and method of making the same ——. J. Takamine, New York. U.S. Pat. 826,699, July 24, 1906.



A SACCHARIFYING substance, having practically no liquefying action on starch, but a marked saccharifying action on liquefied or gelatinised starch, may be prepared by making an aqueous extract of grains or roots after the whole or part of their starchy constituents has been removed. The extract is subjected to acid fermentation, the precipitate formed is removed, the liquid portion is treated with alcohol, and the precipitate thus obtained collected and dried.—W. P. S.

Strainer-tub for brewers. J. Schneible, Weehawken, N.J. U.S. Pat. 826,891, July 24, 1906

THE apparatus comprises a rectangular tub having a strainer bottom, and a gate or door across one end for the discharge of grains from the strainer. An endless chain conveyor, mounted on wheels in the tub, carries the grains towards the door which is opened automatically by the movements of the conveyor.—W. P. S.

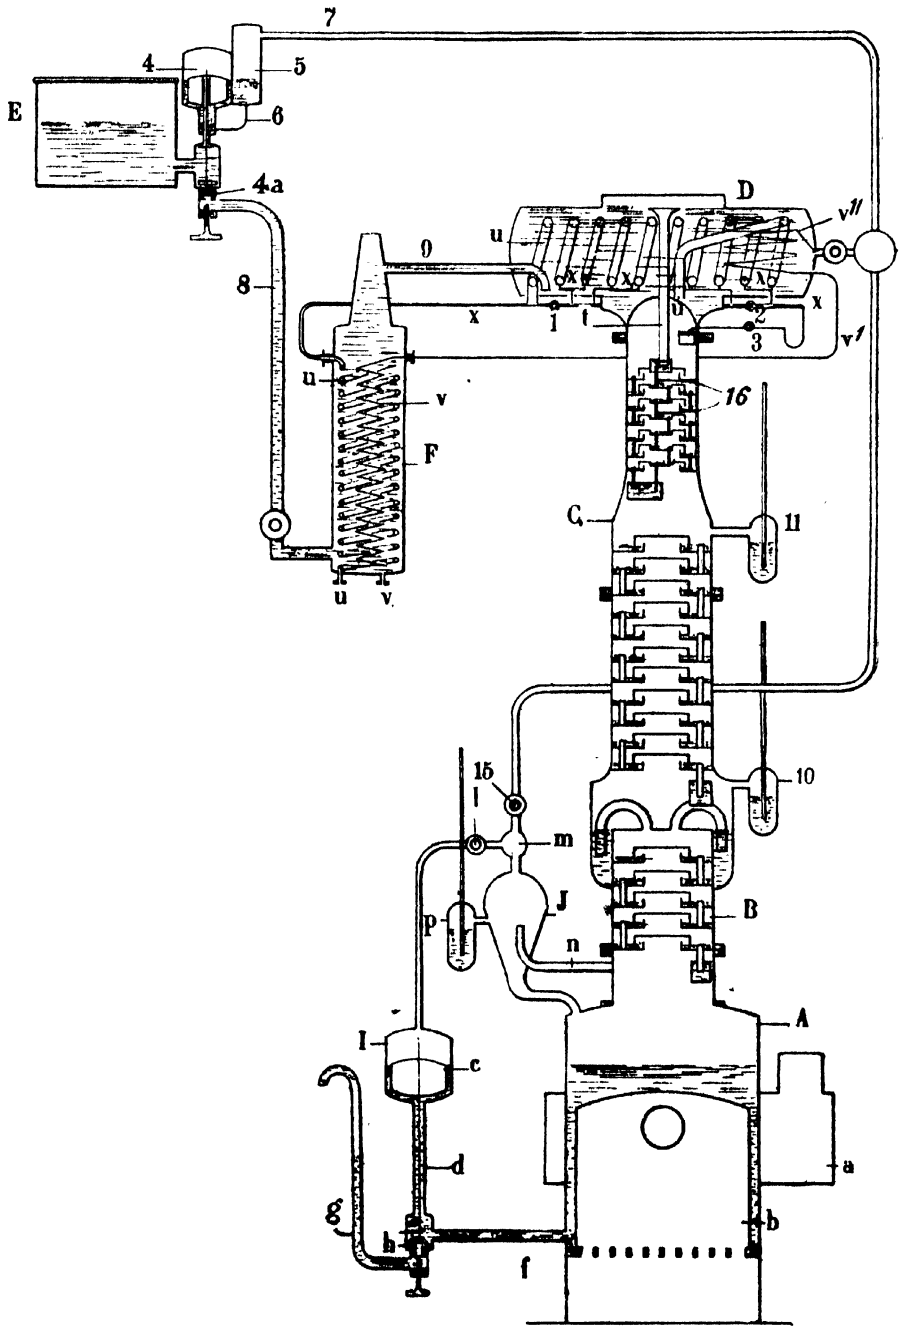
Distillation [Whisky, &c.]; Apparatus for ——. J. J. Brennan, Assignor to T. J. Hines, Louisville, Ky. U.S. Pat. 822,574, June 5, 1906.

THE liquid to be distilled enters through the pipe, A, and passes upwards through the tubes, C, of the heater, B. The warmed liquid leaves, B, by the pipe, D, and enters the compartment, 4, of the still, S. The construction of the still, S, is not claimed, and is described in U.S. Pat. 822,573 of 1906 (this J., 1906, 650), but the claims extend to all else. The liquid flows down the still, and is vaporised by steam, which is passed into the boiler at the bottom of the column, and by the ascending vapours from the liquid treated. The mixed vapours leave the compartment, 3, by the pipe, I, and enter the top of the heater, B. They circulate round the pipes, C, warm the incoming liquid, and are partially condensed. The weak condensate returns by the pipe, 9, into the compartment, 3, of the still, and the uncondensed

vapours pass through the pipe, K, into the "doubler," M. This is a separate chamber at the top of the column, S, from which it is completely isolated by the partition, *m*. In the "doubler," M, the vapours are rectified by the heat from the pipe, I, assisted, if necessary, by the steam coil, N. The vapour escapes by the pipe, O, to the condenser, where high-strength spirit is obtained, and any low-strength condensed liquid is returned to the compartment, 3, of the still, S, by the pipe, 10. It is stated that the use of the "doubler," M, enables a distillate of high strength and purity to be easily obtained.—W. H. C.

Brewers' and distillers' slop; Treating ——. [*Recovery of glycerol, dextrin, lactic acid, &c.*]. C. J. Roehr, Philadelphia, Pa. U.S. Pat. 823,366, June 12, 1906.

THE slop is heated to a temperature of about 200° F., and treated with a solution of sodium silicate, or alkaline solutions of aluminium, zinc, copper, nickel, cobalt, or silver hydroxides. The precipitate formed is separated by means of a filter-press, and the filtrate evaporated to a syrup, which may be added to sizing compounds for textile purposes, dye solutions, pastes, soaps, &c., or if desired, the component parts of the liquid, namely, glycerol, dextrin, and lactic acid, may be separated. Partial neutralisation of the slop, before precipitation, may be effected by passing the liquid over zinc scraps.—W. P. S.



FRENCH PATENTS.

Sugar [for brewing]; Process for denaturing ——. P. Landouzy. Fr. Pat. 364,072, March 13, 1906.

FROM 2 to 10 grms. of tannin, preferably derived from oak-bark, are added to each kilo. of the inverted sugar used for brewing purposes.—W. P. S.

[*Spirit*] *Distilling apparatus.* M. Artaud. Fr. Pat. 364,130, March 1, 1906.

The apparatus consists of a boiler, A, with a very large heating surface, *b*, and surrounded by a flue, *a*; a distilling column, B; a rectifying column, C; a rectifying condenser, D; a condenser, F; and a reservoir for the liquid to be distilled, E. It has also two float-valves, 4, and *d*, controlling respectively the feed and the withdrawal of the exhausted liquid; a vapour chamber, J; and three pressure indicators, *p*, 10, and 11, which serve to indicate how the process is going on in different parts of the apparatus. The liquid from the reservoir, E, flows through the valve, 4, and the pipe, 8, into the condenser shell, F, where it serves to cool and condense the distillate, and becomes heated. It passes on by the pipe, 9, to the condenser-rectifier, D, where it is further heated, and then overflows by the pipe, *t*, into the centre overflow cups, 16, of the column, C. It continues to flow downwards by the

overflow pipes shown, and meets the ascending vapours, and becomes gradually exhausted, so that little else than waste liquor reaches the boiler, A. The ascending vapours bubble up through the bonnets of the columns, B, and C, and finally reach the coil, *u*, in the vessel, D. The lower parts of the turns of this coil are connected, as shown at *x*, to a pipe provided with several taps, 1, 2, 3, so that any desired proportion of the liquid condensing here can be run either to the coil, *u*, in condenser, F, together with the uncondensed vapours, or back to the column, C, by the pipe, 3. The condenser, F, has two coils, one, *u*, for the distillate proper and another, *v* connected by the pipe, *v'*, to the coil, *v''*, in D, which is in direct communication by the pipes, 15, J, *n*, with the boiler, A. When it is desired to test the exhaustion of the liquid in the boiler, A, a portion of the vapour is allowed to pass to the coil, *v*, from the end of which it is collected and tested. The feed of liquid is controlled by the float, 4, in the following manner: the vessel, 5, contains a liquid, and is in communication with 4 by the pipe, 6, and with the boiler, A, by the pipes, 7, 15, J, *n*. When the pressure in the boiler increases, owing to a greater evolution of vapour the liquid in 5 is forced into 4, and the float rises and opens the valve, 4*a*, allowing liquid to enter the still; if the pressure in A falls, the float sinks, and closes the valve. The float, *c*, in the vessel, I, connected by *l*, *m*, J, *n* with the boiler, A, is under the same pressure as A, and when the level of the liquid in A rises, the float, *c*, also rises and opens the valve, *h*, and allows the liquid to escape from A by the pipes, *f*, *g*. When the level of the liquid in A falls, the float, *c*, sinks, and closes the outlet valve.

—W. H. C.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 863.)

(A.)—FOODS.

Cyanogenesis in plants. J. W. Leather. Agric. J. of India, 1906, 1, 220—223.

A SAMPLE of immature sorghum fodder that had proved poisonous when fed to bullocks, was found to yield 1·28 grain of hydrocyanic acid per lb. of the green fodder, and another variety, grown in the same district, furnished 2·5 grains from the leaves, 1·1 grain from the stalks, and 0·25 grain per lb. from the flowers. On the other hand, samples of the first-named variety, left to mature, were harmless, the glucoside (*dhurrin*) present decreasing as maturity advanced. Sun-drying the fodder does not decrease the amount of the glucoside.

All the varieties of the tapioca plant contain a cyanogenetic glucoside, associated with an enzyme which decomposes it with formation of hydrocyanic acid, when steeped in water, though the free acid cannot be detected in the plant. The amount of acid formed ranges from 0·15 to 1·5 grain per lb. of root. The enzyme is destroyed by boiling the root in water, and probably also by frying it in butter (ghee), as is practised in Indian native cookery. When the acid is once formed, it is not dissipated by exposing the sliced root to the air; but, since the acid is soluble in water, there is considered to be no risk of it being left in the tapioca starch.

Hydrocyanic acid has also been obtained by steeping the seeds of Rangoon beans (*Phaseolus lunatus*) and Val (*Dolichos lablab*), as well as from a sample of immature linseed that had poisoned cattle in the Banda district, the amount of acid furnished in this latter case being 1·4 grain per lb.—C. S.

ENGLISH PATENTS.

Milk; Process of treating milk to produce artificial human ——. L. O. Holgate, Leeds, and J. A. Jessop, Shipley. Eng. Pat. 19,521, Sept. 27, 1905.

Two equal quantities of new full milk are taken; one quantity is set aside, whilst the other is skimmed or separated, and the skimmed milk treated with rennet. After removing the curd, the cream which was separated is remixed with the whey, an additional quantity of lactose, or whey, being added if necessary (as seen from an analysis of the milk), and the mixture is incorporated with the quantity of full milk set aside in the first place. The preparation may be dried to a powder by means of any suitable process.—W. P. S.

Malt preparations; Process of manufacturing ——. S. Felix, Dresden, Germany. Eng. Pat. 2584, Feb. 2, 1906.

SEE Fr. Pat. 362,773 of 1906; this J., 1906, 774.—T.F.B.

Coffee; Preparation or treatment of —— J. F. Meyer, Lesum, Germany. Eng. Pat. 6375, March 16, 1906.

SEE Fr. Pat. 364,389 of 1906, following these.—T.F.B.

Butter; Process for the manufacture of artificial ——. D. Müller, Cracow, Austria. Eng. Pat. 12,916, June 2, 1906.

A QUANTITY of neutral fat, such as cocoanut oil, margarine, &c., is heated with whey obtained in the manufacture of cheese. The heating at a temperature of from 40° to 60° C. is continued until the surface of the fat has become covered with a flaky or curdy layer; the aqueous portion is then run off, and the fat worked up in the usual manner. During, or after, the heating process, the fat may receive the addition of milk, cream, and colouring matters.

—W. P. S.

UNITED STATES PATENTS.

Middlings [of flour]; Process of utilising the nutritive properties of ——. S. B. Apostoloff, London. U.S. Pat. 826,824, July 24, 1906.

THE process consists in dissolving out the soluble portion of "middlings" by means of water, adding yeast to the solution, stirring during the resulting fermentation, and then straining the mixture. The strained liquid is added to flour in a kneading apparatus for the purpose of making dough for the manufacture of bread.—W. P. S.

Milk; Process of electrolytically treating ——. [*Separation of proteids.*] C. T. Willson, Amenia, N.Y., Assignor to W. H. Sheffield, Hobart, N.Y., and L. C. Raegener, New York. U.S. Pat. 829,308, Aug. 21, 1906.

SKIMMED milk is continuously passed through an electrolytic tank, and, during its passage through the latter, is subjected to the action of a direct current of electricity. The separated curd resulting from this treatment rises to the surface of the liquid, and is removed.—W. P. S.

Food products; Method of manufacturing ——. A. I. da Silva Braga, Sao Paulo, Brazil. U.S. Pats. 829,253 and 829,254, Aug. 21, 1906.

SEE Eng. Pats. 7896 and 7895 of 1904; this J., 1904, 724 and 619.—T. F. B.

FRENCH PATENTS.

Coffee free from caffeine; Preparation of ——. J. F. Meyer. Fr. Pat. 364,389, March 19, 1906.

COFFEE beans are first subjected in a closed vessel to the action of dry steam at a pressure of 1·5 to 2 atmospheres.

This treatment causes the beans to swell, and loosens the tissue. Ammonia, sulphur dioxide, or hydrochloric acid gas is then introduced into the vessel, and the liberated caffeine extracted by means of suitable solvents such as benzene or, preferably, a mixture of benzene and alcohol. The beans are boiled in the solvent, and, after the removal of the latter, are further subjected to the action of dry steam, preferably in a rotating drum.—W. P. S.

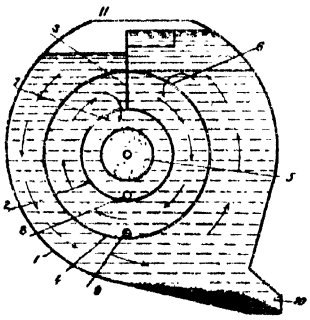
Milk powder; Process of making ——. L. Dupont, H. Passéga, and J. Lehmann. Fr. Pat. 364,565, March 26, 1906. Under Int. Conv., April 4, 1905.

Milk is heated nearly to boiling, and then poured into a receptacle which delivers it on to a horizontal, circular, revolving plate. This plate is hollow, and its interior is supplied with steam under pressure through the hollow central shaft on which it is fixed. The dried film of milk is removed from the plate by means of a screw conveyor and a scraper, the former also serving the purpose of conveying the dried milk to a receiver placed at the circumference of the plate.—W. P. S.

German Patent.

Ligneous substances, such as straw, wood, and the like; Process for working up —— for the preparation of a cattle-food. F. Lehmann. Ger. Pat. 169,880, March 26, 1905.

Straw, wood, or the like is converted into a cattle-food by heating it under pressure with ammonia, expelling the ammonia by steam, and treating the residue with quicklime. The ammonia is recovered for use again in the process.—A. S.



(*B.*)—SANITATION; WATER PURIFICATION.

English Patents.

Water, sewage, and other liquids; Machines for the filtration of ——. A. J. Bell and P. A. G. Bell, Manchester. Eng. Pat. 22,645, Nov. 6, 1905.

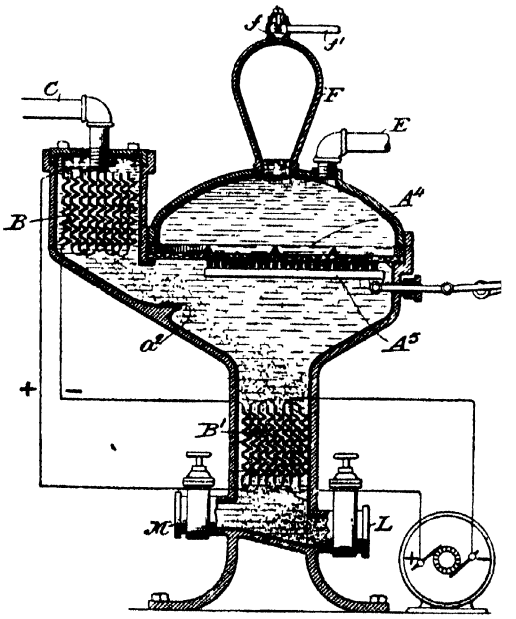
To prevent clogging of the filtering material between the hollow shaft and the faces of the footstep-bearing of the apparatus described in Eng. Pat. 2384 of 1897 (this J., 1898, 178), the patentees now dispense with the ball or roller-bearings, and provide a bearing for the hollow shaft by forming a conical support at the top of the outlet pipe, a case-hardened steel block being inserted therein on which to rest the hollow shaft which carries the radial arms. The base of the shaft is fitted with a curved or conical block having a small recess in which the cone of the outlet pipe rests. The shaft is prevented from moving sideways by means of set screws passing through lugs or projections around the conical support.—W. P. S.

Clarification of fluids [Water]; Apparatus for the mechanical —— W. Rottmann, A. Miller, and P. Filler, Berlin, Germany. Eng. Pat. 7878, April 2, 1906.

The apparatus is shown in a diagrammatic section in the figure, and consists of an outer cylindrical vessel, 1, and an inner eccentrically arranged cylinder, 2, with or without one or more intermediate vessels, 4, and a dividing wall, 3. The water to be clarified either in its natural condition, or after suitable treatment with chemicals and by heat, enters at 11, and flows round the space between 1 and 4 in a "bow" as shown by the arrows. It then enters the space between 4 and 2, through the opening, 6, again flows round, and enters the inner cylinder, 2, through the opening, 7. It is finally drawn off through the filter, 5, which is attached to one side of the vessel. The deposited solids are removed from time to time through the openings, 8, 9, and 10, which are provided with suitable flap doors. The apparatus can be cleaned by reversing the flow.

—W. H. C.

Water; Process for purifying ——. G. J. Lambert, Lille, France. Eng. Pat. 10,080, April 30, 1906. Under Int. Conv., May 3, 1905.

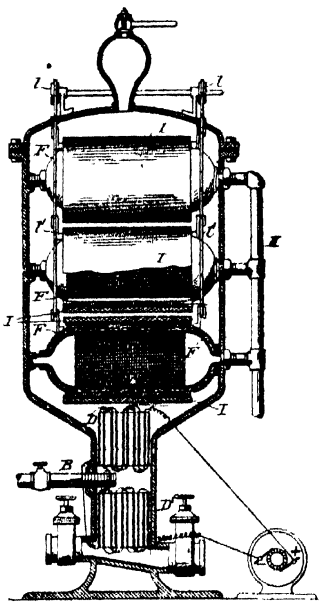


See Fr. Pat. 361,435 of 1905; this J., 1906, 862.—T.F.B.

Water purifying apparatus. E. Declercq, Lille, France. Eng. Pat. 10,206, May 1, 1906. Under Int. Conv., May 13, 1905.

The water enters an upper reservoir through a ball-tap, and then flows through a pipe on to a water-wheel mounted in a lower reservoir. This wheel also carries two series of lifting buckets, one set of which delivers definite quantities of the water from the lower reservoir into a reaction tank, whilst the other series lifts the water, and conducts it to a lime-saturator. The level of the water in the lower reservoir is maintained at a constant level, by means of a ball-tap fixed on a pipe connecting the two reservoirs, which pipe is capable of passing more water than can enter the upper reservoir through the first ball-tap; an overflow pipe is also provided. The shaft of the water-wheel is prolonged on one side in order that it may actuate the stirring device of the lime-saturator, and on the other side so that it may operate a chain of buckets arranged in a tank containing sodium hydroxide solution. These buckets raise definite volumes of the solution, and deliver it into a conduit leading to the reaction tank. An automatic brake may also be fixed on the water-wheel.—W. P. S.

United States Patents.



Liquids; [Electrolytic] Apparatus for treating ——. [*Water purification*]. L. Dion, Assignor to the Americus Electro-Hermatic Co., New York. U.S. Pat. 820,482, May 15, 1906.

THE liquid to be treated is supplied through the pipe, C, and passes between the group of positive and negative electrodes, B, the latter being made in the form of corrugated plates, the negative plates being placed alternately, and nesting with the positive so as to form a sinuous passage-way between them. The purified liquid passes away by the pipe, E, being filtered during its passage through the apparatus by the filter, A^4, which is cleansed by the reciprocating brush, A^5. Any gas liberated passes out through F, which is provided with a discharge pipe, f^1, and a pressure-valve, f. The particles of metal or other substance liberated from the water, fall by gravity, and are deflected by the projection, a^2, so that they are distributed over a second similar series of electrodes, B^1. The particles are further acted upon by the electric current, and are caused to aggregate into masses of larger magnitude, being finally removed through the discharge pipe, L. If the latter is choked, the material may be forced out by opening the hand-hole, M, and introducing a suitable implement.—B. N.

Metals and other substances; [Electrolytic] Apparatus for separating —— from liquids. L. Dion, Assignor to The Americus Electro-Hermatic Co., New York. U.S. Pat., 820,483, May 15, 1906.

THE apparatus is a modification of the one described in the previous abstract (see U.S. Pat. 820,482, above). D and D^1 are the upper and lower sets of electrodes, the liquid being introduced through B, and the purified liquid discharged through H. The liquid, passing from the electrodes, D, flows upward and around a number of horizontally-disposed filter-cages, F, arranged in vertical rows, with filtering material applied to their surfaces. Each cage is provided with a cylindrical brush, I, which is

oscillated by a pin and slot arrangement connecting the brush with a rod, l^1, the latter receiving an up and down motion by the cam, l.—B. N.

Water; Apparatus for purifying ——. L. Sheuerman and J. F. Hand, Des Moines, Iowa. M. N. Baker, administrator of said J. F. Hand. U.S. Pat. 827,399, July 31, 1906.

THE water to be purified is delivered alternately by means of an oscillating receiver into two tanks, above which is placed a reagent tank. A pair of oppositely inclined gutters lead from the reagent tank to the water tanks, and to the top of each gutter is pivoted a bucket for raising a quantity of the reagent to the gutter. The buckets are raised and lowered by the movements of the oscillating receiver. Means are provided for agitating the contents of the reagent tank, and at the bottom of each water-tank is an outlet pipe closed by a valve operated by the receiver. —W. P. S.

Water; Apparatus for purifying and softening ——. S. L. Sheuerman and J. F. Hand, Des Moines, Iowa. M. N. Baker, administrator of said J. F. Hand, deceased. U.S. Pat. 827,400, July 31, 1906.

THE apparatus consists of a vertical cylinder having a conical bottom, and divided into three compartments by means of two vertical partitions. One of these partitions extends from the top of the cylinder to a point near its bottom, and the second reaches from the top to the bottom. A filter composed of a number of plates is fixed at the top of the cylinder between the outer wall of the latter and the second partition, and a pipe, passing through the filter, pierces the top of the partition, whilst the lower end of the pipe reaches nearly to the bottom of the cylinder.—W. P. S.

Water; Process of removing impurities from ——. B. Kniffler, Assignor to the Vera Chemical Co., Milwaukee, Wis. U.S. Pat. 828,938, Aug. 21, 1906.

AN emulsion of saponified rosin is thoroughly mixed with the water, and a quantity of alum is afterwards added. The precipitate formed is said to carry down the suspended particles of solid matter in the water.—W. P. S.

FRENCH PATENT.

Waste waters [sewage, &c.]; Process and apparatus for separating the solid matter contained in ——. Ges. f. Abwässerklärung. Fr. Pat. 364,362, March 5, 1906.

SEE Eng. Pat. 5908 of 1906; this J., 1906, 711.—T. F. B.

(C.)—DISINFECTANTS.

FRENCH PATENT.

Disinfection by means of a new gaseous mixture; Process and apparatus for ——, and for the destruction of parasites and vermin. G. Gauthier Fr. Pat. 364,086, Jan. 23, 1906.

A MIXTURE of powdered sulphur, potassium nitrate, wood charcoal, sodium phenolate, trioxymethylene, and formaldehyde solution is heated in a metal chamber. The gas produced is forced by means of a pump through a cooling vessel and a filter, and is discharged into the room to be disinfected, &c. Pipes are provided by means of which the gas may be pumped back again from the room to the heating chamber, and maintained in continuous circulation until the charge of materials in the chamber is exhausted. —W. P. S.

GERMAN PATENT.

Weeds in corn-fields; Process for destroying ——. F. Guichard. Ger. Pat. 167,529, Feb. 11, 1903.

FOR destroying weeds in corn-fields, the patentee claims the use of ferrous sulphate, which is converted into an extremely light powder containing about one molecule of water of crystallisation by carefully heating it in a current of air. By means of a spraying apparatus, 50 kilos. of this powder can be distributed over 1 hectare of land.—A. S.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page* 865.)

Paper; Determination of the hardness of the sizing of ——. L. Kollmann. Centr. oest.-ung. Papierind.; Papier-Zeit. 1906, **31**, 2714.

FOR the determination of the hardness of the sizing of paper, the author recommends two solutions: (*a*) a 1 per

cent. solution of caustic soda, and (*b*) a solution of 0·5 grm. of phenolphthalein in 10 c.c. of alcohol, 1 c.c of this being then diluted to 40 c.c. by water. A square piece of the paper is pinned across a wooden frame, and a drop of the diluted phenolphthalein solution is placed upon it by means of a glass rod The frame is then turned over, and a drop of the caustic soda solution is placed on the other side of the paper, exactly over the phenolphthalein At the instant of dropping the caustic soda on the paper, a stop-watch is started, and the frame is then again reversed. When the red coloration first appears, the watch is stopped, and the number of seconds which have elapsed gives the absolute resistance of the size The relative resistance is calculated by dividing the absolute value by the weight of the paper in grms. per sq metre. Papers with an absolute resistance below 20 are soft-sized and unsuitable for writing; good writing papers should show an absolute resistance of 30—40 seconds.—J. F. B.

Wood pulp; Reagent for detecting mechanical ——. A. Bergé XXIII., page 912

ENGLISH PATENTS.

Papers [*Mordanted*] *for typewriting, copying, &c* J. Hawke, New Barnet. Eng. Pat. 16,623, Aug. 16, 1905.

IN order to make the press-copies of typewriting and other fugitive inks more permanent, the paper is impregnated with a salt of tin, such as stannous chloride, in the proportion of 1—1·5 parts of tin salt to 1000 parts of paper, in the course of manufacture.—J F B

Paper-making machines [*Control of drying*]. G. Harrison, London. From L. P. Strickland, Brooklyn, U.S.A. Eng. Pat. 17,249, Aug. 25, 1905.

THIS invention relates to a mechanism which is adjusted on the last drying cylinder of the paper machine, in order to regulate the dryness of the web of paper. The attachment consists of a tension roller, which is connected with a reversible transmission mechanism by means of a rock-shaft, levers, pendulum and spur-wheels. When the web is passing away at the correct degree of dryness, the tension roller is adjusted so that the pendulum carrying the spur-wheels is out of gear When the web becomes either too damp or too dry, the pressure on the tension roller is either relaxed or increased, and the pendulum swings either to the right or left, throwing the spur-wheels into gear with a mechanism which supplies either more or less steam to the drying cylinders.—J. F. B.

[*Cardboard, &c.*] *Substances; Rendering* —— *non-conductive, waterproof, and acid-proof.* H. D. Haigh, P. Wheeler, and W. Appleyard, all of Sheffield. Eng. Pat. 1804, Jan 24, 1906.

CARDBOARD, paper, or other suitable porous material, or articles made therefrom, are treated in a closed vessel, under the exhaust action of an air-pump, with a hot solution of 3 parts of asphaltum or bitumen and 1 part of resin.—J. F. B.

Parchment paper; Manufacture of ——. G. Sachsenröder, Barmen-Unterbarmen, Germany. Eng. Pat. 6123, March 13, 1906. Under Int. Conv., June 5, 1905.

SEE Fr. Pat. 362,463 of 1906; this J., 1906, 712.—T. F. B.

UNITED STATES PATENT.

Paper; Grease- and moisture-proof ——. A Weingaertner, Assignor to the National Biscuit Co., Chicago, Ill. U.S Pat. 828,004, Aug. 7, 1906.

THE paper is prepared by soaking it in a solution containing casein, sulphurous acid, ammonia, and a fluoride or free hydrofluoric acid. The impregnated paper is then coated on one side with a film of paraffin.—W. P. S.

FRENCH PATENTS.

Wax substitute to be used in the production of coloured papers; Manufacture of ——. F. M. Winter. Fr. Pat. 364,069, March 13, 1906. XII., page 894.

Celluloid, horn, &c.; Decoration of —— *with metallic deposits of gold, silver, &c.* L. Schwob and G. H. Dilette. Fr. Pat. 364,559. March 24, 1906.

ARTICLES of celluloid or horn are coated with a deposit of silver by a special method (Fr. Pat. 359,001; this J., 1906, 323), then the space on which the design is to appear is covered with a protective varnish, and the excess of silver is removed by means of an acid. The varnish is now removed by a solvent, and the details of the design are executed in *réponssé* work. The portions of the design which are not to be gilded are again covered with varnish, and gold is deposited electrolytically on the exposed surfaces of silver, and the varnish is again removed. If a portion of the silver is to be "oxidised," the remainder is covered with varnish, and the articles are immersed in a bath of ammonium sulphide.—J. F. B.

Celluloid, Manufacture of materials resembling ——. C. Claessen. Fr. Pat. 364,604, March 26, 1906.

IN the manufacture of substances resembling celluloid, either the whole or a part of the camphor usually employed is replaced by compounds belonging to the group of tetra-substituted ureas, in which all the hydrogen atoms of the amino groups are replaced by organic radicals.—J. F B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 867.)

Ergot alkaloids. G. Barger and F. H. Carr. British Association (Section B), York, 1906. Chem. News, 1906, **94**, 89.

AS a result of analyses and molecular weight determinations, the authors give $C_{28}H_{32}O_4N_4$ as the formula for the crystalline ergotinine. No crystalline derivatives could be obtained. It contains no phenolic or methoxy-groups. From the mother-liquors an amorphous alkaloid was obtained in a state of purity, for which the authors suggest the name *ergotoxine*. It forms crystalline salts with oxalic, tartaric, and phosphoric acids, and probably contains a phenolic hydroxyl. The analytical data point to a formula differing but slightly from that of ergotinine Ergotoxine produces, in doses of a few mgrms., all the typical effects of ergot. It is probable that ergotoxine is the one essential active principle, whilst pure crystalline ergotinine is physiologically almost inactive.—F. SHDN.

Columbo root; Alkaloids of ——. E. Günzel. Arch. Pharm., 1906, **244**, 257—269.

THE Columbo root (*Jateorrhiza palmata*) was ground and extracted with alcohol. The alcoholic extract was taken up with water, and shaken out with ether, to remove the columbin The aqueous portion was treated with potassium iodide. The precipitate was boiled with alcohol, leaving behind the iodide of a base, columbamine. From the alcohol there was obtained the iodide of another base, melting at 210° C., and designated as alkaloid "B." From alcohol, columbamine iodide can be crystallised in orange-coloured needles, with a bitter taste and strong tinctorial properties. The iodide melts at 224° C. It contains apparently four methoxyl groups. If the iodide be digested with silver chloride, columbamine chloride is obtained, which crystallises from water in two forms, *viz*, dark brown columns, containing 4 mols. of water, and melting at 184° C., and yellow needles, melting at 194° C. Analyses of air-dried and anhydrous specimens of the chloride point to $C_{21}H_{22}NO_5Cl$ as the formula. An acid sulphate was obtained by treating columbamine iodide with silver sulphate. This crystallises from alcohol in yellow tablets, melting at 220°—222° C. On treating an ammoniacal solution of the iodide with ammonium sulphide, a pentasulphide was formed, melting at 139° C. The iodide when reduced with zinc and sulphuric acid yields tetrahydrocolumbamine, $C_{21}H_{25}NO_5$. This crystallises from methyl alcohol in white transparent leaflets, melting at 142° C. The base contains four methoxyl groups and a free phenolic hydroxyl. The

gold salt melts at 201° C., and the platinum salt at 228° C. Columbamine acid sulphate was reduced electrolytically. (See also Gadamer, this J., 1902, 1294.)—F. Shdn.

Ephedrine and pseudoephedrine. H. Emde. Arch. Pharm., 1906, **244**, 241—255.

By means of crystallographic measurements and determinations of the optical rotation, the author proves the identity of natural pseudoephedrine and that prepared from ephedrine. Ephedrine and pseudoephedrine when treated with methyl iodide give methyl derivatives which are not identical. On prolonged boiling, methylpseudoephedrine methyl hydroxide decomposes into trimethylamine and an alcohol, C_9H_9OH, boiling at 197°- 199° C., and isomeric with cinnamic alcohol. A similar alcohol can be obtained from ephedrine Methylephedrine methyl iodide treated with moist silver oxide yields methylephedrine. The gold salt, $C_{10}H_{14}(CH_3)ON,HCl,AuCl_3$, melted at 126° C., and the platinum double salt, $(B,HCl)_2PtCl_4$, decomposed at 198° C. The alcohol obtained by the decomposition of dimethylephedrine hydroxide boils at 214° C., and appears to be identical with *a*-phenylallyl alcohol, $C_6H_5.CH(OH).CH:CH_2$. The author considers that the difference between ephedrine and pseudoephedrine is due to the hydroxyl grouping being attached to different carbon atoms. The following formula is suggested for ephedrine: $C_6H_5.CH(OH).CH(NH.CH_3).CH_3$ (See this J., 1906, 606.)
—F. Shdn.

Essential oil; Formation and distribution of —— *in a perennial plant.* Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils. 1906, **3**, [2], 5—19. Chem. Centr., 1906, **2**, 533.

The formation and distribution of the essential oil in the wormwood (absinthe) plant, *Artemesia absanthium*, was investigated, the plants being examined at four different stages: (1) in the first year, a considerable time before flowering; (2) at the beginning of flowering; (3) towards the end of flowering; and (4) at the end of the flowering period. The results are set out in tabular form. They show that up to the beginning of the flowering period, there is a vigorous formation of essential oil, but immediately the flowers have fulfilled their function, a considerable quantity of oil is found to have disappeared, being consumed in the process of fertilisation. There is thus a loss of essential oil if the crop be gathered only after the fertilisation of the flowers. Towards the end of the period of growth of the plant, the quantity of oil increases again to some extent, but this is due to the formation of young shoots, and does not affect the loss of essential oil mentioned. In young wormwood shrubs the roots, as a rule, contain no essential oil, and the stems only very little, the main quantity being contained in the leaves. Later, at the beginning of the flowering period, the oil makes its appearance in the root, wherein its quantity then increases up to the end, the loss of oil during the fertilisation of the flowers being borne by the stems, leaves, and flowers.
—A. S.

Terpenic compounds; Gradual distribution of —— *between the different organs of a perennial plant.* Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils, 1906, **3**, [2], 19—35. Chem. Centr., 1906, **2**, 534.

Examination of the essential oil from different organs of the wormwood shrub at different periods of growth (see preceding abstract) gave the following results:—Essential oil is found in the plant a long time before the appearance of the first flowers; this oil contains only traces of thujone, and the oil from the stems is less soluble than that from the leaves. The oil contained in the first blossoms immediately after their appearance is less soluble than the oil from the leaves, but this relation does not hold at a later period. The essential oil from the roots contains the largest proportion of esters, after which follow, in the order given, the oil from the stems, from the blossoms, and from the leaves. No considerable differences with respect to the content of free thujol were observed. Thujone, which is less soluble, is present most abundantly in the oil from the leaves, whilst the oil from the stems contains only traces of it. With the approach of the flowering period, the esters accumulate, chiefly in the roots, whilst simultaneously, a considerable quantity of thujone makes its appearance. At this stage, the total increase in weight of the essential oil is greater than that of the thujol. The consumption of essential oil during the fertilisation of the blossoms proceeds in the flowers themselves. Although the consumption of terpenic compounds during this stage is chiefly at the expense of the thujol, the weight of this easily soluble constituent in the blossoms increases, notwithstanding a slight decrease in the total quantity of oil. It is probable that a relatively easily soluble mixture of terpenic compounds migrates from the leaves to the blossoms, where certain of the compounds are consumed so rapidly during the fertilisation period, that a loss of essential oil takes place, notwithstanding the inflow from the leaves. After the completion of the fertilisation period, fresh quantities of oil are formed in the young shoots, whilst the quantity of oil in the blossoms continually decreases.—A. S.

Essential oils; Contribution to the study of ——. Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils, 1906, **3** [2], 35—40. Chem. Centr., 1906, **2**, 534—535.

Wormwood (Absinthe) oil.—Three specimens of oil were examined, two, distilled respectively in 1900 (I.) and 1905 (II.), from wild wormwood (from the mountains near Caussols, Maritime Alps), and one (III.) from a plant cultivated at Grasse. The figures given in the following table relate to the oil separated directly from the aqueous distillate:—

	I.	II.	III.
	Per cent.	Per cent.	Per cent.
Esters	9·0	5·5	35·6
Combined alcohol	7·0	4·3	27·9
Free alcohol	71·9	76·3	12·3
Thujone	8·4	3·0	7·6

These oils thus contain relatively less thujone but much more thujol than those obtained from America and from the neighbourhood of Paris.

Verbena oil.—The oil from plants of *Verbena triphylla* L., cultivated at Grasse, was examined. The esters and alcohols were determined in a sample of the oil which had been freed from citral by shaking with a dilute solution of sodium sulphite and sodium bicarbonate. The following results were obtained, I. representing the oil from the leaves, and II., that from the blossoms:—

	I			II.
	Decanted oil	Extracted oil.	Total oil.	Total oil.
Yield, per cent. of the fresh plant	—	—	0·195	0·132
$[\alpha]_D$	—18° 20′	—3° 28′	—14° 16′	—8° 24′
Esters, per cent.	3·4	3·6	3·5	3·2
Combined alcohol, per cent.	2·7	2·8	2·8	2·5
Free alcohol, per cent	13·6	24·2	16·5	13·8
Citral, per cent	32·5	43·2	35·4	29·6

The roots yielded 0·014 per cent., and the stems 0·007 per cent. of oil including that obtained by extraction of the aqueous distillate.

Clary oil.—Two specimens of oil extracted from the aqueous distillate obtained from the clary plant, *Salvia sclarea*, L., (from the neighbourhood of Grasse), by distil-

lation with steam, were examined with the following results :—

	1904.	1905
$[\alpha]_D$	−25° 54′	−62° 30′
$[\alpha]_D$ after saponification	−0° 10′	+7° 8′
Sp. gr at 15° C	0·930	0·906
Saponification value	123·2	73·3
Esters, as linalyl acetate, per cent	43·1	25·7
Saponification value after acetylation	147·7	114·7
Free alcohols, as $C_{10}H_{18}O$, per cent	7·6	12·4
Total alcohols, per cent	41·5	32·6

—A. S.

Otto of rose. E. J. Parry. Chem. and Drug., 1906, **69**, 230.

THE author states that adulteration of otto of rose is now practised to a greater extent than at any time since the product has been regularly submitted to chemical analysis. Otto of rose distilled *in vacuo* contains a large amount of phenyl-ethyl alcohol, and is also abnormal in other respects, and this has led to the sale of products, largely adulterated with geraniol and other substances, as otto of rose "distilled by a special process." The author states that pure otto of rose distilled in the normal Bulgarian fashion, never has a specific gravity over 0·855 ; the figure usually falls between the limits, 0·850 and 0·853 at 30° C., and all specimens having high specific gravity, but not containing phenyl-ethyl alcohol, should be rejected.—A. S.

Ether ; Rectification of ——. P. Guigues. J. Pharm. Chim., 1906, **24**, 204.

ETHER containing a small percentage of alcohol may be purified by distilling with about 0·5 per cent. of colophony, which retains the alcohol, so that the last fractions of the distillate maintain a sp. gr. of 0·720. The method affords an economical means of obtaining absolute ether, but is only applicable to a product containing no other impurity than alcohol.—J. O. B.

Acetic anhydride ; Stability of aqueous and alcoholic solutions of ——. A. and L. Lumière and H. Barbier. Bull. Soc. Chim., 1906, **35**, 625–629.

THE authors have previously shown that acetic anhydride can be dissolved in water without hydrolysing completely ; 12 parts of the anhydride dissolve in 100 parts of cold water on merely shaking. Two solutions of acetic anhydride were made up, the strengths being 5 and 10 per cent. respectively. At intervals of 10 minutes 10 c.c. were withdrawn, shaken with aniline, and the free acetic acid titrated. The following table shows some of the results, the figures giving the percentage of acetic anhydride hydrolysed.

Time.	5 per cent		10 per cent	
	15° C	0° C	15° C	0° C
Immediately	9·2	4·6	11·5	9·8
10 mins.	52·5	35·0	58·2	34·6
50 ,,	100·0	76·2	91·7	73·3
100 ,,	—	96·9	100·0	92·8
110 ,,	—	100·0	—	94·8
160 ,,	—	—	—	100·0

Two solutions of acetic anhydride in alcohol were prepared, one equimolecular, the other containing 10 per cent. of the anhydride. 10 c.c. were removed at intervals of a day, and the free acid titrated. It was found necessary to dilute the solution freely with water, before the titration, to secure accurate results. At the end of 30 days, 91·6 per cent. of the acetic anhydride was hydrolysed in the 10 per cent. solution, while in the equimolecular solution, 95·6 per cent. was hydrolysed.—F. SHDN.

Bismuth salts ; Formation of —— by means of bismuth nitrate-mannitol solution. L. Vanino and F. Hartl. J. prakt. Chem., 1906, **74**, 142—152.

MOLECULAR proportions of crystalline bismuth nitrate and mannitol are ground together, and the mass dissolved in water. If acetone be added a hard crystalline substance is produced, having the composition, $C_6H_{14}O_6.2Bi(NO_3)_3$. By a similar reaction, the compound, $C_6H_{14}O_6.Bi(NO_3)_3$, can be obtained from sorbitol and bismuth nitrate. If dulcitol and bismuth nitrate be ground together, the mass does not entirely dissolve in water. On adding acetone, a basic bismuth-dulcitol compound is produced, $C_6H_{14}O_6.BiO.NO_3$. Salts of bismuth can be obtained by mixing together, in solution, molecular proportions of the bismuth mannitol compound and the required acid or its sodium salt. The following were prepared. Bismuth salicylate, $Bi(C_6H_4OH\,COO)_3.2H_2O$. Bismuth camphorate, $Bi_2[C_8H_{14}(COO)_2]_3.C_8H_{14}(COOH)_2$. Bismuth phthalate, $Bi[C_6H_4(COOH)(COO)]_3$. Bismuth citrate, $BiC_6H_5O_7$. Bismuth benzoate $Bi(C_6H_5COO)_3$. Bismuth oxalate, $Bi_2(C_2O_4)_3.H_2O$. Bismuth nitrite, $BiO.NO_2.\frac{1}{2}H_2O$. Bismuth hypophosphite $Bi(H_2PO_2)_3$. Bismuth phosphite $Bi_2(HPO_3)_3.3H_2O$. Bismuth phosphate, $BiPO_4.3H_2O$. Bismuth borate, $BiBO_3.2H_2O$. Bismuth ferrocyanide, $Bi_4[Fe(CN)_6]_3.2K_4Fe(CN)_6$.—F. SHDN.

Thebaine ; Reactions of ——. C. Reichard. XXIII, page 912.

ENGLISH PATENTS.

Seaweed ; Manufacture of products from ——. The British Algin Co. and T. Ingham, Holywell, Flint. Eng. Pat. 25,187, Dec. 5, 1905.

CLAIM is made for a method of preparing soluble double salts of alginic acid, sufficiently pure for technical purposes, by neutralising the extract from the seaweed, and adding a soluble salt of a metal (*e.g.* zinc, aluminium, iron, cadmium, copper, &c.), the alginate of which is insoluble in sufficient quantity to precipitate the whole of the alginic acid, separating the insoluble compound, and dissolving it in a solution of an alkali hydroxide or carbonate. Or, a solution of a soluble alginate (*e.g.* of potassium, sodium, ammonium, or magnesium) may be treated with a soluble salt of zinc, aluminium, &c., and caustic alkali or alkali carbonate added to bring the precipitated mass into solution.—C. A. M.

Formates ; Process for the production of ——. Nitritfabrik G.m.b.H., Copenick, Germany. Eng. Pat. 9008, April 14, 1906. Under Int. Conv., April 15, 1905.

IN order to facilitate the commencement of the action of carbon monoxide on alkali or alkaline-earth hydroxides, a small quantity of water is added, or of some substance which will generate water and heat when added to the hydroxide (*e.g.* formic acid). Twelve to 15 kilos. of water are added to 1000 kilos. of sodium hydroxide contained in a digester, and carbon monoxide is introduced into the mass either during, or directly after the addition of the water ; the carbon monoxide is preferably heated, but care is necessary that the temperature of the mass does not rise to the point at which sodium formate decomposes, *i.e.*, it should not rise much above 200° C.—T. F. B.

Oxyquinoline salts ; Process for the manufacture of neutral ——. F. F. Fritzsche and L. Ostermann, Hamburg, Germany. Eng. Pat. 11,725, May 19, 1906. Under Int. Conv., June 2, 1905.

NEUTRAL salts of *o*-hydroxyquinoline may be obtained by mixing solutions of the quinoline derivative and the acid in molecular proportions, and in presence of only such quantity of the solvent (water, alcohol, or ether) that the salt is precipitated directly, without evaporation. For example, the neutral sulphate is prepared by mixing together 10·6 parts of sulphuric acid (65·5° B.), 29 parts of *o*-hydroxyquinoline and 100 parts of 96 per cent. alcohol, and allowing to stand until the salt has separated out ; the sulphate thus obtained is a yellow, crystalline powder, of m.pt. 177·5° C. The phosphate and salts of organic acids are obtained similarly.—T. F. B.

gold salt melts at 201° C., and the platinum salt at 228° C. Columbamine acid sulphate was reduced electrolytically. (See also Gadamer, this J., 1902, 1294.)—F. Shdn.

Ephedrine and pseudoephedrine. H. Emde. Arch. Pharm., 1906, **244**, 241—255.

By means of crystallographic measurements and determinations of the optical rotation, the author proves the identity of natural pseudoephedrine and that prepared from ephedrine. Ephedrine and pseudoephedrine when treated with methyl iodide give methyl derivatives which are not identical. On prolonged boiling, methylpseudoephedrine methyl hydroxide decomposes into trimethylamine and an alcohol, C_9H_9OH, boiling at 197°- 199° C., and isomeric with cinnamic alcohol. A similar alcohol can be obtained from ephedrine Methylephedrine methyl iodide treated with moist silver oxide yields methylephedrine. The gold salt, $C_{10}H_{14}(CH_3)ON,HCl,AuCl_3$, melted at 126° C., and the platinum double salt, $(B,HCl)_2PtCl_4$, decomposed at 198° C. The alcohol obtained by the decomposition of dimethylephedrine hydroxide boils at 214° C., and appears to be identical with *a*-phenylallyl alcohol, $C_6H_5.CH(OH).CH:CH_2$. The author considers that the difference between ephedrine and pseudoephedrine is due to the hydroxyl grouping being attached to different carbon atoms. The following formula is suggested for ephedrine: $C_6H_5.CH(OH).CH(NH.CH_3).CH_3$ (See this J., 1906, 606.)
—F. Shdn.

Essential oil; Formation and distribution of —— *in a perennial plant.* Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils. 1906, **3**, [2], 5—19. Chem. Centr., 1906, **2**, 533.

The formation and distribution of the essential oil in the wormwood (absinthe) plant, *Artemesia absanthium*, was investigated, the plants being examined at four different stages: (1) in the first year, a considerable time before flowering; (2) at the beginning of flowering; (3) towards the end of flowering; and (4) at the end of the flowering period. The results are set out in tabular form. They show that up to the beginning of the flowering period, there is a vigorous formation of essential oil, but immediately the flowers have fulfilled their function, a considerable quantity of oil is found to have disappeared, being consumed in the process of fertilisation. There is thus a loss of essential oil if the crop be gathered only after the fertilisation of the flowers. Towards the end of the period of growth of the plant, the quantity of oil increases again to some extent, but this is due to the formation of young shoots, and does not affect the loss of essential oil mentioned. In young wormwood shrubs the roots, as a rule, contain no essential oil, and the stems only very little, the main quantity being contained in the leaves. Later, at the beginning of the flowering period, the oil makes its appearance in the root, wherein its quantity then increases up to the end, the loss of oil during the fertilisation of the flowers being borne by the stems, leaves, and flowers.

Terpenic compounds; Gradual distribution of —— *between the different organs of a perennial plant.* Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils, 1906, **3**, [2], 19—35. Chem. Centr., 1906, **2**, 534.

Examination of the essential oil from different organs of the wormwood shrub at different periods of growth (see preceding abstract) gave the following results:—Essential oil is found in the plant a long time before the appearance of the first flowers; this oil contains only traces of thujone, and the oil from the stems is less soluble than that from the leaves. The oil contained in the first blossoms immediately after their appearance is less soluble than the oil from the leaves, but this relation does not hold at a later period. The essential oil from the roots contains the largest proportion of esters, after which follow, in the order given, the oil from the stems, from the blossoms, and from the leaves. No considerable differences with respect to the content of free thujol were observed. Thujone, which is less soluble, is present most abundantly in the oil from the leaves, whilst the oil from the stems contains only traces of it. With the approach of the flowering period, the esters accumulate, chiefly in the roots, whilst simultaneously, a considerable quantity of thujone makes its appearance. At this stage, the total increase in weight of the essential oil is greater than that of the thujol. The consumption of essential oil during the fertilisation of the blossoms proceeds in the flowers themselves. Although the consumption of terpenic compounds during this stage is chiefly at the expense of the thujol, the weight of this easily soluble constituent in the blossoms increases, notwithstanding a slight decrease in the total quantity of oil. It is probable that a relatively easily soluble mixture of terpenic compounds migrates from the leaves to the blossoms, where certain of the compounds are consumed so rapidly during the fertilisation period, that a loss of essential oil takes place, notwithstanding the inflow from the leaves. After the completion of the fertilisation period, fresh quantities of oil are formed in the young shoots, whilst the quantity of oil in the blossoms continually decreases.—A. S.

Essential oils; Contribution to the study of ——. Roure-Bertrand, fils. Wiss. u. ind. Ber. von Roure-Bertrand, fils, 1906, **3** [2], 35—40. Chem. Centr., 1906, **2**, 534—535.

Wormwood (Absinthe) oil.—Three specimens of oil were examined, two, distilled respectively in 1900 (I.) and 1905 (II.), from wild wormwood (from the mountains near Caussols, Maritime Alps), and one (III.) from a plant cultivated at Grasse. The figures given in the following table relate to the oil separated directly from the aqueous distillate:—

	I.	II.	III.
	Per cent.	Per cent.	Per cent.
Esters	9·0	5·5	35·6
Combined alcohol	7·0	4·3	27·9
Free alcohol	71·9	76·3	12·3
Thujone	8·4	3·0	7·6

These oils thus contain relatively less thujone but much more thujol than those obtained from America and from the neighbourhood of Paris.

Verbena oil.—The oil from plants of *Verbena triphylla* L., cultivated at Grasse, was examined. The esters and alcohols were determined in a sample of the oil which had been freed from citral by shaking with a dilute solution of sodium sulphite and sodium bicarbonate. The following results were obtained, I. representing the oil from the leaves, and II., that from the blossoms:—

	I			II.
	Decanted oil	Extracted oil.	Total oil.	Total oil.
Yield, per cent. of the fresh plant	—	—	0·195	0·132
$[\alpha]_D$	—18° 20′	—3° 28′	—14° 16′	—8° 24′
Esters, per cent.	3·4	3·6	3·5	3·2
Combined alcohol, per cent.	2·7	2·8	2·8	2·5
Free alcohol, per cent	13·6	24·2	16·5	13·8
Citral, per cent	32·5	43·2	35·4	29·6

The roots yielded 0·014 per cent., and the stems 0·007 per cent. of oil including that obtained by extraction of the aqueous distillate.

Clary oil.—Two specimens of oil extracted from the aqueous distillate obtained from the clary plant, *Salvia sclarea*, L., (from the neighbourhood of Grasse), by distil-

formula $R_1R_2C(OH)CH_2X$, where X is a halogen atom; the amino-alcohols are of value in that their benzoyl derivatives possess local anæsthetic properties; the process of preparation above given is stated to be impossible technically, owing to the difficulty of preparing the necessary halohydrins.—T. F. B.

Aminoalkyl esters, Process for preparing ——. J. D. Riedel, Akt.-Ges. Ger. Pat. 169,787, Oct. 8, 1903.

By acidylation of the amino-alcohols described in Ger. Pats. 169,746 and 169,819, containing a tertiary amino-group, aminoalkyl esters of the composition $R_1R_2C(OR).CH_2.NR_3R_4$ are obtained, R being an acidyl group, R_1 and R_2 aryl or alkyl, and R_3 and R_4 alkyl radicals; all these esters are stated to possess the property of producing powerful and permanent anæsthesia; their salts are soluble in water. It thus appears that the acidyl derivatives of the majority of amino-alcohols produce anæsthesia, not excepting those which do not contain the piperidine nucleus. This property is possessed in the highest degree by the esters in which the alcohol group is a tertiary one and the amino-group is in close proximity to the alcohol group.—T. F. B.

Amino-alcohols, Process for preparing ——. J. D. Riedel, Akt.-Ges. Ger. Pat. 169,819, Oct. 8, 1903.

Amino-alcohols of the same composition as that given in Ger. Pat. 169,746 (above), save that R_4 is an alkyl radical, are obtained by the action of organomagnesium halides on aminoacetone or the esters of amino-acids containing a tertiary amino-group; the process is stated to give practically theoretical yields. The following is an example of the various stages of the reaction:—$CH_3MgI + CH_3.CO.CH_2.N(CH_3)_2 = (CH_3)_2C(OMgI)CH_2.N(CH_3)_2$: on adding water, this is decomposed into $MgI(OH)$ and $(CH_3)_2C(OH).CH_2.N(CH_3)_2$.—T. F. B.

Suprarenal glands; Process for preparing stable solutions of the active principle of ——. W. Straub. Ger. Pat. 169,446, May 25, 1904.

The only known method of preparing stable solutions of the active principle of the suprarenal gland has been by the use of its hydrochloride in presence of free hydrochloric acid; it is now found that stable solutions can also be obtained by the use of aldehyde- or ketone-alkali bisulphite compounds, with or without addition of cocaïne.—T. F. B.

Diethylacetyldiethylamide; Process for preparing ——. Kalle und Co. Ger. Pat. 168,451, Aug. 19, 1904.

Diethylacetyldiethylamide is obtained by the action of diethylacetyl chloride on diethylamine; it is of medicinal value, among its properties being that of raising the temperature of the blood, a property not possessed by diethylacetylmonoethylamide.—T. F. B.

1-Ethyl-3.7-dimethylxanthine and the alkali salts of benzoic acid or salicylic acid; Process for preparing easily soluble double salts from ——. J. D. Riedel, Akt.-Ges. Ger. Pat. 170,302, Sept. 29, 1904

Aqueous solutions of equimolecular parts of 1-ethyl-3.7-dimethylxanthine and an alkali salt of benzoic acid or salicylic acid are mixed together, and the double salt which forms is isolated, either by evaporation to dryness, or by precipitation from its aqueous solution with alcohol or acetone. The products are stated to be easily soluble in water, and without the bitter taste possessed by the corresponding salts from 1.3.7-trimethylxanthine.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 867.)

Silicic acid emulsions; Experiments with ——. K. Schaum and E. Schloemann. Z. wissen. Phot.; Brit. J. Phot., 1906, **53**, 687—688.

A silicic acid emulsion was prepared by adding a solution of silicic acid (purified by dialysis) containing potassium bromide to a solution of silicic acid containing silver nitrate, filtering off the coarse-grained silver bromide, and coating on plates; the dried films were found to separate partially from the glass, so wet films were employed for the experiments; the speed of the emulsion was found to be very much smaller than that of a "transparency" plate, as measured in a tube sensitometer. Solarisation was very marked on over-exposed films, thus showing that it is not due to "tanning" of the vehicle of the emulsion, but to some modification of the silver salt. Further, it was found that the plates, fixed immediately after exposure, could be afterwards developed; secondary development was also found to take place after the fixed plates had been treated with nitric acid (sp. gr. 1·3) for one hour, the density being less in the plates treated with acid. The portion of the latent image stable to thiosulphate and nitric acid has frequently been ascribed to an organic compound, but from the above experiments it appears that Eder's view is the correct one, *viz.*, that the latent image consists partly of a silver subbromide stable to thiosulphate and to nitric acid.—T. F. B.

Emulsion of silver erythrosinate, A panchromatic ——. C. E. K. Mees and S. H. Wratten. Phot. J., 1906, **46**, 300.

An emulsion containing silver erythrosinate in place of a silver halide was prepared by slowly adding silver nitrate solution to a mixture of gelatin and excess of erythrosin, and subsequently digesting for 40 minutes at 150° F.; after further addition of gelatin, the mixture is allowed to set and washed, and digested again for 30 minutes. It proved to be exceedingly slow, but gave a strong black image with ordinary alkaline developers, without fogging. It also proved to be almost panchromatic, giving approximately equal densities on exposure behind the three-colour screens.—T. F. B.

French Patent.

Reducing agent for photographic negatives; Product constituting a ——, *and method of using it.* H. E. Smith. Fr. Pat. 364,531, March 24, 1906. Under Int. Conv., March 24, 1905.

See Eng. Pat. 6276 of 1905; this J., 1905, 751.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

English Patents.

Explosives; Impts. in ——. C. E. Bichel, Hamburg. Eng. Pat. 5259, March 3, 1906.

To increase the power of resistance of explosives to shock and disintegration, they are covered with elastic fabric of the stockinette kind, and coated over with lac, varnish, or the like.—C. S.

United States Patent.

Explosive. L. Barthélemy, Paris. U.S. Pat. 829,362, Aug. 21, 1906.

See Fr. Pat. 351,289 of 1905; this J., 1905, 858.—T. F. B.

FRENCH PATENTS.

Cellulose; Nitration of —— by acids concentrated by electricity. G. C. de Briailles. Fr. Pat. 364,349, Jan. 25, 1906.

THE mixture of sulphuric and nitric acids used for the nitration of cellulose becomes diluted by the water separated from the cellulose as a result of the nitration. This water is eliminated from the acids by electrolysis, under an electrical pressure of 3—4 volts. The electrodes are made of platinum or gilded-platinum wire, and the evolution of the hydrogen is assisted by the application of a vacuum. An apparatus is described, in which the nitration of the cellulose and the decomposition of the water can be effected in the same vessel, the latter being divided by a perforated plate into two chambers, the upper chamber containing the cellulose and the lower chamber the acids in the course of concentration. The gases are collected separately for use.—J. F. B

Chlorate explosive for mines. S. Laszczynski. Fr. Pat. 363,919, Feb. 5, 1906

CLAIM is made for an explosive consisting of petroleum (kerosene) with the theoretical quantity of sodium or potassium chlorate. The mixture requires 0·5 grm. of fulminate to cause detonation, and when exploded in a Trauzl lead cylinder it gives an expansion equal to two-thirds that of dynamite containing 75 per cent. of nitroglycerin.—B. J. S.

Explosive; Flameless ——, for guns; C. Duttenhofer. Fr. Pat. 364,413, March 19, 1906.

INDIFFERENT bodies such as vaseline and camphor when introduced into propellants, cause a lowering of the temperature of explosion, and hence prevent the formation of a flame. With explosives having a very high temperature of explosion, such as nitroglycerin and nitrocellulose, the quantity of vaseline required would be so large as to interfere with the ballistics of the powder. In this case, it is found advisable to introduce in addition a small quantity of an alkali carbonate, 1—2 per cent., with 5 per cent. of vaseline. The resulting powder has, it is stated, improved keeping qualities.—B. J. S.

Explosive, and apparatus for its practical use. W. Venier. Fr. Pat. 364,461, March 21, 1906.

A NEW detonator, prepared by passing acetylene or ethylene through an ammoniacal solution of mercury nitrate, is claimed for use in cap compositions. It is used in admixture with potassium chlorate and sulphur, or with aluminium, mercury fulminate, and potassium chlorate, owing to the fact that when used alone, the explosion is very local in character. Detailed drawings are given of the arrangements most suitable for the practical application of this explosive in caps.—B. J. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 870.)

APPARATUS, &c.

UNITED STATES PATENT.

Crucibles; Method of protecting ——. R. A. McDonald, Pittsburg, Pa. U.S. Pat. 828,954, Aug. 21, 1906.

ORDINARY plumbago or carbon crucibles are protected by applying a film or coating of clay or other non-carbonaceous material to their inner surfaces.—W. H. C.

INORGANIC—QUANTITATIVE.

Silver; The galvanometer as indicator in the volumetric determination of ——. M. Drapier. Bull. Soc. Chim. Belg., 1906, **20**, 148—149.

THE E.M.F. of a cell (lead—silver nitrate solution—silver) rises as the concentration of the silver salt decreases by the addition of hydrobromic acid, and a well-marked maximum is reached at the moment of complete precipitation. This indication of the end of the reaction is much sharper and easier to observe than the exact moment when another drop of precipitant fails to produce further turbidity. The silver electrode should be electrolytically coated with silver deposited from a cyanide solution.—J. T. D.

Zinc; Titration of ——, by the Schaffner process. Influence of ammonia and ammonium salts. A. Deckers. Bull. Soc. Chim. Belg., 1906, **20**, 164—167.

AMMONIUM salts in neutral or ammoniacal solution decompose sodium sulphide with evolution of hydrogen sulphide. They react similarly on freshly precipitated zinc sulphide, the intensity of the reaction increasing with the concentration of free ammonia. In the titration of zinc by sodium sulphide, therefore, not only must the assay and the known zinc solution contain equal amounts of ammonia and ammonium salts, but the amount of the latter must not be too considerable.—J. T. D.

Manganese; Determination of small quantities of ——, and a new method of formation of glycerose. N. Tarugi. Gaz. Chim. Ital., 1906, **36** [1], 332—347.

A COLORIMETRIC method for the determination of manganese may be based on the fact that manganous hydroxide is soluble in glycerol, and that the solution is oxidised by the air, or more rapidly by oxygen or sodium hypochlorite, with formation of a red coloration, the intensity of which depends upon the amount of manganese present. Five c.c. of a 1·1 per 1000 solution of manganese are treated with 3 c.c. of glycerol and 1 c.c. of a 50 per cent. solution of sodium hydroxide, and then a slow current of oxygen is passed through for 10 minutes, or 10 c.c. of a solution of sodium hypochlorite containing 3 per cent. of available chlorine are added. The colour is matched by means of standards prepared in a similar manner from a 3·16 per cent. solution of potassium permanganate. Iron and nickel have no influence on the reaction, and cobalt and copper interfere only when the concentration of the manganese is less than 1 per 1000. If sodium hypochlorite be used, it must not be too rich in available chlorine, otherwise the smallest traces of cobalt will interfere with the test.

The author has also observed that glycerol is converted into glycerose by sodium hypochlorite in presence of a drop of a 1 per 1000 solution of a cobalt salt. This is stated to be due not to a catalytic action of the cobalt salt, but to the formation of an unstable peroxide-like compound of cobalt as an intermediate product, recognised by the transient blue coloration produced. A similar formation of a peroxidised compound occurs even in absence of sodium hypochlorite with solutions of cobalt salts of over 2 per cent. strength; in presence of such solutions the red coloration of manganese salts with glycerol, caustic soda, and oxygen is not produced. The presence of copper salts in quantities of less than 1 per 1000 has no influence on the manganese reaction. If chromium, copper, and cobalt be present, however, it is best to heat the solution with ammonia and ammonium persulphate, when these metals remain in solution; the manganese precipitate can be filtered off, washed, dissolved in hydrochloric acid, and examined as described above.—A. S.

Oxidising substances [Potassium permanganate, potassium bichromate]; Determination of —— by means of hydrazine sulphate. L. Medri. Gaz. Chim. Ital., 1906, **36** [1], 373—378.

THE author is unable to confirm the statement of Roberto and Roncali (this J., 1904, 911), according to which 5 mols. of nitrogen are liberated for every 4 mols. of potassium permanganate, when the latter is heated with hydrazine sulphate (see also Petersen, this J., 1895, 772). Experiments in which 5 per cent. and 16·14 per 1000 solutions of permanganate were added to excess of 3 per cent. hydrazine sulphate solution in presence of 10 and of 50 per cent. sulphuric acid, gave the following results:—By the action of potassium permanganate solution on hydrazine sulphate solution acidified with sulphuric acid, the hydrazine is not completely oxidised; nitrogen is evolved in accordance with the equation: $17N_2H_4,H_2SO_4+13O=13H_2O+7(NH_4)_2SO_4+10N_2+10H_2SO_4$. The amount of sulphuric acid may be varied within wide limits, without

affecting the results. In absence of free sulphuric acid, the oxidation of the hydrazine sulphate proceeds further, but not to the extent stated by Roberto and Roncali (*loc. cit.*). The author states that hydrazine cannot be determined by means of permanganate, nor *vice versa*. Potassium bichromate, on the other hand, oxidises hydrazine completely (see Purgotti, Gaz. Chim. Ital., **26** [2], 559).—A. S.

Hydrogen peroxide and ferrous salts and other reducing agents [Sodium nitrite] ; Determination of ——. W. E. Mathewson and J. W. Calvin. Amer. Chem. J., 1906, **36**, 113—116.

THE solution of hydrogen peroxide is diluted with a known amount of water, so that its strength is reduced to about 0·2 *N* (0·3 per cent.). About 2 grms. of ferrous ammonium sulphate are weighed out, dissolved in a little water, and a few grms. of ammonium sulphate and some phosphoric acid added. A solution of titanium potassium sulphate, prepared by fusing the dioxide with potassium hydrogen sulphate, dissolving in cold dilute sulphuric acid, and filtering, is then added as indicator, and the mixture titrated with the hydrogen peroxide solution. The appearance of the deep yellow titanium trioxide marks the completion of the reaction.

The method may be employed for the determination of sodium nitrite, using a solution of hydrogen peroxide already standardised by this salt. To prevent loss of nitrous acid the approximate quantity of hydrogen peroxide, ascertained by a rough preliminary titration, should be added before the indicator.—F. SODN.

Phosphoric acid ; Causes of error in determining —— in natural phosphates and basic slags by the "citro-mechanical" method. E. Guerry and E. Toussaint. Bull. Soc. Chim. Belg., 1906, **20**, 167—198.

THE citric acid method is always liable to error through the co-precipitation of silica where it is present, and in all accurate analyses the silica should be first removed. The authors find, however, that the presence of ferric salts greatly retards the precipitation of silica, and for technical purposes the following method gives sufficiently accurate results :—2·5 grms. of the substance are mixed with 100 c.c. of water, 30 c.c. of nitro-hydrochloric acid are added, the liquid is boiled for half an hour, cooled, and made up to 250 c.c. To 25 c.c. of this solution are added 25 c.c. of solution of ferric chloride (4 grms. per litre), 50 c.c. of water, 30 c.c. of ammonium citrate solution (containing 10 grms. of citric acid), and 15 c.c. of ammonia (0·910). This is mechanically agitated for half an hour, whilst 50 c.c. of magnesia mixture are added drop by drop The precipitate is allowed to settle for an hour, filtered off, the beaker rinsed with water containing 10 per cent. of ammonia and 10 per cent. of the citrate solution, and the precipitate washed once with this liquid and afterwards with dilute ammonia as usual.

As a general method of decomposition, the use of sulphuric acid is recommended, which expels hydrofluoric acid, and renders the silica insoluble. The substance (2·5 grms.) is heated in a Jena flask or a platinum basin with 10 c.c. of concentrated sulphuric acid, shaking or stirring from time to time, till white fumes are evolved. After cooling, water is cautiously added to make the volume 100 c.c., then 25 c.c. of nitro-hydrochloric acid, the liquid boiled for 10 minutes, cooled, made up to 250 c.c., and filtered through a dry filter. Of this solution 25 c.c. are taken, 5—10 c.c. of the ferric chloride solution are added, the liquid nearly neutralised by ammonia, 30 c.c. of citrate solution and 15 c.c. of ammonia added, and the phosphate precipitated by 25 c.c. of magnesia mixture added during half an hour while mechanical agitation goes on.—J. T. D.

ORGANIC—QUALITATIVE.

Tanning matters ; Qualitative analysis of ——. M. Nierenstein. Chem.-Zeit., 1906, **30**, 868.

NOT only quebracho tannin, as previously reported (see page 898), but all pyrocatechol tanning matters yield a precipitate with diazobenzene chloride, whereas no pyrogallol-tannin gives the reaction. The reaction is carried out by adding to the cold solution of the tanning material, drop by drop, a ½-per cent. solution of diazobenzene chloride. The precipitate appears at once. The solution of the reagent may be kept unchanged for months in a brown glass bottle.—A. G. L.

Wood pulp ; Reagent for detecting mechanical ——. A. Bergé. Bull. Soc. Chim. Belg., 1906, **20**, 158—159.

THE author recommends the following reagent for the detection of mechanical wood pulp [lignocellulose] : *p*-nitraniline 0·2 grm. ; sulphuric acid at 66° B., 20 grms. ; water, 80 grms. Paper containing mechanical wood-cellulose is coloured orange with a brick-red shade. The coloration is easily recognised in the single fibres under the microscope, and the reagent gives no coloration with unbleached chemical pulp unless the boiling has been deficient. The solution will keep indefinitely.—J. F. B.

Thebaïne ; Reactions of ——. C. Reichard. Chem.-Zeit., 1906, **30**, Rep. 287 ; from Pharm. Zentral-H., 1906, **47**, 623.

ON rubbing together a few crystals of thebaïne and mercurous nitrate in a glazed porcelain mortar, and adding a few drops of water to the mixture, the latter assumes a blackish colour after half an hour or an hour. This reaction serves to distinguish thebaïne from narcotine, narceïne, and papaverine, or to detect thebaïne in a mixture of these bases.

Thebaïne may be distinguished from codeïne by means of its reaction with diphenylamine and sulphuric acid. On mixing a little diphenylamine with a few crystals of thebaïne on a porcelain tile, and adding a drop of cold concentrated sulphuric acid, the mixture immediately assumes a deep reddish-brown coloration, which slowly changes partly into green ; after the mixture has remained for 12 hours in the air, the colour changes to an intense violet-blue.—T. H. P.

ORGANIC—QUANTITATIVE.

Tannin analysis ; Use of chromed hide powder in ——. E. Nihoul. Bull. Soc. Chim. Belg., 1906, **20**, 236—240.

THE author has compared, using the I.A.L.T.C. method, samples of chromed hide powder with an old hide powder which had been kept for a year. He finds that from chromed powder containing 1 per cent. and 5 per cent. of chromic oxide respectively, distilled water only extracts about 2 mgrms. of soluble matter, as compared with 21 mgrms. from the old hide powder, in the 50 c.c. of the filtrate used for the determination of the non-tannins. Working with a standard solution of quebracho extract and 5·5 grms. of powder, almost exact results were obtained with the lightly chromed powder ; those from the hide powder as well as those from the heavily chromed preparation, were incorrect. With a larger weight (13 grms.) of the heavily chromed powder, good results were obtained ; but since good results are also obtained by the use of 5·5 grms. of lightly chromed powder, the author favours the adoption of the latter, providing it contain enough chromic oxide to keep well.—S. R. T.

Leather ; Determination of sulphuric acid in ——. L. Meunier. Collegium, 1906, 296—300.

THE following modification of the method of Nihoul and de Koninck (Monit. Scient., 1904, 504) gives good results. A hard glass tube about 50 cm. in length is bent, and drawn out at one end. A plug of glass wool is placed near the bend, next about 20 cm. of pure granulated calcium nitrate (prepared according to directions given by Nihoul and de Koninck), and then a mixture of small fragments of the leather and calcium nitrate. A current of oxygen is led through the open end of the tube, the bent delivery tube dipping beneath the surface of an alkaline solution. The portion of the tube containing calcium nitrate is now carefully heated, and subsequently the heating is extended to that portion containing the leather and nitrate. The leather burns easily in the presence of oxygen, and any volatile products escaping primary

combustion are burnt up by the calcium nitrate; the sulphuric acid formed is retained by the lime. When combustion is complete, the receiver containing the alkali is removed, and its contents evaporated to dryness in a platinum dish, incinerated over a spirit lamp, the residue dissolved in hydrochloric acid, and tested for sulphates. If the experiment has been properly carried out, these should be absent. When cool, the contents of the combustion tube are transferred to a beaker with water, and nitric acid neutralised if present. Hydrochloric acid is then added, and sulphuric acid is determined in the usual way. The process is accurate, but somewhat long and difficult on account of the large quantity of saline matter in the solution.

In the following method, these difficulties are obviated. The leather is burnt in oxygen in a Mahler's bomb calorimeter under a pressure of 30 atmospheres. Four pieces of about 20 mm. diameter and 2 grms. in weight, are punched out from different portions of the leather. A similar section is taken from each as an average sample for combustion, the remainder being used for the determination of moisture and normal sulphates, the latter by direct incineration without alkali. The sample for combustion is moistened with a 3 per cent. solution of potassium carbonate, and dried. Fifty c.c. of $N/10$ sodium carbonate solution are introduced into the bomb, and the sample is then placed in the platinum capsule and the bomb closed. The combustion is carried out in the usual way. After completion, the contents of the bomb and capsule are washed out and mixed, and, if necessary, filtered. When combustion has been complete, the filtrate will be colourless. It is acidified with hydrochloric acid, and evaporated to dryness in a porcelain dish. The residue is moistened with strong hydrochloric acid, and re-dried once or twice to expel nitric acid formed during the combustion. It is then dissolved in dilute acid, and the sulphuric acid precipitated as barium sulphate.

If A be the percentage of sulphuric anhydride calculated on the dry leather, B the percentage present in the ash as normal sulphate, and C the percentage corresponding to the average sulphuric acid content of the skin substance of leather, then $X = A - (B - C)$, where X is the percentage of sulphuric anhydride corresponding to the free acid of the leather. C must be experimentally determined once for all.—S. R. T.

Volatile fatty acids; Determination of soluble and insoluble —— [in butter]. J. Delaite and J. Legrand. Bull. Soc. Chim. Belg., 1906, **20**, 230—235.

To obtain concordant results in the determination of the Reichert-Meissl value, all the details of the process must be standardised; variations in any of the conditions lead to variations in the results. Especially the duration of saponification greatly influences the results; the longer the period the higher the Reichert-Meissl value obtained. The authors think this is due to de-polymerisation of the acids. Saponification by glycerol yields a lower value than saponification by alcohol, probably because at the higher temperature some of the acids are completely decomposed. The figure for insoluble acids, on the other hand, is always higher with glycerol than with alcohol; and the authors consider that in saponifying with glycerol, in using the Polenske process for cocoanut oil, there is always a liability to error.—J. T. D.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 871.)

Coagulation; Nature of ——. N. Pappadà. Gaz. Chim. Ital., 1906, **36** [2], 259—264.

The author's experiments on the coagulation, in dilute solution, of colloidal silicic acid, Prussian blue, copper ferrocyanide, and colloidal silver gave the following results: (1) Solutions of non-dissociated organic compounds have no coagulating action. (2) The coagulating action of electrolytes with monovalent cathions depends on the velocity of hydro-diffusion of the latter, and increases as this velocity increases. The following series gives the cathions arranged according to the decreasing magnitude of their coagulating actions: hydrogen, cæsium, rubidium, potassium, ammonium, sodium, lithium; the hydrogen ion is an exception as regards its action on silicic acid. (3) For electrolytes with bivalent cathions, the coagulating action varies in the same way in the same group of elements, but is greater than that of electrolytes with univalent cathions; and (4) the same holds for electrolytes with tervalent cathions.

The coagulating action of electrolytes depends also on the electric charge of the cathion, and, with solutions of chemically equivalent concentrations, increases with this charge.—T. H. P.

Desamido-casein. Z. H. Skraup and P. Hoernes. Monatsh. Chem., 1906, **27**, 631—652.

Nitrous acid reacts with albumins with evolution of nitrogen. According to Schiff, this nitrogen is derived from amido groups, $CONH_2$, whereas Paal has suggested that it is derived from the decomposition of free amino groups which are not coupled up in the form of peptide compounds. The authors have investigated the case of casein, and have obtained desamido-casein, a yellow body, as the product of the action of nitrous acid. In order to throw light on the above constitutional question they have made a complete study of the products of hydrolysis of desamido-casein. For instance, if any amino groups were present in casein in the free form, they should have been replaced by hydroxyl groups by the action of nitrous acid, and the residues containing them should appear amongst the products of hydrolysis in the form of hydroxy-acids. The authors, however, could detect no hydroxy-acids amongst these products. Desamidocasein on hydrolysis yields products very similar to those obtained from casein, with the exception that the tyrosine and the lysine which are obtained from casein are absent in the case of desamido-casein.—J. F. B.

Desamido-glutin. Z. H. Skraup. Monatsh. Chem., 1906, **27**, 653—662.

A study with gelatin on exactly similar lines to that on casein (see above), and leading to similar results, particularly as regards the absence of lysine from the products of hydrolysis.—J. F. B.

Casein; Some peptones obtained from ——. Z. H. Skraup and R. Witt. Monatsh. Chem., 1906, **27**, 663—684.—J. F. B.

Trade Report.

Italy; Tariff Modifications in ——.

Bd. of Trade J., Aug. 30 *and Sept.* 6, 1906.

The following are additions to the list of import duties given on page 871 of the Journal for Sept. 15:—

Tariff No.	Article.	Rate of duty. Per 100 kilos. Former.	Present.
		Lire cts.	Lire cts.
231	Arsenic, metallic	1 00	7 50
234	*Aluminium and its alloys with copper:—*		
	(a) Crude	5 00	80 00
	(b) Sheets, rods, and tubes	10 00	50 00
	(c) Wire	10 00	50—75 Lire
	(d) Manufactured	120 00	150 00
280	*Natural umber*	4 00	Free
307	Palm oil	4 00	Free
	Cocoanut oil	15 00	4 00 / 20 00
338 bis	*Paraffin candles**		
354 bis	*Celluloid:—*		
	(a) Rough, in lumps, or sheets or leaves not polished or otherwise worked	As fine cardboard	Free
	(b) Sheets, leaves, &c., polished, or subjected to other surface treatment		15 00

* Candles of stearine mixed with paraffin in a proportion exceeding 30 per cent are regarded as paraffin candles.

Additions to the tariff are printed in *italics*.

New Books.

THE CLAYWORKER'S HANDBOOK. A Manual for all engaged in the Manufacture of Articles from Clay. By the Author of "The Chemistry of Clayworking," &c. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1906. Price 6s. net.

8vo volume, containing 354 pages of subject matter with 33 illustrations, and including an Appendix with general information, tabular matter, and a bibliographic list of books on Clayworking, concluding with an alphabetical index.

The subject matter is classified under the following heads:—I. Materials used in Clayworking. II. Preparation of the Clay. III. Machinery. IV. Transport, Conveyors, &c. V. Drying and Driers. VI. Engobing and Glazing. VII. Setting and Charging. VIII. Kilns. IX. Firing. X. Discharging, Sorting, Packing, and Despatching. XI. Defects. XII. Waste. XIII. Tests, Analysis, and Control.

TECHNISCH-CHEMISCHES JAHRBUCH, 1904. Ein Bericht über die Fortschritte auf dem Gebiete der chemischen Technologie. Herausgegeben von Dr. Rudolf Biedermann. Druck und Verlag von Friedrich Viewèg und Sohn. 27'ster Jahrgang. 1906. Price M.12.

8vo volume, containing 642 pages of subject matter, with 50 illustrations, and an alphabetical index of names and subjects. The matters treated of in the text are as follows:—I. Iron. II. Aluminium and noble metals. III. Gold and Silver. IV. Copper. V. Zinc. VI. Lead. VII. Nickel, Manganese, and Chromium. VIII. Tin and other metals. IX. Sulphur and Sulphuric Acid. X. Alkali Industry. XI. Electro-chemistry. XII. Ammonia and Cyanogen Compounds. XIII. Alkaline Earths, &c. XIV. Gases. XV. Silicon, Carbon, Arsenic, and Antimony. XVI. Glass. XVII. Earthenware, &c. XVIII. Cement and Artificial Stone. XIX. Explosives and Matches. XX. Illuminants. XXI. Fuels, &c. XXII. Sugar. XXIII. Starch and Glucose. XXIV. Fermentation Industries. XXV. Fats, Soaps, and Resins. XXVI. Essential Oils and Scents. XXVII. Water. XXVIII. Foodstuffs. XXIX. Organic Products. XXX. Albuminoids, &c. XXXI. Dyestuffs. XXXII. Textile Industries. XXXIII. Paper. XXXIV. Photography. XXXV. Tanning and Glue, &c. XXXVI. Manures, &c., Disinfection. XXXVII. Apparatus. XXXVIII. New Books. XXXIX. Register of Patents, &c.

L'OZONE. Emile [illegible]. Professeur de Physique et de l'Electricité [illegible] Arts et Métiers de Lima (Pérou). H. Dunod et E. Pinat, 49, Quai des Grands-Augustins, Paris. 1906. Price 2 fr.

PAMPHLET, containing 24 pages of subject matter, and 9 illustrations.

The matters treated of are the following:—I. General Considerations and Discovery of Ozone. II. Nature and Production. III. Ozone in Nature, and Influence on Animal Life. IV. Ozone as Bactericide. V. Destruction of Miasma. VI. Ozone in Medicine. VII. Industrial Preparation by Electricity. VII. Sterilisation of Air and Water. IX. Industrial Applications of Water thus Sterilised. X. Ageing of Wine and Spirit. XI. Purification of Sugar Juice. XII. Bleaching of Starch, Textiles, &c.

I SOFFIONI BORACIFERI E LA INDUSTRIA DELL'ACIDO BORICO IN TOSCANA. Relazione del Prof. Raffaello Nasini. Pubblicata in Occasione del vi Congresso Internazionale di Chimica Applicata che si terrà in Roma nell'Aprile del 1906. Tipografia della R. Accademia dei Lincei. Roma. 1906.

4TO volume, containing 109 pages of subject matter, and an index. The latter part of the volume includes five pages devoted to a bibliographic index of works on the subject of Boric Acid. The text is illustrated with 55 engravings, and the subject matter is classified under the following heads:—I. Dedication to the Count Florestano de Larderel. II. General Description of the Boric Acid Regions. III. Description of the individual localities where Boric Acid is produced. IV. History of the Boric Acid Industry. V. Manufacture of Boric Acid and of other Products. VI. Statistical Notes on the Production of Crude and Refined Boric Acid, and on the Commercial Aspect of these Products. VII. Scientific Observations and Considerations. VIII. Appendix. IX. Bibliography.

ALKALI, &C., WORKS REGULATION ACTS, 1881 AND 1892. Forty-second Annual Report on Alkali, &c., Works, by the Chief Inspector. 289. Price 8d.

ACCORDING to this report the number of works now registered under the above-mentioned Acts in England, Ireland, and Wales is 1068; there are also 137 works registered in Scotland, bringing the total number of works registered in the United Kingdom to 1205. These numbers show an increase of 28 scheduled and registered works as compared with 1904.

III.—Destructive Distillation, Tar Products, Petroleum, and Mineral Waxes	921
IV.—Colouring Matters and Dyestuffs	921
V.—Preparing, Bleaching, Dyeing, Printing and Finishing Textiles, Yarns, and Fibres	924
VI.—Colouring Wood, Paper, Leather, &c.	—
VII.—Acids, Alkalis, and Salts, and Non-Metallic Elements	926
VIII.—Glass, Pottery, and Enamels	929
IX.—Building Materials, Clays, Mortars, and Cements	929
X.—Metallurgy	930
XI.—Electro-Chemistry and Electro-Metallurgy	935
XII.—Fatty Oils, Fats, Waxes, and Soaps	937
XIII.—Pigments and Paints; Resins, Varnishes, &c.; India-Rubber, &c.	938
XIV.—Tanning; Leather; Glue, Size, Bone, and Horn; Ivory and Substitutes	941
XV.—Manures, &c.	942
XVI.—Sugar, Starch, Gum, &c.	942
XVII.—Brewing, Wines, Spirits, &c.	945
XVIII.—Foods; Sanitation; Water Purification; and Disinfectants	948
XIX.—Paper, Pasteboard, Cellulose, Celluloid, &c.	950
XX.—Fine Chemicals, Alkaloids, Essential Oils, and Extracts	951
XXI.—Photographic Materials and Processes	952
XXII.—Explosives, Matches, &c.	953
XXIII.—Analytical Chemistry	953
XXIV.—Scientific and Technical Notes	957

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—6*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* (post free, 11*s.*). A second volume (1896—1905) is in preparation. The authors' name index is now in the press, and the subject matter index will follow in 1907. The whole will form a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy, or 11*s.*, post free. A form of application for this purpose will shortly be issued.

CORRECTIONS FOR DECENNIAL INDEX.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

Bauer, H. F., l/o Canada; 809, McAllister Avenue, Waukegan, Ill., U.S.A.

Carey, Wm. G., l/o Clapton; Moulton Settlement, Leysian Mission, City Road, London, E.C.

Coffman, H., l/o South Albany Street; 314, East Seneca Street, Ithaca, N.Y., U.S.A.

Crighton, W. H., 138 (not 38), Evering Road, Stoke Newington, N.

Green, Prof. Arthur G., l/o Brondesbury; 49, Cardigan Road, Headingley, Leeds.

Irlam, H. A., l/o East Street; 83, St. Mary's Road, Faversham, Kent.

Larter, A. T., l/o Basingstoke; "Coolavin," St. Stephen's Road, Hounslow.

Leman, W. T., l/o Beaumont; c/o The Texas Co., Port Arthur, Texas, U.S.A.

Liddle, W. T., l/o Jamaica; 14, Willows Avenue, Ansdell, Lytham.

Lunge, Prof. Dr. G., l/o Steinwiesstrasse; Rämistrasse 56, Zurich V, Switzerland.

McCourt, C[illegible], l/o Clapham; 7, Malwood Road, Balham Hill.

Myl[illegible], l/o Kingstown; 15, St. Leo Mansions, [illegible] Gardens, London, S.W.

Prentice, Jas., l/o Glasgow; Cossipore Sugar Works, Cossipore, Calcutta, India.
Shepherd, R. des F., l/o Huxley Street; Central Laboratory, Rhodes, Manchester.
Short, Andrew, l/o Newcastle; all communications to Choppington, Morpeth.
Smith, Jas., l/o Milner Road; 80, Ampthill Road, Aigburth, Liverpool.
Stiff, John T., l/o Northfleet; 60, Parrock Street, Gravesend, Kent.
Tankard, Arnold R., l/o Birmingham; 82, Llanthewy Road, Newport, Mon.
Tyrer, Thos.; Journals to 14, Sandwell Mansions, West End Lane, N.W.
Weissmüller, E. C., l/o Stanley Villas; Hill Crest, The Heath, Runcorn.
Wilson, J. H., l/o London; 8, Friar's Stile Road, Richmond, S.W.
Yates, Arthur, l/o Manchester; (Journals), Lebong Donok, Benkoelen, Sumatra; and (subscription), c/o E. Whiteley, 9, Cedar Street, North Shore, Blackpool.

Change of Address Required.

Parker, E., l/o Rushford Park, Levenshulme.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 20,669. Price. Furnaces of tunnel dryers. Sept. 18.
,, 20,813. Baron, and Fuel Saving and Water Treating Co. Regulating the respective quantities of two liquids to be mixed as they flow. Sept. 19.
,, 20,894. Allison (Christ). Apparatus for separating substances of different specific gravities.* Sept. 20.
,, 20,918. Jury. Apparatus for producing extracts by diffusion and concentration. [Fr. Appl., Oct. 7, 1905.]* Sept. 20.
,, 21,337. Zeitlin. Mechanical production of high vacua. Sept. 26.
,, 21,424. Aktiebolaget Separator. Centrifugal separators. [Appl. in Sweden, Oct. 23, 1905.]* Sept. 27.
[C.S.] 18,877 (1905). Incandescent Heat Co., and Smallwood. *See under* X.
,, 21,116 (1905). Schmatolla. Vertical kilns. Sept. 26.
,, 10,187 (1906). Hemmerling. Filter presses. Oct. 3.
,, 10,852 (1906). Forsbach. Muffle furnaces. Sept. 26.
,, 11,877 (1906). Lanza. *See under* XII.

II.—FUEL, GAS, AND LIGHT.

[A.] 20,630. Reid. Apparatus for generating gas from liquid hydrocarbons. Sept. 17.
20,851. Ruane. Fuel for firing and heating furnaces. Sept. 20.
20,858. Pearson. Means for mixing combustible gases with steam, air, &c., and consuming them in furnaces.* Sept. 20.
20,953. Daudin. *See under* VIII.
21,284. Dowson. Manufacture of producer gas. Sept. 22.
[A.] 21,289. Koppers. *See under* III.
,, 21,493. Armstrong. Manufacture of coke and ovens therefor. Sept. 26.
,, 22,516. British Thomson-Houston Co. (Siemens Electrical Co.). Electrodes for electric arc lamps. Sept. 28.
,, 21,538. Wright. Coking ovens. Sept. 29.
,, 21,556. Hutchins. Gas-producer apparatus. Sept. 29.
,, 21,578. Jahoda, and Elektrische Glühlampfabrik. Manufacture of incandescing lamp filaments. Sept. 29.
[C.S.] 18,930 (1905). Boyd and McKay. Generation of power gas. Sept. 26.
,, 19,617 (1905). Bemelmans. Gas generator furnaces. Sept. 26.
,, 24,634 (1905). Still and Adamson. Incandescent gas mantles. Oct. 3.
,, 27,001 (1905). Hiby. Coke ovens. Oct. 3.
,, 3237 (1906). Miller. Burner for liquid combustibles. Sept. 26.
,, 8276 (1906). Bauke. Suction gas producers. Sept. 26.
,, 8778 (1906). Bauke. Suction gas generators. Sept. 26.
,, 10,945 (1906). Fitzpatrick (Weickart). Burner for liquid combustibles for producing a Bunsen flame. Sept. 26.
,, 12,076 (1906). Economic Safety Gas Co., and Fowler. Apparatus for producing carburetted air. Sept. 26.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 20,670. Wilson and Downing. Apparatus for vaporising petroleum and other fats and oils. Sept. 18.
,, 21,269. Koppers. Eliminating without danger the combustible but low grade gases of dry distillation or gasification. [Ger. Appl., Oct. 23, 1905.]* Sept. 25.
[C.S.] 19,502 (1905). Butterfield and Watson. *See under* XVIII*B*.
,, 3892 (1906). Thompson (Soc. d'Eclairage et de Chauffage proc. A. Guy). Vaporisation of petrol and other oils. Sept. 26.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 20,633. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series.* Sept. 17.
,, 20,802. Newton (Bayer und Co.). Manufacture of a new dyestuff of the oxazine series and its leuco-derivative. Sept. 19.
,, 20,837. Johnson (Badische Anilin und Soda Fabrik). Manufacture of anthracene compounds and colouring matters therefrom. Sept. 19.
,, 21,009. Lake (Farb. Mülheim vorm. Leonhardt und Co.). Manufacture of colouring matter. Sept. 21.
[C.S.] 22,513 (1905). Read Holliday and Sons, Turner and Dean. Manufacture of blue and black colouring matters. Oct. 3.
,, 23,740 (1905). Vidal. Production of colouring matters. Sept. 26.
,, 17,162 (1906). Kalle and Co. Manufacture of red colouring matters. Oct. 3.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 21,082. Evans. Process for dyeing cotton in union fabrics of cotton and wool. Sept. 22.
,, 21,444. Friedländer. Manufacture of artificial threads. [Ger. Appl., Sept. 23, 1905.]* Sept. 24.

[illegible] 21,363. [illegible] dyeing vegetable fibres.* Sept. 26.

" 21,374. Yates. Washing process and composition for dry cleaning fabrics.* Sept. 26.

" 21,502. Tyrone. Process in the finishing of linen, imitation silk, cotton, and like fabrics and materials. Sept. 29.

[C.S.] 25,893 (1905). Feilmann. Manufacture of products for use in dyeing and printing, and as pigments. Oct. 3.

" 8910 (1906). Lecœur.* *See under* VII.

" 12,938 (1906). Jahr. Drying loose wool yarn, &c., in the form of cops or strands. Oct. 3.

" 15,133 (1906). Thiele, and Soc. Gen. de la Soie Artificielle Linkmeyer. Method of producing cellulose threads. Sept. 26.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

[C.S.] 21,902 (1905). Pärr and Kopetz. *See under* IX.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 20,807. Humphrey. Separating and collecting the constituents of atmospheric air. Sept. 19.

" 21,182. Bambridge. Recovery of sulphur from the sulphur salts of the alkaline earths and metals. Sept. 25.

" 21,461. Garroway. Manufacture of acetate of alumina and by-products. Sept. 28.

[C.S.] 19,189 (1905). Stuart-Bailey. Manufacture of nitrate of soda and recovery of by-products. Sept. 26.

" 19,502 (1905). Butterfield and Watson. *See under* XVIIB.

" 27,009 (1905). Johnson (Badische Anilin und Soda Fabrik). *See under* XI.

" 8910 (1906). Lecœur. Purification of ammoniacal copper solutions. Sept. 26.

" 9971 (1906). Poulenc. Extraction of lithium as lithium carbonate from its ores. Oct. 3.

" 11,820 (1906). Berton. Kilns for burning lime. Oct. 3.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 20,955. Deselle. Regenerative gas furnaces for glass and other purposes.* Sept. 21.

[C.S.] 24,913 (1905). Gottlieb. Decoration of enamel, porcelain, glass, &c. Oct. 3.

" 25,639 (1905). Thornton, Sharp, Ingle and Stanley. Kilns for burning or fixing colours or glaze on glass, earthenware, &c. Sept. 26.

" 15,293 (1906). Chambers. Manufacture of glass. Sept. 26.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

[A.] 20,608. Ford. Manufacture of artificial stone. Sept. 17.

" 20,901. Hornell. Compositions for artificial marble, stone, and the like.* Sept. 20.

" 21,576. Hippa. Hardening and rendering durable coloured or uncoloured objects made of natural stone, plaster of Paris, magnesite, cement, and the like.* Sept. 29.

[C.S.] 19,471 (1906). Rowen. Manufacture of bricks. Sept. 26.

" 21,902 (1905). Pärr and Kopetz. Apparatus for impregnating or colouring wood. Sept. 26.

" [illegible] (1906). Smith, Tagye and Tagye. Cement. Oct. 3.

" [illegible] (1906). Hermann. Manufacture of a dust-[illegible] [illegible]

X.—METALLURGY.

[A.] 19,184 and 19,184A (1906). Tavernier. Manufacture of [illegible] Sept. 19.

" 20,520. Herdsman. Treating [illegible] powdered or small ore. Sept. 19.

" 21,110. Tucker. Recovery of zinc. Sept. 24.

" 21,423. Redruth Foundry Co., and Pryor. Apparatus for pulverising and amalgamating ore. Sept. 27.

" 21,440. McIvor and Fradd. Treatment of [illegible] residues. Sept. 27.

[C.S.] 18,877 (1905). Incandescent Heat Co., and Smal wood. Smelting, crucible, heating, annealing and like furnaces. Sept. 26.

" 19,198, 19,198A, and 19,198B (1905). Faschen Manufacture of metallic alloys. Oct. 3.

" 19,282 (1905). Claessen. Process for improvin aluminium alloys by heating and chilling. Oct.

" 19,781 (1905). Simpson. Method of refinin metals and apparatus therefor. Oct. 3.

" 19,781A (1905). Simpson. Crucibles for mixing an alloying metals. Oct. 3.

" 19,839 (1905). Worsey and Hoal. Treatment composite ores or zinc waste, and manufacture zinc white and other products. Oct. 3.

" 22,900 (1905). Enke. Sulphatisation of ores an their by-products. Oct. 3.

" 26,980 (1905). Heskett. Process for obtainin metals from their sulphides. Sept. 26.

" 3528 (1906). Day. Process for smelting ores an converting mattes. Sept. 26.

" 4199 (1906). Brunet. *See under* XXIIA.

" 9996 (1906). Defays. Manufacture of steel i Martin furnaces. Oct. 3.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 20,712. Roberts, Roberts and Jaffray. Electro deposition of metals and alloys.* Sept. 18.

" 20,716. Roberts, Roberts and Jaffray. Electro deposition of metals and their alloys.* Sept. 18.

" 21,081. Cowper-Coles. Manufacture of iron tube by electrodeposition. Sept. 22.

" 21,082. Cowper-Coles. Manufacture of iron cylinders, tubes, &c. Sept. 22.

" 21,100. Ashcroft. Electrolysis of haloid salts and compounds. Sept. 22.

" 21,336. Neville, Guye and Guye. Application of the electric arc for producing reactions in a gaseous mass. Sept. 26.

" 21,349. Cowper-Coles. Electrolytic production of copper wire, strip, or the like. Sept. 26.

" 21,416. Kjellin. Electrical furnaces. [Appl. in Sweden, March 5, 1906.]* Sept. 27.

" 21,583. Cowper-Coles. Electrolytic manufacture of metal wire, strip, or the like. Sept. 29.

[C.S.] 18,931 (1905). Ruzicka. Primary batteries. Sept. 26.

" 20,143 (1905). Whitehead and Marino. Treatment of wood to be used in electrochemical apparatus. Sept. 26.

" 20,500 (1905). Hatfield, and Reason Manufacturing Co. Mercury electrolytes for electrolytic cells. Oct. 3.

" 23,526 (1905). Platschick. Electrical furnaces. Sept. 26.

" 27,009 (1905). Johnson (Badische Anilin und Soda Fabrik). Electrolytic production of chromic acid. Sept. 26.

" 8452 (1906). Pauling. Electric furnaces for treating gases. Sept. 26.

" 10,219 (1906). Rink. Apparatus for the electrolytic decomposition of alkaline chloride solutions by means of mercury cathodes. Sept. 26.

" 10,316 (1906). Reilly. Submersible apparatus for electrically heating liquids. Sept. 26.

XII.—FATTY OILS, FATS, WAXES AND SOAP.

[A.] [illegible] Sept. 17.

[A.] 21,072. Pitchford and Knott. Liquid soap or detergent. Sept. 22.
„ 21,172. Boult (Van de Kerckhove). Treatment of vegetable oils.* Sept. 24.
[C.S.] 11,877 (1906). Lanza. Filtering apparatus, particularly adapted for the extraction of stearine from fatty acids in sulpho-oleic acid solution. Oct. 3.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

[A.] 20,702. Villard. Composition for paints. Sept. 18.
[C.S.] 19,190 (1905). Fireman. Manufacture of printing ink pigments. Oct. 3.
„ 19,839 (1905). Worsey and Hoal. *See under* X.
„ 25,693 (1905). Feilmann. *See under* V.
„ 4199 (1906). Brunet. Obtaining lithopone from complex ores and other substances. Sept. 20.

(C.)—INDIA-RUBBER.

[A.] 21,493. Claessen. Manufacture of masses of the nature of vulcanite or india-rubber.* Sept. 28.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

[A.] 20,918. Jury. *See under* I.
[C.S.] 1850 (1906). Johnson (Badische Anilin und Soda Fabrik). Decolorisation of extracts containing tannin. Sept. 26.

XVI.—SUGAR, STARCH, GUM, &c.

[A.] 20,638. Cross and Briggs. Manufacture of xanthates of certain carbohydrates. Sept. 17.
„ 21,365. Calico Printers' Association, Browning and Barlow. Manufacture of soluble starch and dextrine. Sept. 27.

XVII.—BREWING, WINES, SPIRITS, &c.

[A.] 20,936. West. Manufacture of alcohol from peat. Sept. 21.
„ 21,250. Sureties. Utilisation of spent hops. Sept. 25.
„ 21,326. Hellwig. Washing apparatus for spent malt or grain.* Sept. 26.
„ 21,567. Elektrochemische Werke. *See under* XX.
[C.S.] 18,636 (1905). House. Fermenting vats. Sept. 26.
„ 18,637 (1905). House. Mash tuns and infusion decoction and digester vessels. Sept. 26.
„ 26,041 (1905). Cowell. Treatment of malt. Oct. 3.
„ 5135 (1906). Vloeberghs. Process of fermentation. Sept. 26.
„ 9886 (1906). Pollak. Conversion of diastatic malt extracts into solid form for rendering same durable. Sept. 26.
„ 13,563 (1906). Nilsson and Jonson. Improving the quality of wine and the like. Sept. 26.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

[A.] 21,139. Michaëly. Manufacture of food for animals.* Sept. 24.

(B.)—SANITATION; WATER PURIFICATION.

[A.] 20,779. Guy. Manufacture of media for bacteria beds. Sept. 19.
„ 20,792. Hale. Treating, softening, and filtering water. Sept. 19.
„ 21,276. Taylor and Berry. Liquid sprinkler. Sept. 25.
[A.] 21,395. Carey and Lawrence. Method of treating softening, and purifying water. Sept. 27.
„ 21,444. Lyons. Apparatus for the bacteriologic treatment of fæcal matter, waste water, sewag and the like. Sept. 27.
[C.S.] 19,502 (1905). Butterfield and Watson. Destru tive distillation of sewage sludge and oth organic waste for the recovery of by-produc such as ammonia and oil, and utilisation of th residue. Oct. 3.
„ 26,527 (1905). Westfope and Cooper. Sterilisin softening, and heating water and other liquid and apparatus therefor. Sept. 26.

(C.)—DISINFECTANTS.

[A.] 20,680. Houghton. Antiseptic compounds. [U.S Appl., Sept. 25, 1905.]* Sept. 18.

XIX.—PAPER, PASTEBOARD, &c.

[A.] 21,469. Jackson. Paper, and the manufactur thereof. Sept. 28.
[C.S.] 24,563 (1905). Pearson. Substance for renderin paper impervious to oil and grease. Oct. 3.
„ 10,228A (1906). Johnson (Badische Anilin un Soda Fabrik). Manufacture of substance resembling celluloid. Oct. 3.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 20,586. Daege, Knoll and Knoll. Manufacture o santalol carbonate.* Sept. 17.
„ 20,918. Jury. *See under* I.
„ 21,165. Johnson (Badische Anilin und Soda Fabrik) Manufacture of camphor. Sept. 24.
„ 21,171. Goldsmith, and British Xylonite Co Manufacture of camphor. Sept. 24.
„ 21,180. Goldsmith, and British Xylonite Co Manufacture of camphene. Sept. 24.
„ 21,567. Elektrochemische Werke. Process of de priving alcohols, and especially ethyl alcohol, o water. [Ger. Appl., Sept. 29, 1905.]* Sept. 29
[C.S.] 21,814 (1905). Spurge (Spurge). Manufacture o aldehydes. Oct. 3.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 21,189. Thornton. Photographic films. Sept. 25
„ 21,584. Neue Photographische Ges. Process fo converting silver pictures into pictures i higher oxides of manganese, and for toning silve pictures. [Ger. Appl., Oct. 12, 1905.]* Sept. 29
[C.S.] 13,032 (1905). Mallabar. Printing and developing photographs on silver chloride paper. Oct. 3.
„ 22,725 (1905). Zimmermann (Chem. Fabr. au Actien, vorm. E. Schering). Production o coloured photographs. Oct. 3.
„ 7935 (1906). Bloxam (Neue Photographische Ges.). Reproducing pictures by imprinting an original picture that has been treated with hydrogen peroxide. Sept. 26.

XXII.—EXPLOSIVES, MATCHES, &c.

[A.] 20,889. Luis and Williamson. Explosives.* Sept. 20.
„ 21,240. Weyel. Explosive, and process of making same.* Sept. 25.
[C.S.] 437 (1906). Silbercad. Explosives for use in torpedoes and the like. Sept. 26.
„ 8304 (1906). Röhrecht. Manufacture of smokeless gunpowder. Oct. 3.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

[A.] 21,342. Biddulph. Means of chemical analysis. Sept. 26.

Journal and Patent Literature.

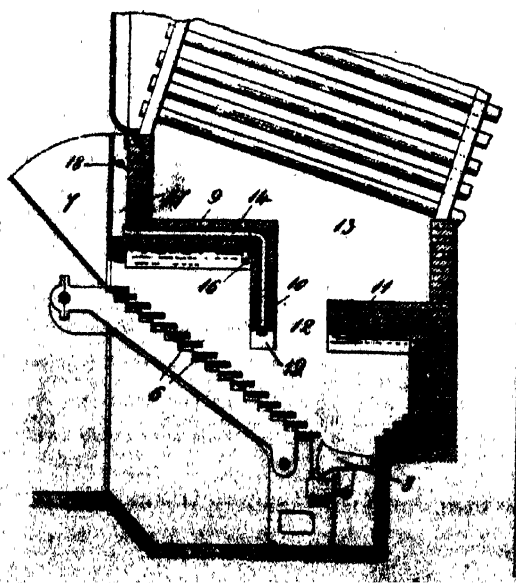
I.—PLANT, APPARATUS, & MACHINERY.

(*Continued from page 875.*)

English Patents.

Atomising liquids; An improved machine for ——. P. Kestner, Lille, France. Eng. Pat. 20,697, Oct. 12, 1905.

A drum, formed of wire-gauze or parallel wires, is rotated at a high speed on an axis, and the liquid to be atomised is sprayed into the drum. The edges of the wires, on the outside of the drum, are sharpened, so that the liquid leaves the drum from the summits of very sharp angles or points. It is stated that with a drum 30 cm. diameter and 15 cm. deep, 20 tons of water have been atomised in an hour.—W. H. C.



Boiler compositions [for preventing incrustation]. F. Smith and F. J. E. Smith, Grantham. Eng. Pat. 21,330, Oct. 20, 1905.

The claim is for a boiler composition composed of fluid extracts of bark, hemlock, and potatoes, mixed with sodium carbonate or a similar alkali. The extracts of bark and potatoes are made separately, by boiling with water, and the other ingredients are subsequently added. Twitch grass and grains may be added to the extract, if desired.—W. H. C.

Feed-water of steam boilers; Treatment of the ——. W. Clark, Hamilton, Lanarkshire. Eng. Pat. 22,148, Oct. 31, 1905.

The claim is for the process of treating the feed water with flue gases or with carbon dioxide, previous to its introduction into the boilers. This is effected either by spraying the feed water into the flue, and collecting the treated water in a reservoir, or by withdrawing the gases from the flue by a fan, and forcing them through the water in the feed tank.—W. H. C.

Smoke-consuming furnace. J. S. S. Fulton, New York. Eng. Pat. 24,620, Nov. 28, 1905. Under Int. Conv., April 10, 1905.

The fuel is fed from the hopper, 7, and passes down the inclined grate bars, 6, to the bottom, 5, whence the ashes are discharged. A primary supply of air reaches the fuel through the bars, 6, and the gases generated, along with the smoke, are deflected back upon the fuel by the walls, 9, 10, and 11. A secondary supply of air enters through the channel, 17, controlled by the damper, 18, and is heated by passing through a series of tubes, 14, set in the walls, 9 and 10. The tubes terminate alternately at the points indicated by the figures, 16 and 19, and the mixture of gases and air passes on through the opening, 12, into the combustion chamber, 13.—W. H. C.

Drying drums for drying sediments and other wet materials. E. Vial, Brussels. Eng. Pat. 5867, March 19, 1906.

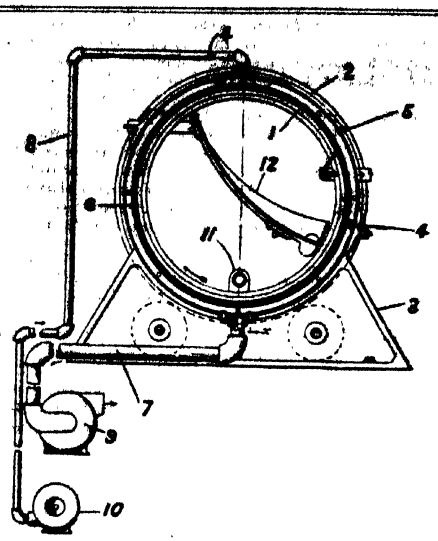
See Fr. Pat. 364,291 of 1906; this J., 1906, 893.—T. F. B.

United States Patents.

Pyrometer. F. J. Albrecht, Pittsburg, Pa. U.S. Pat. 830,278, Sept. 4, 1906.

A composite tube, composed of an outer tube of brass and an inner tube of iron, which are rigidly fastened together at their outer ends by a nut, is attached to a casing containing a dial and pointer, and mechanism for operating the latter. The casing is formed of two sections provided with "lugs," by which they are held together, and has the inner end of the outer brass tube rigidly attached to it. The inner end of the iron tube projects beyond the end of the brass tube into the casing, and is attached by an arm and lever to the dial mechanism. The differential expansion of the two tubes of iron and brass under the influence of heat is indicated on the dial. —W. H. C.

Dryer; Revolving ——. R. C. Hills, Denver, Colo. U.S. Pat. 830,435, Sept. 4, 1906.



Two concentric cylinders, arranged so as to leave an annular space between them, are supported so that they can be rotated on rollers in a position slightly inclined to the horizontal. The materials to be dried are delivered on to a floor at the upper end of the cylinders, and are carried through the inner cylinder, and delivered at the lower end by ploughs or rabbles attached to an endless chain, which passes through the inner cylinder, and returns over the top of the outer cylinder on suitable rollers. The heating medium enters the annular space at the lower end, and leaves at the upper end.—W. H. C.

Dryer; Vacuum ——. E. Passburg, Berlin. U.S. Pat. 830,521, Sept. 11, 1906.

See Ger. Pat. 166,945 of 1903; this J., 1906, 933.—T. F. B.

Liquids from solids; Apparatus for separating ——. E. P. Starbird, Victorville, Cal. U.S. Pat. 830,624, Sept. 11, 1906.

The apparatus consists of an inner filter-cylinder, 1, which is rotated in the direction indicated by the arrow, and enclosed in an outer stationary cylindrical casing, 2, supported on the stand, 3. The annular space between the cylinders is divided by the partitions, 4, into an upper space, 5, and a lower space, 6. Suction is applied to the lower space, 6, through the pipe, 7, by the pump, 9, and air is forced by the pump, 10, through the pipe, 8, into the upper space, 5, producing a pressure. The liquid to be filtered is fed into the interior of the inner cylinder, which has open ends, by the pipe, 11, extending the whole length of the cylinder, and [illegible] of the filter. As the filter revolves the liquid is drawn through the filtering medium into the lower space, 6, and the solid portion remains behind, [illegible]

to the inner surface, from which it is loosened, as the cylinder continues to rotate, by the pressure in the space, 5, and is finally removed by the scraper, 12.—W. H. C.

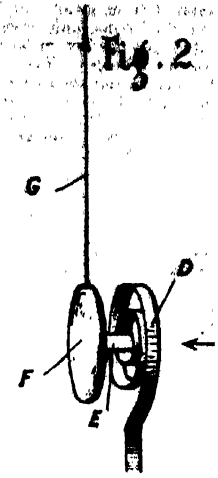
FRENCH PATENTS.

Drying apparatus; Rotary ——. R. G. Poncet. Fr. Pat. 364,304, March 16, 1906.

A HORIZONTAL or inclined rotary cylinder is provided on its inner surface with a number of longitudinal shelves, which raise the material under treatment from the bottom of the cylinder, and allow it to descend on to a series of longitudinal tubes, mounted in the ends of the cylinder, and extending the whole length of same. These tubes, of any convenient section, have their walls extended tangentially to form longitudinal ledges, preferably helical in shape, by means of which the material is turned over, and discharged from one tube to the other, finally reaching the bottom of the cylinder, from which it is again raised by the aforesaid shelves. Means are provided for drawing a current of hot air through the cylinder.—C. S.

Drying pulverulent and other materials; Process and apparatus for ——. J. Savary. First Addition dated March 20, 1906, to Fr. Pat. 362,315, Jan. 10, 1906 (this J., 1906, 683).

THE addition consists in arranging the drying chambers in tiers, and in providing them with double-jacketed bottoms which are protected by an insulating covering. The materials to be dried are moved through the chambers by blades or stirrers, carried on hollow rotating shafts which pass through the chambers. The heating medium is caused to pass through the hollow shafts as well as through the jackets.—W. H. C.



Clarifying liquids; Apparatus for mechanically ——. W. Rottmann, and J. A. Miller und Co. Fr. Pat. 365,265, March 29, 1906.

See Eng. Pat. 7878 of 1906; this J., 1906, 994.—T. F. B.

Radio-pyrometer; Expansion ——. C. Féry. Fr. Pat. 364,884, April 5, 1906.

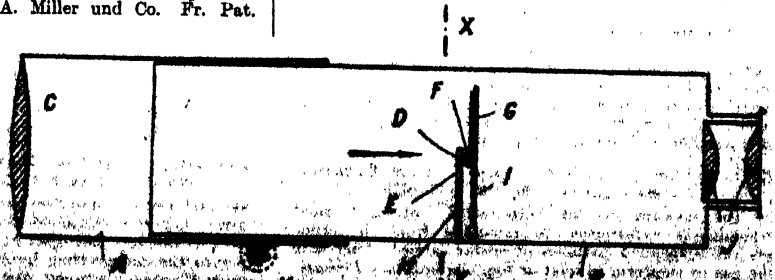
TWO sliding tubes, A, B, are fitted at one end with a lens, C, and at the other with an eye-piece, J. At the focus of the lens, C, is placed a compound spiral, D (see Fig. 2), about 1 cm. long, 1 mm. wide, and 0·02 mm. thick, composed of strips of platinum and silver which expand unequally under the influence of heat. The spiral is supported on a light arm, H (Fig. 1), made of German silver or some other badly conducting metal, and has a disc, F, attached by a short bar, E, made of copper or some other good metallic conductor, to the other end. The face of the disc, F, which is turned towards the eye-piece, J, is polished to prevent radiation, and the other side, the spiral itself, and the connecting piece, E, are covered with lampblack to render them capable of easily absorbing heat rays. The apparatus is focussed by the rack and pinion, K, so that the heat rays from the object the temperature of which is to be determined, and toward which the lens, C, is directed, are concentrated upon th spiral, and a pointer, G, carried on the disc, F, indicates th temperature on the scale, I. The pyrometer is graduate by observing the point of fusion of bodies of know melting point, or by comparison with another therm meter.—W. H. C.

Fig. 2

GERMAN PATENT.

Evaporating apparatus; Vertical ——. A. Gude Ger. Pat. 169,243, May 20, 1905. Addition to Ge Pat. 160,670, Feb. 23, 1904.

IN the apparatus described in Ger. Pat. 160,670 (this J. 1905, 1162), the liquid to be evaporated was supplie to the heating tubes by means of a distributor, which fe it to pipes discharging vertically into a chamber belo the vertical heating tubes. It has been found that with thi arrangement the liquid rises more rapidly in the heatin tubes opposite the outlets of the supply pipes than in th others. To overcome this defect, it is proposed in th present patent to bend over horizontally the ends o the supply pipes leading from the distributor.—A. S.



II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 878.)

Oils used for gas-making purposes; Composition an valuation of ——. R. Ross and J. P. Leather. Analyst 1906, 31, 284—298.

IN a former communication (this J. 1902, 676) the author showed the possibility of judging the value of an oil fo gas-making purposes by the results of certain chemica and physical tests. Since then they have made experi

Fig. 1

mental determinations of the value of different classes of hydrocarbons, and have examined a large number of typical gas-oils by methods substantially the same as those used before. Their results, given in detail, have led them to the following conclusions:—(1) Open chain compounds have the greatest value for gas-making purposes. (2) Double bonds in the chain reduce the value somewhat. (3) A considerable reduction in the value is caused by the presence of one or more rings. (4) Ring compounds are more valuable in proportion as they are more fully hydrogenised. (5) Benzene rings are practically valueless for "cracking" purposes.

As regards the relationship between specific gravity and refractive index, it was found that the specific refraction of open chain compounds, whether paraffin or olefine, was about 0·555 to 0·560. The specific refraction was reduced by the presence of a hexamethylene ring, and still more so by a saturated double ring, whilst, on the other hand, this value was increased to a considerable extent by the presence of an unsaturated ring, as in the case of tetrahydronaphthalene.

In illustrating the application of these conclusions, the authors here only compare the fractions boiling between 280° and 300° C., these being present in all the oils examined. In the case of Pennsylvanian oils the specific refraction of this fraction (0·556) was lower than in oils of other origin, and pointed to the presence of a large amount of paraffins and olefines. But the specific gravity of the oil (0·833) and that of the substance frozen out from ether-alcohol solution (0·849) indicated a mixture of paraffins, olefines, and "paraffinoid" bodies, *i.e.*, compounds with one or more long open chains, together with a hexamethylene ring, and this conclusion was confirmed by the high valuation figure of these oils (14,967 to 15,944). In like manner the same fraction from Russian oils was judged to consist, in the main, of paraffinoid compounds. Texas oil, in which the fraction had a sp. gr. of 0·895 and a specific refraction of 0·549, apparently contained a considerable amount of fully hydrogenised complex ring compounds not of a paraffinoid character—a conclusion confirmed by the valuation figure. In the case of Roumanian oils the average specific gravity (0·882) and specific refraction (0·557) of the fraction pointed to the presence of a considerable proportion of unsaturated ring compounds. Certain Roumanian oils, however, came between Russian and Pennsylvanian oils in their characteristics. Borneo oil was remarkable for containing a larger proportion of unsaturated and partially hydrogenised ring compounds than any of the other oils. This was shown by the high specific gravity (0·936) and low specific refraction (0·560) of the fraction, which were in accordance with the remarkably low valuation figure of the oil (7425 to 8067). Kansas oil, the fraction from which had a specific gravity of 0·850 and specific refraction of 0·555, was judged to be inferior to Pennsylvanian oil for gas-making purposes. Californian oil apparently contained a considerable amount of paraffins and paraffinoid compounds, together with some incompletely saturated compounds. The sample of Galician oil examined was concluded to contain a somewhat greater quantity of open chain compounds than the Russian oils did. Grosny oils resembled Russian oils, but were of less value for gas-making, probably owing to their containing less true paraffins and more paraffinoid substances. Scotch gas-oils yielded fractions of low specific gravity and high specific refraction (0·560), but the valuation figures were poorer than was anticipated from these constants. As these oils were the products of destructive distillation the authors inferred that they probably consisted of a considerable amount of olefines, together with substances containing benzene rings, the latter, judging by the low specific gravity, being probably of a paraffinoid character.—C. A. M.

Tar; Removal of —— from water gas. E. H. Earnshaw. J. Gas Lighting, 1906, 96, 637—639.

In the manufacture of carburetted water-gas, great difficulty is experienced in removing from the crude gas the suspended particles of oil or tar carried along with the gas in the form of mist or fog, the ordinary Pelouze-Audouin impingement extractor, used successfully with coal gas, being inefficient with the former gas. The author has made a series of experiments to ascertain how far it is possible by suitable modifications in the size of perforation and number of plates, to construct a modified Pelouze extractor which will also effectually remove the oil-tar fog, and as the outcome of these has ascertained that the most suitable size of perforation is ¼th in. diameter, and that with nine plates spaced ½ in. apart, a very effective separation of the oil-tar fog is obtained when the flow of gas is so regulated that a loss of pressure of about 1 in. per plate is experienced. The temperature of the gas for good working must not exceed about 100° F.—H. G. C.

Arseniuretted hydrogen; Removal of —— from crude hydrogen gas. O. Wentzki. Chem. Ind., 1906, 29, 405—406.

The hydrogen is passed upwards through a cylinder packed with a mixture of two parts of dry chloride of lime and one part of moist sand or other inert material. If the column of purification material be sufficiently high, the whole of the arsenic is retained. A small quantity of chlorine is set free, but can be easily removed by passing the hydrogen through a second cylinder packed with nearly dry slaked lime.—A. S.

Tantalum and the tantalum lamp. Werner von Bolton. XIB., page 937.

English Patents.

Briquettes from fuel, ores, and the like; Manufacture of ——. J. Noll, Frankfort-on-Maine, and E. Trainer, Wolfach, Germany. Eng. Pat. 12,516, June 16, 1905. Under Int. Conv., Sept. 14, 1904.

The refuse of lixiviated cellulose or wood-pulp is mixed with powdered coal, and the whole thoroughly dried; the powder is then subjected to a pressure equal to 500 kilos. per sq. c.m., the heat thereby produced rendering the mass plastic. Good results are obtained if one mixes with 100 parts of dry coal so much cellulose lixivium as will give 8—10 parts of dry residuum.—J. H. C.

Peat and similar fuel containing a large quantity of water; Method of and apparatus for partly coking —— in conjunction with coke ovens. Oberbayerische Kokswerke und Fabrik Chemischer Produkte A.-G., Benesberg, Bavaria. Eng. Pat. 5503, March 7, 1906. Under Int. Conv., May 20, 1905.

See Fr. Pat. 357,174 of 1905; this J., 1906, 19.—T. F. B.

Fire damp (methane) or other light gas or gases in mines or other places; Apparatus for detecting the presence and volume of ——. J. McCutcheon. Eng. Pat. 24,990, Dec. 1, 1905. XXIII., page 954.

Gas manufacture [Coal gas mixed with producer gas]. R. G. Shadbolt, Grantham, Lincs. Eng. Pat. 15,955, Aug. 22, 1905.

Coal gas is made by the usual method of carbonisation, and a portion of the gas from the producer is mixed simultaneously, whilst at a high temperature, with the gas passing from the retorts. To effect this, a pipe, coated with non-conducting material, is provided between the generator and the pipe which connects the hydraulic main and the foul gas main; the two gases mingle in the connecting pipe. The quantity of producer gas introduced is determined by the suction of the exhauster commonly employed, and in order that this quantity may vary with the quantity of retort gas passing, a water loading device is attached to the steam or compensating governor of the exhauster, and so arranged as to increase the speed of the exhauster as the make of coal gas increases, and *vice versâ*.—E. B.

Carburetting apparatus. E. Grunewald, Schoneberg, Germany. Eng. Pat. 12,129, May 24, 1906.

The carburetter comprises an outer vessel containing a series of narrow concentric tubes, one end of which is closed, the other end open at the bottom. The tubes dip into the evaporating liquid, and the gas to be carburetted passes between the outer [illegible]

arranged alternately at the top and at the bottom, ledges of porous material being placed between the tubes to force the gas to follow a helical or winding path.—R. L.

Carbon dioxide; Process for the elimination of —— from the gaseous combustion products of combustion engines. P. Wimand, Cologne. Eng. Pat. 3570, Feb. 13, 1906. Under Int. Conv., Feb. 18, 1905.

For condensing the gaseous combustion products of combustion engines, especially for use in submarines, the carbon dioxide contained in the gases is fixed by adding a base, either before or after the gases have performed their work. If a volatile base, as ammonia, be used, it may be evaporated under pressure, and thus made to perform work by expansion, either separately or in combination with the combustion gases. Sodium nitrate may be heated, yielding the oxygen required for combustion, together with sodium hydroxide, which can be dissolved and used to absorb the carbon dioxide. Or, alkali peroxide may be employed to supply oxygen, or to oxidise directly carbonaceous material, in both cases producing a base suitable for absorbing the carbon dioxide.—R. L.

Gas calorimeter. J. W. B. Stokes and D. Stewart & Co. (1902), Ltd. Eng. Pat. 21,872, Oct. 27, 1905. XXIII., page 953.

Gas analysis; Apparatus for ——. W. H. Sodeau and Brady and Martin, Ltd. Eng. Pat. 12,225, May 25, 1906. XXIII., page 954.

Temperature of materials; Compositions for use in raising and maintaining the —— in the manufacture of calcium carbide and other processes. H. L. Hartenstein, Constantine, Mich., U.S.A. Eng. Pat. 10,157, May 1, 1906.

See U.S. Pat. 819,218 of 1906; this J., 1906, 544.—T. F. B.

Carbide; Manufacture of ——. H. L. Hartenstein, Constantine, Mich., U.S.A. Eng. Pats. 10,158 and 10,160, May 1, 1906.

See U.S. Pats. 819,219 and 819,221 of 1906; this J., 1906, 544.—T. F. B.

Filaments for incandescing electric lamps; Manufacture of ——. J. R. Crawford, London. Eng. Pat. 14,898, July 19, 1905.

A filament composed of a conductor of the first class, e.g., a carbon filament, is immersed in a bath composed of a pure hydrocarbon, such as benzene, in which silicon tetraphenyl or boron or silicon triethylphenyl, or other "organic compound of a metal" has been dissolved. A current is then passed through the filament to raise it to incandescence, whereby graphitic carbon and the "metal" are deposited upon it as a dense coating.—H. B.

Filaments for electric incandescent lamps; Manufacture of ——. H. Zerning, Halensee, Germany. Eng. Pat. 2554, Feb. 1, 1906.

The filaments are formed of hydrogen or nitrogen compounds of chromium, molybdenum, or tungsten, used either separately or in admixture. These compounds are obtained by reduction of the corresponding oxides by zinc powder or by some other metal which has less affinity for oxygen than magnesium, aluminium, potassium, or sodium. The product obtained is purified by treatment with acid, and after mixing with an agglomerant is formed into filaments, which are heated in an inert atmosphere by an electric current. The current strength used is about double that which the filaments will subsequently be expected to carry when in use, and the heating may be continued in an atmosphere of nitrogen until nitrogen compounds of the metals are formed.—W. H. C.

Incandescent bodies for electric lighting; Manufacture of ——. J. Imray, London. From Siemens und Halske A.-G., Berlin. Eng. Pat. 9548, April 19, 1905.

See Fr. Pat. 361,324 of 1906, following this.—T. F. B.

UNITED STATES PATENTS.

Fuel; Artificial ——. J. W. Leadbeater, Leeds. U.S. Pat. 830,086, Sept. 4, 1906.

See Fr. Pat. 364,305 of 1906, following these.—T. F. B.

Peat or turf; Apparatus for treating wet —— [for fuel making]. M. Ekenberg, Stockholm. U.S. Pat. 830,311, Sept. 4, 1906.

See Fr. Pat. 332,600 of 1903; this J., 1903, 1238.—T. F. B.

Fuel; Artificial —— and process of making same. V. J. Kuess, Tunis. U.S. Pat. 830,333, Sept. 4, 1906.

See Eng. Pat. 7481 of 1904; this J., 1904, 817.—T. F. B.

Gas; Apparatus for producing ——. W. A. Fourness, New York. U.S. Pat. 829,518, Aug. 28, 1906.

A gas generator, for making water-gas and producer gas, has a fuel-charging hole provided with a lid in its upper wall, and has a single outlet which communicates with two gas mains. The connection between the outlet and the mains is controlled by a valve in such a manner that on opening one passage, the other is closed. The generator is connected with a casing containing a heating chamber and a retort within this chamber. The heating chamber receives producer gas from the generator by a separate conduit, whilst the water-gas and producer gas issuing by the common outlet can be directed either to the retort or to the heating chamber by means of the controlling valve.—R. L.

Gas producer. W. B. Hughes, Philadelphia, Pa. U.S. Pat. 829,651, Aug. 28, 1906.

In a gas producer, a revolving body is combined with a revolving base, independent of the body, and a stationary ash receiver, into which the base extends, leaving an annular space between the latter and the receiver for the discharge of the ashes. Adjustable scrapers are arranged in the annular space for regulating the discharge.—R. L.

Gas; Apparatus for generating ——. M. D. Shaw and W. P. Rhody, Wapakoneta, Ohio. U.S. Pat. 830,015, Sept. 14, 1906.

"Crude oil" is forced from a store tank into a reservoir by a pump operated by compressed air. It is then forced by compressed air from the reservoir into flues set in a furnace, and a regulated proportion of compressed air is mixed with the oil as it enters the flues. Compressed air from an external source of supply is stored in a reservoir, from which it is distributed by a pipe having branches, controlled by valves, and leading to the oil pump, the oil reservoir, and the oil pipe to the flues. The gas generated in the flues is passed through a cooler, a scrubber, and a purifier on its way to the holder or main.—W. H. C.

Gas generator. W. H. Cone, Berlin, Ontario. Assignor to the Cone Gas Machine Co., Detroit, Mich. U.S. Pat. 830,883, Sept. 11, 1906.

The claim is for a gas generator, having a conical bottom to the "fire-pot" and a conical shaking grate superimposed on the bottom, and provided with a shaking handle. At the apex of the conical bottom there is a projecting cylindrical air-passage, or pipe, which is prolonged downwards, and communicates with an annular chamber into which air and steam can be introduced. The air-passage has a valve at the top, which is attached to a rod passing down the pipe, and which is raised or lowered by another rod, extending horizontally beyond the casing of the generator. At about the level of the top of the "fire-pot" is another annular air or steam chamber, having several lateral openings into the generator. A ring, with a series of holes corresponding to the above-mentioned openings, and which is situated in the annular chamber, can be adjusted by a handle from outside, so as to entirely or partially close the openings into the generator.—W. H. C.

Gas producer. W. E. Cook, Berlin, Canada, Assignor to the Cook Gas Machine Co., Detroit, Mich. U.S. Pat. 830,694, Sept. 11, 1906.

A "WATER-SECTION," with a central opening, and which is pierced by several gas-flues, is superimposed on the generator described in the preceding abstract. The "water-section" is covered by a dome, with a corresponding central opening, and is provided with water- and air-supply pipes and a valve-controlled vapour pipe, which passes down through the brickwork of the wall of the generator to the annular chamber surrounding the "fire-pot."—W. H. C.

Gas producer. G. Campion and M. Wyant, Anderson, Ind. U.S. Pat. 830,968, Sept. 11, 1906.

THE producer has a cylindrical upper portion, a conical intermediate portion, and a cylindrical lower portion, and is supported on "arc-form" piers over a central "water-bosh." It is provided with four ribbed, angular, inclined grates supported on pillars projecting upwards from the "water-bosh" and on ledges formed on the interior of the lower cylindrical wall of the producer. Four charging hoppers are arranged on the top of the producer, each one being placed immediately over one of the four grates.—W. H. C.

Coal gas; Process of treating —— for extracting tar, water, and ammonia. W. Feld, Hönningen on Rhine, Germany. U.S. Pat. 830,983, Sept. 11, 1906.

SEE Fr. Pat. 360,528 of 1905; this J., 1906, 529.—T. F. B.

Storage vessels for liquid gases; Appliance for —— [to prevent freezing on discharge]. L. von Orth, Berlin, Assignor to Deutsche Schiffs Feuerlöschges., m.b.H., Bremen, Germany. U.S. Pat. 830,248, Sept. 4, 1906.

SEE Eng. Pat. 4694 of 1904; this J., 1904, 483.—T. F. B.

Filament; [Electric] Incandescent lamp ——, and method of making the same. J. M. Canello, Paris. U.S. Pat. 829,568, Aug. 28, 1906.

A FILAMENT for incandescence lamps having a core composed of the oxide of a rare earth, a continuous conducting coating of metal, and an outer coating of oxide, is made by incinerating a combustible thread impregnated with a rare earth compound, rendering it conducting by the application of a metallic deposit, heating it by passing an electric current through, and exposing the heated thread to reducing gases and to vapours of compounds of the ruthenium group. The filament is then subjected to the action of a thorium compound of acetylacetone, to form an outer coating of thorium oxide.—R. L.

FRENCH PATENTS.

Fuel; Artificial ——, and method of making the same. J. W. Leadbeater. Fr. Pat. 364,305, March 16, 1906.

THE briquettes are prepared with the aid of an enriching material composed of petroleum (approximately 56 per cent.), sawdust, peat, or other granular absorbent (26 per cent.), tar, pitch, resin, or wood tar (8 per cent.), and dry slaked lime (10 per cent.). The bulk of the sawdust is intimately mixed with the petroleum, the pitch, lime, and remainder of the sawdust being gradually added in succession, and incorporated in the mixer. The product is mixed with the substance forming the basis of the fuel; and when the whole is to be made into briquettes, a further proportion of the enriching material is incorporated after the fuel has passed through the heating apparatus, and before it reaches the moulds.—C. S.

Briquettes; Binding agent for ——. G. A. Besnard. Fr. Pat. 364,341, March 17, 1906.

[illegible] petroleum, vegetable gum, [illegible] are dissolved in [illegible] water, and [illegible] dust, lime, [illegible] the mixture [illegible] of [illegible] gas.

"Bûches de Noël" (Christmas logs); Manufacture of combustible bodies, known as ——. Bataille & Co. Fr. Pat. 365,393, April 11, 1906.

IN order to make the combustible bodies, known as "Bûches de Noël" (Christmas logs), sufficiently porous to avoid the production of carbon monoxide during the process of combustion, sodium bicarbonate or other body susceptible of partial or complete transformation into gas at the moment of carbonizing the combustible in a closed vessel, is added to the other ingredients in the course of the manufacture.—W. C. H.

Glue or size, and process of making the same. M. Bamiat. Fr. Pat. 365,285, April 14, 1906. XIV., page 962.

Gas retorts of refractory clay. T. Jerratsch. Fr. Pat. 365,162, April 11, 1906. Under Int. Conv., July 20, 1905.

A RETORT for the manufacture of illuminating gas has its extreme ends made as separate pieces. Thus the central part of the retort which is most exposed to the heat can be replaced separately, without replacing the end parts. These ends, which carry the mouthpieces, may have a rectangular or polygonal section where they are fixed in the masonry of the furnace, whilst at the other ends they have openings of the same shape as the cross-section of the central part of the retort. The body of the retort is thus relieved of the weight of the casings at the ends.—R. L.

Gas from rocks and other carbonated minerals; Process for the extraction of lighting and heating ——. S. and A. Seigle. Fr. Pat. 361,546, June 9, 1906.

POWDERED carbonates of lime or magnesia are mixed with powdered coal, or these ingredients may be compressed into balls with the addition of an agglomerant, and maintained at a suitable temperature in distillation retorts, or in producers constructed for the purpose, in such a way that in proportion as the carbon dioxide is liberated, it can take up a fresh equivalent of carbon, or in certain cases that arise, a fresh equivalent of hydrogen, under the action of hydrocarbon vapours or of hydrocarbons or powder of incandescent carbon, with or without the intervention of steam, in order to yield a combustible gas.—W. C. H.

Water-gas; Manufacture of ——. L. J. Terneden and J. M. Muller. Fr. Pat. 364,661, March 19, 1906.

THE improvements in the manufacture of water-gas, claimed are: The "blowing up" in parallel is so effected that the current or blast traverses a number of producers, at least equal to two, and the gasification in two or more producers arranged in series; the producers are worked in such a way that the gasification goes on only up to a certain height above the bottom of the products to be gasified, a height at which the gas is also drawn off; the producer is supplied with a circular gas collector, mounted either in the masonry of the producer, or outside it, in which case the gas collector can be advantageously cooled by water. The objects of these arrangements are to give uniformity to the production of gas, to diminish the amount of carbon dioxide in the gas, and to prevent the formation of clinker on the bars.—W. C. H.

Air and gas; Production of a mixture of —— for lighting purposes. Soc. par Actions pour l'éclairage [illegible]. Fr. Pat. 364,840, April 2, 1906. Under Int. Conv., April 4, 1905.

IN an apparatus for the production of mixtures of gas and air for lighting purposes, the orifices admitting gas and air into the aspiration chamber are provided with shutters, whereby their size can be varied, this regulation being controlled by a governor which is in direct communication with the aspiration chamber, and [illegible] regulated by the pressure prevailing in it. [illegible]

Gas; Combination of a generator for poor —— with a steam-generator. A. Guiot. Fr. Pat. 364,841, April 2, 1906.

The fire-box of a steam generator or boiler is transformed into a gas producer by closing it in, and burning the fuel with artificial draught. The poor gases produced serve at the same time for heating the boiler, and supplying motive power to a gas motor.—R. L.

Combustibles; Gasifying and superheating liquid ——. C. Heinrichsdorff. Fr. Pat. 364,891, April 4, 1906.

Liquid combustibles are gasified and superheated in an apparatus consisting of two concentric tubes, the space between them being divided into an upper and a lower chamber. The liquid enters the lower annular chamber, and passes through orifices into the inner tube, which, in its lower part, is filled with a granular filtering material such as sand, to retain residues of carbonisation. The liquid is then gasified, and passed through perforations in the upper half of the inner tube into the upper annular space, which is open at the end. The jacket spaces being filled with liquid and gas respectively, the heating of the bulk of liquid and the superheating of the vapours takes place more uniformly than by applying the heat direct to a single tube.—R. L.

Gas producer. E. Lorin. Fr. Pat. 364,893, April 4, 1906.

In a generator for the production of heating or illuminating gas, the blast-pipes supplying the necessary air are movable, so that they may penetrate the incandescent mass to varying depths, according to the quality of fuel burned. They are surrounded by water pipes, which cool and protect the air blowers from the fire. The steam generated can be blown into the generator together with the air. A movable dust chamber is provided in the exit opening of the generator, and the gases produced are conveyed through a tar separator, washer, and purifier. —R. L.

Gas producers for poor gases. J. L. M. Fornas. Fr. Pat. 364,970, April 5, 1906.

The poor gas formed is collected in an annular chamber round the base of the producer. This chamber is provided with a water-jacket, in which the steam required for the gas producer is generated, and which incidentally cools the lower part of the producer. The grate is protected by a layer of ashes.—R. L.

Gas; Process for the production of ——. Deutsche Bauke-Gas. Ges. m.b.H. Fr. Pat. 365,334, April 17, 1906.

According to this process for the production of power gas, the producer is worked at a comparatively low temperature, and the fire zone is maintained too shallow to yield a good water- or producer-gas, or mixture of the two, but the quality of the gas is raised to a suitable value by blowing into the reducing zone carburetted bodies, either as powder, or as vapour or gas, suitably mixed with air or steam. In cases where bituminous coals are used, the products of distillation, tar, &c., drawn from the upper part of the producer, are re-introduced into the fire zone, which is kept shallow to ensure regular working of the gas-producing process, after previous admixture with air or steam.—W. C. H.

Suction Gas Producer. Deutsche Bauke-Gas. Ges. m.b.H. Fr. Pat. 365,364, April 18, 1906.

The producer consists of an outer casing from near the top of which the gas is drawn off to the engine. Within this casing is another which extends downwards nearly as far as the grate bars; fuel is fed into the top of this inner casing, and there undergoes a process of distillation, the products of which are drawn off near the top and carried down by a pipe, provided with an injector, capable also of introducing steam or a mixture of steam and air, and forced into the bed of incandescent fuel on the grate bars. Near the lower end, and nearly filling the inner casing, is a hollow inverted cone, which can be raised, lowered, or screwed by suitable mechanism from without. The object of this cone is to increase by its movement the regular distribution of the air-supply, and thereby distillation, and as the cone is hollow and open at the bottom, the distillation is favoured by the heat radiated from the reducing zone of the producer, which reaches the combustible through the wall of the cone. (See also Fr. Pat. 363,348, Feb. 16, 1906; this J., 1906, 342.)—W. C. H.

Gases or vapours; Apparatus for the elimination of impurities from ——. R. Scheibe. Fr. Pat. 365,065, April 7, 1906.

The invention consists essentially in the introduction of a rotary fan or blower into the main or flue through which the gases or vapours pass from the generators to the place of use. The rotation is effected either by the passage of the gas itself, or by external mechanism, and the centrifugal force throws the impurities either through a perforated casing, or directly on to the walls of the chamber in which the fan works, and from which they are removed. —W. H. C.

Gas calorimeter. H. L. Doherty. Fr. Pat. 365,214, April 13, 1906.

See Eng. Pat. 8866 of 1906; this J., 1906, 633.—T. F. B.

Incandescence mantles; Manufacture of ——. H. L. Cossard. Fr. Pat. 364,754, March 30, 1906.

A mixture of thorium nitrate, 1000 grms.; cerium nitrate, 10 grms.; and beryllium nitrate, 2·5 grms., is placed in a flask and treated with ammonia gas obtained from "the aqueous solution of ammonia liquefying at −40° under atmospheric pressure." The product is then "hydrated," and, after washing, the "solution" of oxide is used for impregnating a fabric woven from cotton and natural silk. This is dried rapidly at 50°—60° C., and then burned off.—H. B.

Incandescence mantle for automatic ignition. Fischel und Pick, and G. Imiela. Fr. Pat. 364,839, April 2, 1906. Under Int. Conv., Aug. 2, 1905.

An igniting body, consisting of alumina and platinum black, is applied to the interior of the mantle at not more than 3 cm. above the mouth of the burner, and is connected to several igniting strips or lines formed from ammonium chloroplatinate or the like.—H. B.

Incandescence mantles for gas burners. J. E. T. Woods and M. von Schmidt. Fr. Pat. 365,341, April 17, 1906. Under Int. Conv., April 17, 1905.

See Eng. Pat. 8162 of 1905; this J., 1906, 213.—T. F. B.

Incandescence lamps; Process of increasing the electric resistance of certain metals, especially those used for glow-bodies of ——. H. Kuzel. Fr. Pat. 364,613, March 27, 1906. Under Int. Conv., July 26, 1905.

The metallic glow-body, consisting of chromium, manganese, molybdenum, uranium, tungsten, vanadium, tantalum, niobium, titanium, thorium, zirconium, platinum, osmium, or iridium, whether in the colloidal or crystalline (wire-drawn) state, is heated to whiteness in an indifferent atmosphere whilst in contact with small quantities of boron, silicon, or carbon, or compounds capable of liberating these elements. The metal absorbs a certain amount of the boron, silicon, or carbon, whereby its resistance is increased. The boron, &c., may be applied in the gaseous form (as boron hydride, &c.), mixed with an inert gas, or as a liquid, in which the incandescent metal is immersed.—H. B.

Glow-bodies for electric lighting; Manufacture of ——. Siemens und Halske A.-G. Fr. Pat. 364,925, April 5, 1906. Under Int. Conv., April 8, 1905.

A wire, of rolled or wire-drawn metal, is transformed from the surface inwards into a chemical compound of increased electrical resistance, by causing the wire to absorb substances capable of forming chemical compounds with it. For example, a wire of tantalum is stretched, upon a support, such as is used in a tantalum lamp, and is immersed in a liquid capable of being carbonised, such as petroleum or benzol, whilst heated to incandescence by means of an electric current. Carbide of tantalum is

formed progressively from the surface towards the centre of the wire, and the treatment is stopped when the desired resistance is reached.—H. B.

Incandescence electric lamps with metallic filaments; Manufacture of ——. Deutsche Gasglühlicht. A.-G. (Auergesellsch.). Fr. Pat. 365,185, April 12, 1906.

The breaking of the filament in a metallic-filament lamp seems to be due to the fritting of the filament on to its supports, owing to the deposition at such points of the metallic particles liberated by the disintegrating action of the current. To obviate this defect, the patentees provide the lamp internally beforehand with surfaces carrying a slight metallic deposit, which offers numerous points on which the pulverised metal may collect, instead of upon the filament. To provide such surfaces, for example, the bulb, before it is sealed, is filled with hydrogen at a pressure of a few millimetres, and the electric current is passed through the filament. In a few minutes, disintegration of the filament substance occurs, and a deposit is formed on the various surfaces inside the lamp. If the supports for the filament are white, the formation of the deposit is indicated by the appearance of a greyish colour. The hydrogen is then removed from the bulb.
—H. B.

Distilling apparatus [*for petroleum, &c.*]. Dampfkessel- und Gasometerfabr. vorm. A. Wilcke and Co. Fr. Pat. 363,993, March 9, 1906. Under Int. Conv., July 29, 1905.

A still is connected with a column and a condenser by two pipes, each of which is fitted with a tap, to enable the vapours liberated in the still to be diverted at will into the column or the condenser, according as the vapours are furnished by substances of low or high boiling point.
—C. S.

Petroleum; Process for extracting —— *from outcrops of bituminous rock.* K. Rudeloff. Fr. Pat. 364,431, March 30, 1906. Under Int. Conv., March 31, 1905.

Compressed [air] into the outcrop is mixed with fuel, which is also introduced into the [bituminous] rock. The outcrop being covered up, the impervious material is pierced [to prevent loss by evaporation], the fuel is ignited, and the petroleum which distils out is collected in pipes or gutters (previously arranged within and upon the surface of the rock). Means are provided for admitting air to the burning fuel, and also for pumping or conveying the oil to the surface.—C. S.

Distilling hydrocarbonaceous substances; Process and apparatus for ——. American Eduction Co. Fr. Pat. 365,168, April 12, 1906.

See U.S. Pat. 821,323 of 1906; this J., 1906, 584.—T. F. B.

Lubricating oil which emits no odour or even has an agreeable odour on burning. A. Haenflein and L. Kornfeld. Fr. Pat. 365,335, April 17, 1906. XII., page 933.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 880.)

Nitrophenolsulphonic acids; Contribution to the knowledge of ——. R. Gnehm and O. Knecht. J. prakt. Chem., 1906, **74**, 92—111.

o-Nitroanisol-p-sulphonic acid is obtained quantitatively by mixing molecular proportions of *o*-nitroanisol and chlorosulphonic acid at the ordinary temperature. The new acid dissolves in anhydrous ethyl acetate, and very readily in water, crystallising from the latter in lustrous transparent plates. By treatment with phosphorus pentachloride, *o*-nitroanisolsulphonchloride, m. pt. 66° C., is prepared, and this substance yields a sulphonamide m. pt. 146·3° C., which is identical with the product obtained by Franklin (see Amer. Chem. J., 1896, **19**, 463) by the nitration of anisol-*p*-sulphonic acid. The sulphonic group in the above acid must, therefore, be in the *p*-position. By reduction of the nitrosulphonic acid with tin and hydrochloric acid, *o*-anisidine-*p*-sulphonic acid is obtained. This easily soluble substance when diazotised and combined with β-naphthol in alkaline solution produces a bluish-red dyestuff. By complete reduction with tin and hydrochloric acid the sulphonchloride is converted into *p*-methoxy-*m*-aminothiophenolhydrochloride ($ClNH_3$)(OCH_3).C_6H_3.SH[OCH_3:NH_3Cl:SH = 1:2:4], which crystallises in odourless white needles, m.pt. 230°—235° C. This hydrochloride is an unstable substance which has a great tendency to go over by oxidation into the hydrochloride of the corresponding disulphide. The latter substance, however, is readily diazotised, and forms a yellow diazonium solution, which combines with β-naphthol in alkaline solution to form a crimson azo dyestuff.

The authors attempted to prepare sulphurised thiazines by condensing *p*-methoxy-*m*-aminothiophenolhydrochloride with dimethyl-*p*-phenylenediaminethiosulphonic acid. A very impure reaction product was obtained, from which a homogeneous substance could not be isolated. The blue coppery powder finally prepared by partial purification of the crude mass appeared to be intermediate between a thiazine and a sulphide dyestuff. It possesses a great affinity for tannin-mordanted cotton, on which it is stated to produce bright sky-blue shades of great fastness to washing. On the other hand, it does not form a hydrochloride, and if dyed on untreated cotton with the addition of sodium sulphide, fairly deep but not very fast blue shades are obtained after oxidation in the air.
—F. L.

Brazilin and Haematoxylin. J. Herzig and J. Pollack. Monatsh. Chem., 1906, **27**, 763—771.

In referring to the different formulæ which have been proposed for brazilin, the authors mention, that in view of their observations on the behaviour of tetraethyl-brazilone and tetramethylhæmatoxylin with hydroxylamine and phenylhydrazine, they prefer to adopt a formula of structure [illegible]

with acetic anhydride, sodium acetate, and zinc dust, a reduced acetyl compound, $C_{23}H_{19}N_3O_3(OCH_3)_4$, is obtained, analogous with the substance prepared in a similar manner from trimethylbrasilone. It crystallises from alcohol in white needles melting at 188°—192° C. The transformation product obtained by treating tetramethylhæmatoxylone with cold sulphuric acid is described. It contains a highly acid hydroxyl group, does not react with hydroxylamine and phenylhydrazine, and yields a methyl ether melting at 99°—101° C. which can be readily hydrolysed with alkali. The compounds obtained by nitrating the transformation products of trimethylbrasilone and tetramethylhæmatoxylone are described.—D. B.

Saponarin, a new glucoside, coloured blue with iodine. G. Barger. XX., page 951

English Patents.

Indigo; Manufacture of —— from phenylglycine or its derivatives. A. G. Bloxam, London. From F. Becker, Friedenau, Germany. Eng. Pat. 19,353, Sept. 25, 1905.

It is found that the formation of products, easily converted into indigo, by the action of sodium amide and sodium cyanide on phenylglycine or its derivatives, is primarily due to the presence of disodium cyanamide. The present process consists, therefore, in introducing equal weights of disodium cyanamide and phenylglycine into a crucible heated to 300°—400° C., treating the mass, when cool, with water, and blowing air through the solution. The yield of indigo is stated to be nearly quantitative.—T.F.B.

Indophenol [for sulphide dyestuffs]; Manufacture of an ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 27,000, Dec. 27, 1905.

In the preparation of the indophenol, $NH_2.C_6H_4.N:C_6H_4:O$, by the joint oxidation of paraphenylenediamine and phenol, it is claimed that good yields are obtained by using certain insoluble metal peroxides, *e.g.*, lead peroxide or manganese dioxide, as oxidising agents, especially in presence of a substance, such as disodium hydrogen phosphate, which facilitates the oxidising action of the peroxide. For example, 11 parts of paraphenylenediamine and 10 parts of phenol are dissolved in 1500—2000 parts of water, and the solution is treated, with agitation, with a paste containing 48 parts of lead peroxide, 50 parts of disodium hydrogen phosphate, and 35 parts of sodium bicarbonate; the last-named substance is for the purpose of rendering the mixture faintly alkaline. The precipitate is filtered off, and the indophenol extracted from it by alcohol or hot water; the resulting solution may be used directly in the manufacture of sulphide dyestuffs.—A. S.

Colour lakes [from azo dyestuffs]; Manufacture of ——. O. Imray. From Meister, Lucius, und Brüning. Eng. Pat. 27,252, Dec. 30, 1905. XIII*A*., page 939.

Azo dyestuffs; Manufacture of yellow ——. O. Imray, London. From Farbw. vorm. Meister, Lucius, und Brüning, Hoechst a/Main, Germany. Eng. Pat. 2622, Feb. 2, 1906.

Yellow dyestuffs, stated to be very fast to light, are produced by combining diazotised *m*-xylidine-*o*-sulphonic acid $[(CH_3)_2:NH_2:SO_3H = 1:3:4:5]$ with 1-sulphoaryl-3-methyl-5-pyrazolones or with 1-sulphoaryl-5-pyrazolone-3-carboxylic acids. The same compounds are obtained by sulphonating the reaction products of diazotised *m*-xylidine-*o*-sulphonic acid with 1-aryl-3-methyl-5-pyrazolones or 1-aryl-5-pyrazolone-3-carboxylic acids.—H. L.

Dyestuff; Manufacture of an [azo] ——, and colour lakes made therefrom. Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst a/ Main, Germany. Eng. Pat. 9989, April 28, 1906. Under Int. Conv., May 18, 1905.

Diaminoxylylmethanes, obtained by condensing xylidine with formaldehyde, are diazotised with 2 mols. of nitrous acid and combined with 2 mols. of "2.3 acid" (naphthol-sulphonic acid $OH:SO_3H = 1:2:4$-naphthol-3-sulphonic acid). The resulting dyestuff is stated to be particularly adapted, on the preparation of lakes in the usual manner, these are said to be absolutely fast to water, and to possess very pure, brilliant blue-red shades. (See Eng. Pat. 15,386 of 1892; this J., 1893, 754.)—T. F. B.

Naphthalene derivatives; Manufacture of new colouring matters [Azo dyestuffs] from ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 7287, March 26, 1906.

Azo dyestuffs giving red to violet shades, fast to light, are obtained by combining monoalkyl-ethers of 1.4-dihydroxynaphthalene with sulphonated diazo- and tetrazo-compounds of the benzene and naphthalene series. For instance, the diazo solution from 17·3 parts of metanilic acid is run into a solution containing 17·4 parts of the sodium salt of the monomethyl-ether of 1.4-dihydroxynaphthalene, together with sufficient sodium carbonate to render the solution alkaline, the mixture being stirred, and cooled to 0° C. The dyestuff is recovered by salting out. It dyes wool very level bluish-red shades.—A. S.

Naphthalene derivatives; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabr., Ludwigshafen, Germany. Eng. Pat. 7287*A*, March 26, 1906.

Monoalkylethers of 1.4-dihydroxynaphthalene are prepared by heating 1.4-dihydroxynaphthalene with alcohol and a mineral acid.—H. L.

Thioindoxylcarboxylic acid; Manufacture of a sulphur-containing red colouring matter from ——, and from Thioindoxyl. Kalle und Co., Biebrich on Rhine, Germany. Eng. Pat. 14,057, June 19, 1906. Under Int. Conv., Dec. 22, 1905.

Thioindoxylcarboxylic acid or thioindoxyl are converted into the corresponding red dyestuff, which contains sulphur, by heating with sulphur, sulphuretted hydrogen being evolved.—H. L.

United States Patent.

Ortho-oxymonoazo dye [Azo dyestuff], and process of making same ——. K. Schirmacher, F. Schmidt, C. Pretzell, and W. Schumacher, Assignors to Farbw. vorm. Meister, Lucius, und Brüning, Hoechst on the Maine, Germany. U.S. Pat. 827,468, July 31, 1906.

The process is claimed for preparing *o*-oxymonoazo dyestuffs from chromotropic acid and diazotised *o*-amino-oxybenzene derivatives containing no sulpho-group, which consists in causing these bodies to act upon each other in presence of hydroxides of elements forming "the five middle members of the second group of the periodic system." The bluish-red dyestuff formed by the combination above referred to is claimed as a new product (see this J., 1906, 471).—H. L.

French Patents.

Phenylnaphthimidazole; Process of making aminohydroxylated derivatives of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 361,543, June 8, 1905.

See Eng. Pat. 11,759 of 1905; this J., 1906, 215.—T. F. B.

Dyestuffs; Process for making new monoazo ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 365,040, April 9, 1906.

Aminosulphonic acids of the benzene or naphthalene series are diazotised, and combined with 1.4-dihydro-2.6-phenylenediamine; the resulting dyestuffs dye wool from acid baths in yellow to orange shades, of satisfactory fastness to light and acids.—T. F. B.

Dyestuffs; Production of azo —— susceptible to shrinking on the fibre. Soc. pour l'Industrie Chimique à Bâle. Second Addition, dated June 19, 1905, to Fr. Pat. 355,188, Jan. 4, 1905.

The presence of certain organic compounds, such as glycerol, glycerol, invidine, and sorbine, has been found to

increases greatly the power of combination of *o*-diazonaphthylamine-sulphonic acids with other components. When alcohol is employed, diazotisation may also take place in alcoholic suspension. 24 kilos. of 1.2.4-aminonaphtholsulphonic acid, previously acetylated in the hydroxyl group, as described in the principal patent (this J., 1905, 849), are dissolved by means of 7 kilos. of sodium nitrite, the acetyl group is eliminated (either by long standing, or by neutralising with sodium hydroxide), and the solution is added to a solution of 16 kilos. of 1.5-dihydroxynaphthalene, 25 kilos. of caustic soda solution, 30° B., and 100 kilos. of pyridine; the formation of the dyestuff commences immediately; after two hours the product is diluted, and the dyestuff precipitated by acetic acid or a mineral acid. It dyes wool in violet shades, transformed on after-chroming into very fast greenish-black shades. The combination of similar diazonium compounds with α-naphthol, β-naphthol, 1.8-dihydroxynaphthalene, 1.5-naphtholsulphonic acid, and 1.6-aminonaphthol is also described. (See also this J., 1905, 1168.)—T. F. B.

Indigo; Process for making ——. A. Rahtjen. Fr. Pat. 365,109, Feb. 17, 1906. Under Int. Conv., March 6, 1905.

INDIGO can be formed quantitatively from α-isatinanilide by treatment with hydrogen sulphide, in neutral or alkaline suspension, at temperatures between 25° and 70° C. At lower temperatures indigo is not formed directly, but the product (probably α-thioisatin) can be readily converted into indigo. Hydrogen sulphide may, for example, be passed into a solution of 10 parts of α-isatinanilide in 30—40 parts of alcohol, at the ordinary temperature, until the solution is decolorised; after dilution, the indigo is precipitated by means of air or other oxidising agent, alone or in presence of alkali, or by addition of alkalis or acids. Indigo may be produced directly by passing hydrogen sulphide into an aqueous suspension of α-isatinanilide at a temperature of 50° C. The sulphur can be removed from the indigo by any suitable method. —T. F. B.

1.8-Arylaminonaphtholsulphonic acids; Production of ——, *and of azo dyestuffs derived therefrom.* Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 364,004, March 9, 1906. Under Int. Conv., April 26, 1905.

THE preparation is claimed of 1.8-arylaminonaphtholsulphonic acids by heating 1.8-aminonaphtholsulphonic acids or their salts with an aromatic base in the presence of water, and of azo dyestuffs by combining these substances with diazo compounds. Arylation may be carried out with or without the addition of a condensing agent or of a salt of the aromatic amine. Example: 341 parts of 1.8-aminonaphthol-3.6-disulphonic acid, 200 parts of aniline, and 1000 parts of water are heated to 140° C. for 48 hours. The mass is then made alkaline, and the excess of aniline driven off with steam. After neutralising, 1.8-phenylaminonaphthol-3.6-disulphonic acid is precipitated with salt in the form of white needles. The shades of a number of the combinations made with the above and other 1.8-arylaminonaphtholsulphonic acids by the process claimed are shown in the following table:—

Dyestuff.		Shade produced on wool.
p-nitraniline α-naphthylamine β-naphthylamine diphenylaniline *o*-anisidine aminoazobenzene	+ 1.8-phenylaminonaphthol-3.6-disulphonic acid	Black Blue black Violet black Violet black. Violet Black
p-nitraniline α-naphthylamine aniline	+ 1.8-*p*-tolylaminonaphthol-3.6-disulphonic acid	Black Blue black Violet black
α-naphthylamine 1.4-nitronaphthylamine-8-sulphonic acid [illegible]	+ 1.8-phenylaminonaphthol-4.6-disulphonic acid	Violet Blue black Violet-black
[illegible]	[illegible]	Blue black
[illegible]	[illegible]	Black Violet
[illegible]	[illegible]	Black Violet

Anthracene series; Production of dyestuffs of the ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 364,219, March 13, 1906. Under Int. Conv., June 13, 1905.

DYESTUFFS of the anthracene series which dye cotton from an alkaline hydrosulphite vat, are produced by heating α-aminoanthraquinones with alkali phenolates or with mixtures of caustic alkalis and phenols, with or without the addition of oxidising agents. The product thus obtained from α-aminoanthraquinone yields, it is stated, blue shades; that from 1.4-diaminoanthraquinone, green shades; and those obtained from 1.5- and 1.8-diaminoanthraquinone respectively, yield bluish-green shades. —H. L.

Azo dyestuffs; Production of new ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 364,406, March 19, 1906. Under Int. Conv., Oct. 23, 1905.

NEW azo dyestuffs are prepared by combining the tetrazo-compound of the di-*p*-aminophenyl ether of glycol, $NH_2.C_6H_4.O.CH_2.CH_2.O.C_6H_4.NH_2$, with two molecules of either 2.5-aminonaphthol-7-mono- or 1.7-disulphonic acid, or substitution products thereof, or with one molecule of these substances and another molecule of some other suitable compound. The products obtained are stated to possess excellent affinity for unmordanted cotton, producing bright red shades fast to acids. A table is given in which twenty-one such combinations are described.—H. L.

Anthracene series; Production of derivatives of the —— [*Anthracene dyestuffs.*] Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 365,305, April 14, 1906. Under Int. Conv., Oct. 23, 1905.

BY condensing alizarin or its derivatives with *o*-diamino anthraquinones, hydro-azines are obtained, which form "vats" when treated with alkaline reducing agents, dyeing cotton blue, green, and brown shades. Twenty kilos. of alizarin, 20 kilos. of 1.2-diaminoanthraquinone, 20 kilos. of boric acid, and 200 kilos. of phenol are heated to boiling for 16 to 20 hours, and the product is poured into water, and purified by washing with hot water and hot pyridine; a blue "vat" is obtained from this product, as also from those from 1.2- or 2.3-diamino anthraquinone and purpurin. The products from 1.2- or 2.3-diaminoanthraquinone and purpurin-α-sulphonic acid give bluish-green vats, those from 2.3-diaminoanthraquinone and Alizarin Blue or Alizarin Bordeaux, green vats, whilst those from 2.3-diaminoanthraquinone and alizarin or β-nitroalizarin form brown vats. (See also this J., 1902, 42; 1903, 1192; 1904, 1626, 1209, 1210; 1906, 1167.)—T. F. B.

Dyestuffs; Production of new mordant-dyeing azo ——. Farbenfabr. vorm. F. Bayer und Co., Fr. Pat. 365,415, April 19, 1906. Under Int. Conv., Dec. 20, 1905.

5-NITRO-4-CHLORO-2-AMINOPHENOL, obtained together with 6-nitro-4-chloro-2-aminophenol, by nitrating 4-chloro-2-aminophenol, or its ethenyl derivative, is diazotised and combined with the sulphonic acids of the naphthol-aminonaphthols, dihydroxynaphthalenes, or their derivatives. The dyeings on wool from acid baths are reddish shades of red, converted, by subsequent treatment with bichromate, into blue, green, and black shades.—T. F. B.

Indigo; Preparation of an [illegible] —— [illegible]. Fr. Ext. 364,681, March 19, 1906.

[illegible]

of caustic soda of 38° B. for 30—45 minutes at 80° C., and claims that after precipitation with dilute sulphuric acid he obtains a "new variety" of indigo. This substance is said to be practically soluble in water made slightly alkaline with sodium carbonate or ammonia, and to produce shades 50 per cent. deeper than ordinary indigo of the same strength under equal conditions of dyeing.—H. L.

Dyestuff suitable for the preparation of lakes; Process for making an [azo] ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 364,807, March 31, 1906. Under Int. Conv., May 18, 1905.

See Eng. Pat. 9989 of 1906; preceding these.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

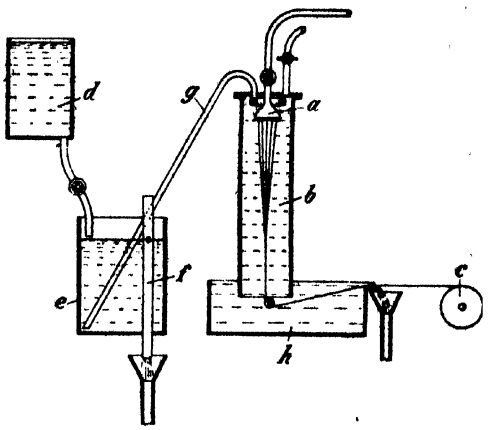
(*Continued from page* 881.)

Sodium sulphide-formaldehyde; Reserves under Aniline Black by means of ——. E. Trepka. Rev. Gen. Mat.-Col., 1906, **10**, 257—258.

The author proposes to produce coloured reserves under Aniline Black by means of basic dyestuffs fixed with zinc sulphide. (See H. Schmidt, Bull. Rouen, 1883, 291.) The dyestuff is printed together with a soluble zinc salt and sodium sulphide-formaldehyde. On steaming, zinc sulphide is formed, and is precipitated on the fibre, together with the dyestuff. The sodium sulphide-formaldehyde is prepared as a thin paste by adding 2000 grms. of 40 per cent. formaldehyde to a solution of 1000 grms. of sodium sulphide in 4 litres of water at 40° C. After 24 hours this mixture is strained through a cloth, and is then ready for use. The following are the recipes for the reserves which are printed on cloth prepared with aniline salt, sodium chlorate, and potassium ferrocyanide in the usual way for Aniline Black.

	Red.	Pink.	Yellow.	Olive.	Dark blue.	Sky blue.
Thickening S.	400	400	400	400	400	400
Zinc sulphate cryst.	100	100	100	100	100	100
Rhodamine 6G. ...	12	10	—	—	—	—
Thioflavine	12	—	—	—	—	—
Safranine	12	—	—	—	—	—
Auramine	—	—	30	35	—	—
Methylene Blue....	—	—	—	5	30	10
Water	104	240	100	100	220	240
Methyl alcohol	100	—	70	80	—	—
Sod. sulphide-form.	200	200	200	200	200	200
Sod. acetate	—	—	50	30	—	—
Magnesium acetate, 24° B.	60	50	50	50	50	50
	1000	1000	1000	1000	1000	1000

Thickening S is made up of 320 parts of dextrin, 500 parts of starch, 100 parts of water, 480 parts of potassium sulphite 40° B, 100 parts of glycerol, and 100 parts of olive oil. After printing, the goods are steamed for four to five minutes, chromed, rinsed, and soaped. The colours are stated to be as fast to washing, but scarcely so bright as those obtained with zinc-white and albumin preparations; but the mixtures can be much better printed as they are free from insoluble substances.—H. L.



English Patents.

Silk, artificial; Process for the manufacture of ——. G. Gerrard, Saint-Etienne, France. Eng. Pat. 6160, March 14, 1906.

See Fr. Pat. 364,494 of 1906; this J., 1906, 1196.—T. F. B.

Artificial silk; Improved apparatus for the manufacture of ——. E. Thiele, Brussels. Eng. Pat. 16,078, July 16, 1906. Under Int. Conv., Oct. 23, 1905.

A new apparatus for spinning artificial silk is described (see figure). The spinning solution enters in thread form into the spinning vessel, *b*, through a rose or nozzle, *a*, and after passing through is wound upon a drum, *c*. The precipitation liquor is allowed to flow from the main reservoir, *d*, into the open auxiliary tank, *e*, in which the level of liquid is kept constant by means of an adjustable overflow pipe, *f*. It is conveyed by a pipe, *g*, into the spinning vessel, *b*, from which it flows away into the trough, *h*. The spinning vessel is closed at the top and

open at the bottom, so that the whole apparatus actually represents an upright siphon filled with precipitation liquor, of which one leg is formed by the spinning vessel, and the other by the tube, *g*. By this arrangement the auxiliary tank, *e*, is at a lower level than the spinning vessel, so that the fluid column in *b* is freed from the pressure it receives in the apparatus where the tank is above the spinning vessel. In the figure the level of liquid in *e* is higher than in the trough, *h*, so that the precipitation liquor flows in the direction mentioned. On the other hand, by lowering the overflow pipe, *f*, sufficiently, the direction of the flow of liquid may be reversed. By these means, it is claimed, a steadily uniform "vacuum," adjustable without interruption of the continuity of spinning, may be obtained.—H. L.

Silk; Process for simultaneously ungumming and dyeing raw natural ——. J. G. Lorrain, London. From Gebrueder Schmid, Basle, Switzerland. Eng. Pat. 2350, Jan. 30, 1906.

One hundred kilos. of raw silk hanks are suspended within a vessel containing a solution of 33 kilos. of soap and 5 kilos. of a rhodamine dyestuff in 580 kilos of water, the silk not being in contact with either the solution or the walls of the vessel. The solution is then heated to the boiling point, the lather produced rising and enveloping the hanks. After from 20 to 50 minutes, the dyed hanks are removed, and washed in water, whereby the softened sericin (silk-gum) is completely or partly removed from the fibroin. The formation of lather may be accelerated by injecting air under pressure into the soap solution at or near the bottom of the vessel, and weighting substances may be added to the bath.—A. S.

Warps or hanks of yarn or other woven or felted fabrics or fibrous materials; Machinery for drying ——. A. N. Marr, Leeds. Eng. Pat. 19,296, Sept. 27, 1906.

This machine consists preferably of three chambers placed parallel to the movement of the material, the middle compartment being the drying chamber and the lateral

ches the fan chambers, through one of the latter may be dispensed with if desired. The fans, working in the fan chambers, draw the moist air from the drying chamber, and also circulate the air over a heating apparatus before it enters the drying chamber. "Races," or angle iron paths, are mounted at the top and bottom of the drying chamber, and rods or poles intermittently traverse the races; the material is passed alternately around the upper and lower series of rods, thus forming folds or festoons, in which the material passes over the upper rod and under the lower. A pair of horizontal endless chains in the upper portion of the drying chamber, and a pair in the lower portion, work intermittently over sprocket wheels mounted on shafts carried by fixed bearings at the ends of each of the races, and each chain is provided with projections for carrying along through the drying chamber the series of rods inserted in the loops of the material. Two pairs of vertical endless chains are placed at the feed end of the machine, and one pair at the delivery end, each chain being provided with projections, and arranged to intermittently reciprocate in pairs over sprocket wheels. These chains convey the rods, when free from the material, from the lower to the upper races, and *vice versâ*. The cycle of intermittent movements of the whole of the endless chains is controlled by suitable gearing. The rods are thus automatically arranged and inserted on the under and upper surfaces of the material for forming it into loops, the material is made to traverse the drying chamber, and the rods afterwards disengaged from the festoons, and returned into position for re-insertion at the feed end of the machine. —B. N.

Seaweeds; Treatment of certain —— for the production of a thickening suitable for calico printing and various other purposes. The Calico Printers' Association, Ltd., Manchester, and W. Warr, Stalybridge. Eng. Pat. 22,301, Nov. 1, 1905.

Irish moss or other seaweed (70 lb.) is treated with dilute hydrochloric acid (1 lb. of 30 per cent. acid) to remove the lime, washed, and boiled with water containing sodium carbonate (30 ozs.) or ammonia; the mucilage is freed from the fibrous residue, and bleached, 6 lb. of bleaching powder being sufficient; when sufficiently bleached, 10 lb. of sodium bisulphite, 70° Tw., are added, and 2 lb. of 22 per cent. ammonia solution. When cool, the mucilage forms a thick transparent jelly, which may be employed in calico printing and finishing, especially with basic dyestuffs dissolved in phenol or aniline.—T. F. B.

Formaldehyde-sulphoxylic acid; Manufacture of alkali salts of ——. [Discharges.] J. Rohner, Basle, Switzerland. Eng. Pat. 14,343, June 22, 1906.

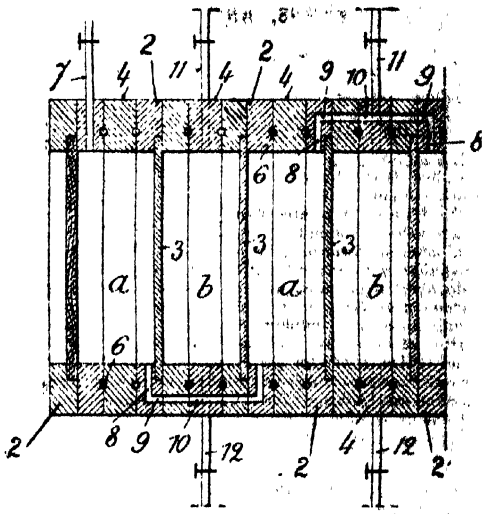
See Fr. Pat. 362,405 of 1906; this J., 1906, 692.—T. F. B.

United States Patent.

Cotton; [Electrolytic] Method of treating ——. G. D. Burton, Boston, Mass. U.S. Pat. 827,293, July 31, 1906.

Cotton is immersed in a bath in which wool has been degreased, and sodium carbonate or a mixture of one part of sodium chloride with two parts of sodium carbonate is added. An electric current is then passed through the whole. It is claimed that the wool grease is thus absorbed by the fibre, which becomes softened, and at the same time gains in tensile strength. Several methods for carrying out the process are described.—H. L.

French Patents.



Artificial silk works, &c.; Process for the recovery of the alcohol and ether contained in the air of ——. J. M. E. Dervin. First Addition, dated May 4, 1905, to Fr. Pat. 350,296, Nov. 8, 1904.

In the process described in the main patent (this J., 1906, 71) the air is passed through absorption towers containing sulphuric acid, and the acid is then distilled *in vacuo* in order to recover the ether. In the present addition, the process is modified: (1) by mixing the saturated sulphuric acid with one to two molecular proportions of water before distilling off the dissolved ether, to prevent loss of ether by conversion into ethylsulphuric acid; (2) the spinning operation is conducted in a closed chamber, with the primary object of limiting the volume of air which it is necessary to heat, and thus diminishing the amount of sulphuric acid necessary for absorption; (3) the dried air issuing from the towers is led back to the spinning chamber, and is thus forced to circulate continuously. In order to counteract the excessive dryness of the air with which it is brought into contact, hygroscopic substances, such as glycerol, or calcium or magnesium chloride, are added to the collodion, either before or after it has been drawn out into threads.—H. L.

Artificial silk; Tubular apparatus for forming gaseous coverings round the filaments formed in the manufacture of ——. H. E. A. Vittenet. Fr. Pat. 361,568, June 19, 1905.

See U.S. Pat. 828,155 of 1906; this J., 1906, 845.—T. F. B.

Dialyser [Purification of cuprammonium solutions in manufacture of artificial silk]. A. Lecœur. Fr. Pat. 365,099, April 11, 1906.

The apparatus, which is especially applicable to the process of purifying colloidal ammoniacal copper hydroxide, described in Fr. Pat. 362,986, of 1906 (this J., 1906, 903), has the form of an ordinary filter-press, as shown in the figure. The dialysing plates, 3, are formed of "asbestos-porcelain," and are carried in wooden frames, 2, between which are placed the distance frames, 4, the joints being made with rubber cord, as shown at 6. The liquid to be treated enters through the pipe, 7, into the first chamber, *a*, and circulates through the other chambers, *a*, *a*, by the channels, 8, 9, 10. The water enters through the pipes, 11, into each of the chambers, *b*, *b*, and leaves by the pipes, 12, carrying off the crystalloids in solution.—W. H. C.

Rabbit fur; Manufacture of an antiseptic product from —— to replace wool or down. J. Serre. Fr. Pat. 363,722, Feb. 22, 1906.

Rabbit fur is first beaten into a woolly or downy material, then treated with an "acid antiseptic" solution, consisting of 10 parts of ether and 90 parts of carbon bisulphide, and afterwards dried. It is claimed that treatment with this "acid antiseptic" solution renders the material stronger and more coherent, enables it to be spun, completely protects it against microbes and all kinds of insects, renders it a suitable substitute for antiseptic wadding, and makes it well adapted for the manufacture of all kinds of hygienic fabrics.—H. L.

Bleaching; Process of ——. E. Bingemann. First Addition, dated Feb. 10, 1906, to Fr. Pat. 362,513, April 7, 1906.

The process of bleaching described in the principal patent

(see this J., 1905, 1011) is modified by the introduction of a tier, in which a continuous boil can be given, so that the whole process of bleaching, from singeing to drying, can, it is claimed, be carried out in one operation.—H. T.

Bleaching and scouring of textile fabrics and vegetable and animal fibres; Electrolytic apparatus applicable to the ——. A. Dossonville. Fr. Pat. 363,866, March 3, 1906.

THE material receives a preliminary washing for the removal of impurities during its passage over a washing roller, and is then passed into the electrolytic bath between vertical plates of carbon insulated from each other, and supported on an insulated perforated plate. Two or more small windlasses, provided with blades, convey the material through the bath, the blades being cleaned by scrapers actuated by cams, in order to prevent the material from being entangled. The material, after leaving the electrolytic bath, is conveyed by travelling aprons between squeezing rollers, on to which streams of water are falling, in order to thoroughly wash it.—B. N.

Bleaching textile fibres, threads, and fabrics; Process for ——. H. Zeitschner. Fr. Pat. 364,797, March 31, 1906.

SEE Eng. Pat. 5296 of 1905; this J., 1906, 372.—T. F. B.

Shaded effects [on fabrics]; Process for obtaining ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,582, June 24, 1905.

SEE Eng. Pat. 10,195 of 1905; this J., 1906, 262.—T. F. B.

Drying installation [for textile materials]. E. Mertz. Fr. Pat. 364,914, April 4, 1906.

A DRYING-CHAMBER is placed over a heating-chamber, being separated from it by a floor formed of gratings. An air-flue, with a damper at each end, passes along each side of the floor of the drying chamber. By suitably arranging the dampers, a current of fresh air is forced by a fan into the heating chamber, rises through the floor into the drying chamber, and is exhausted from the side flues by a second fan, placed at the other end. Also, by altering the arrangement of the dampers, the same air can be made to circulate from the heating to the drying chamber, and thence by the side flues back to the heating chamber.—W. H. C.

Glue or size, and process of making the same. M. Bonnet. Fr. Pat. 365,285, April 14, 1906. XIV., page 942.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 885.)

Lime, gypsum, water, at 25° C.; The system ——. F. K. Cameron and J. M. Bell. J. Amer. Chem. Soc., 1906, 28, 1220—1222.

Two series of solutions were prepared; in one case solid gypsum was added to solutions containing varying quantities of calcium hydroxide, and in the other lime was added to solutions of gypsum. After two weeks, at 25° C., the solutions were analysed. The results are shown in the following table:—

Calcium sulphate. grms. per litre.	Calcium hydroxide. grms. per litre.	Solid phase.
0·0	1·166	$Ca(OH)_2$
0·991	1·141	"
0·466	1·160	"
0·955	1·215	"
1·214	1·248	"
1·368	1·223	$Ca(OH)_2$; $CaSO_4$, $2H_2O$
1·434	0·939	$CaSO_4$, $2H_2O$
1·442	0·611	"
1·508	0·342	"
1·525	0·175	"
2·003	0·269	"
2·134	0·0	"

It thus appears that the solubility of lime in gypsum solutions is hardly affected by the concentration of the gypsum, but slightly increases with it; whilst the solubility of gypsum in lime solutions decreases regularly as the concentration of the lime increases.—J. T. D.

Gelatinous inorganic salts of the alkaline-earths. C. Neuberg and E. Neimann. Biochem. Zeits., 1906, 1, 166—17 Chem. Centr., 1906, 2, 590—591.

IF dilute sulphuric acid be added to a solution of bariu oxide in methyl alcohol, a coagulum of barium sulpha separates, which retains its gelatinous character aft filtering with the aid of the pump. On drying *in vacu* and even after gentle heating, the product retains th character, forming a very hard, porcelain-like, translucen substance. By boiling the product for a long time with large quantity of water, or more rapidly by addition hydrochloric acid, the ordinary form of barium sulpha is obtained. Colloidal barium phosphate, $BaHPO_4$, ca be obtained in a similar manner On leading carbo dioxide into a saturated solution of barium oxide in meth alcohol, the liquid suddenly sets to a jelly, with evolutio of heat. On draining the jelly with the aid of the pum gelatinous barium carbonate in a pure condition is o tained. If the current of carbon dioxide be kept passi in after the liquid sets, the jelly is converted into a whi powder of the composition, $BaCO_3 + H_2O$, which is solub in a much smaller quantity of water than ordinary bariu bicarbonate is. If the gelatinous barium carbonate or t white powder, $BaCO_3 + H_2O$, be kept under meth alcohol, they gradually dissolve, whereas ordinary bariu carbonate is quite insoluble in methyl alcohol. The sol tions have the appearance of colloidal liquids, conta barium and carbonic acid in the colloidal condition, gi a thick jelly of gelatinous barium sulphate on addition sulphuric acid, and have a high viscosity. The meth alcohol may be partly distilled off from the solutio without injuring the colloidal character of the compoun on evaporating to dryness *in vacuo*, the carbonate remai behind in the form of transparent plates resembling cell loid. The atomic ratio of barium to carbon dioxide the solution is about 1:4. On adding a large quantity water to the solution, a gelatinous precipitate separate Other gelatinous salts of barium and of calcium, strontiu and magnesium were prepared.—A. S.

Sulphur; Action of —— on solutions of metal sal A. Manuelli. Atti R. Accad. dei Lincei Roma, 1906, [1], 703. Chem. Centr., 1906 2, 667—668.

SOLUTIONS of metal salts were mixed in a tube with sulphu the air expelled by carbon dioxide, and the mixture heat to 150°—180° C. In this way a solution of cupric chlori acidified with hydrochloric acid yielded a cuprous sa and potassium bichromate in solution was reduced chromic oxide, a considerable amount of sulphuric ac being formed in both cases. (See also Brückner, this 1906, 476.)—A. S.

Sulphur production in U.S.A. Oil, Paint, and Drug Re Sept. 11, 1906. [T. R.]

THE following abstract is taken from the annual repo of the United States Geological Survey prepared by Edw C. Eckel:—

The sulphur and sulphuric acid supply of the Unit States is at present derived from three sources: (1) nati sulphur, (2) iron pyrites, and (3) a by-product fro sulphides carrying workable percentages of copper, le &c. In 1905 the production of sulphur in the United Sta amounted to 181,677 long tons, valued at $3,706,5 The bulk of this output was from Louisiana.

The following table shows the combined output sulphur and pyrites during the past five years:—

Year.	Quantity. Long tons.	Valu
1901	241,491	$
1902	207,674	
1903	253,187	
1904	334,[illegible]	
1905	454,[illegible]	

Imports.—The following figures show the quantity and value of various grades of sulphur imported into the United States in 1905:—Crude, 83,901 long tons, valued at $1,523,136; flowers of sulphur, 572 tons, valued at $16,037; refined, 779 tons, valued at $19 960; all other (including sulphur lac and other grades not otherwise specified, but not pyrites), 27 tons, valued at $3,353; total value, $1,567,485. During the past three years there has been a steady decline in the imports of sulphur of all grades except refined. The total value of the imports of all grades in 1903 was $3,709,690, or nearly two and one-half times the value of the imports of 1905.

The following table shows the origin of the sulphur imported into the United States in 1905:—

Country.	Quantity. Long tons.	Value. $
England	2,322	51,342
Italy	69,196	1,305,605
Japan	19,887	327,662
Other countries	59	1,588
Totals	91,464	$1,686,197

It will be noted that there is a discrepancy in the total amount of sulphur imported in 1905, as shown in the above table and as previously summarised, which is due to the fact that the summarised figures represent imports entered for consumption.

Pyrites.—In 1905 the production of pyrites amounted to 253,000 long tons, valued at $938,492 as compared with 207,081 long tons, valued at $814,808 in 1904.

The quantity and value of pyrites containing less than 3·5 per cent. of copper imported into the United States during the past five years is as follows:—

Year.	Quantity. Long tons.	Value. $
1901	403,706	1,415,149
1902	440,363	1,650,852
1903	420,410	1,636,450
1904	422,720	1,533,997
1905	511,946	1,774,379

World's production.—The following table shows the pyrites production in the principal producing countries of the world, and also shows to what extent pyrites has supplanted sulphur for acid making:—

Country.	1903. Long tons.	1904. Long tons.
Spain	153,543	159,292
France	324,212	267,268
Portugal	370,253	377,540
United States	233,137	253,000
Germany	168,307	172,030
Norway	127,887	131,499
Hungary	95,560	95,618
Italy	99,857	110,240
Canada	33,039	12,010
Newfoundland	42,000	60,200
United Kingdom	9,639	10,287
Bosnia and Herzegovina	6,484	10,257
Belgium	709	1,058
Sweden	7,670	15,705
Total	1,672,297	1,676,004
Sulphur displaced	752,534	754,202

Consumption in the United States.—The sulphur content of domestic and imported pyrites, which taken together constitute the total domestic consumption, is given in the following table:—

Source.	1904. Long tons.	1905. Long tons.
Domestic sulphur and sulphur content of pyrites	220,478	274,863
Imported sulphur	129,532	84,339
Sulphur content of imported pyrites	190,224	230,376
Total domestic consumption	540,234	589,578

"The sulphur content of imported pyrites in the above table is based on an average of 45 per cent."

Deacon chlorine process. Formation of the catalyser in the ——. J. M. C. Lant and M. Vogtlen. Eng. Chem. Ind., 1906, 29 [A], 513—524.

The authors have made further experiments as to the action of the catalyser in the Deacon chlorine process, more especially to ascertain whether the view that the essential factor is the capacity of the catalyser of absorbing moisture holds good with other substances than cupric chloride (see this J., 1905, 890). Cupric oxide, when heated at 400° C. in a dry mixture of hydrochloric acid and air, yields chlorine and cupric chloride. In 27 hours, 21 per cent. of the cupric chloride produced had decomposed into oxychloride and chlorine; at 400° C. the same amount of chlorine was produced in eight hours. By converting the cupric chloride superficially into oxychloride by too rapid drying, the production of chlorine at 250° C. was prevented, whilst the yield at 400° C. was diminished. The yield of chlorine increases if the proportion of hydrochloric acid in the gaseous mixture be diminished. With copper sulphate at 400° C., and a gaseous mixture containing six parts of air to one of hydrochloric acid, a yield of chlorine amounting to 55 per cent. was obtained in two hours; the copper sulphate remained almost unaltered, only a very small quantity of chloride being formed. The yield was smaller than when cupric chloride was used as catalyser. By the action of dry hydrochloric acid gas, copper sulphate is partially converted into cupric chloride at 400° C. When copper sulphate is used as catalyser, its activity diminishes considerably after some time. Calcium chloride is not very effective as a catalyser. The yield of chlorine (3—8 per cent.) increases slightly with rise of temperature. Barium chloride is inactive even at 526° C. Magnesium chloride, on the other hand, is a good catalyser; it loses a considerable proportion of its chlorine during the reaction. Nickel chloride does not give good results. It is pointed out that the results of these experiments can be explained either by the old hypothesis of Deacon (formation of oxychlorides), or by the authors' theory of the temporary formation of hydrates. The unfavourable results obtained with calcium chloride are probably due to hydrolysis. With magnesium chloride, also, hydrolysis would come into play, but the magnesium hydroxide formed decomposes much more readily than calcium hydroxide. The results of the experiments with copper sulphate are in favour of the hydrate theory, whilst the results previously obtained (*loc. cit.*) as to the stability and activity of oxychlorides at different temperatures are opposed to Deacon's theory. The authors conclude that the Deacon chlorine process is probably a case of double catalysis.—A. S.

Crystallisation process for crystal soda, Glauber's salt, and other solutions. G. Schicht, Vienna. Eng. Pat. 10,917, May 25, 1905.

See Fr. Pat. 354,522 of 1905; this J., 1905, 1161.—T. F. B.

Copper sulphate contaminated with salts of iron; Separation of ——, and the consequent direct extraction of the sulphate of copper from ores. B. Conaders, Massa Marittima, Tuscany. Eng. Pat. 1299, Jan. 17, 1906. Under Int. Conv., Feb. 19, 1905.

See Fr. Pat. 362,442 of 1906; this J., 1906, 697.—T. F. B.

Nitrites; Production of ——. J. T. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen am Rhine, Germany. Eng. Pat. 4210, Feb. 22, 1906.

See Fr. Pat. 363,643 of 1906; this J., 1906, 847.—T. F. B.

United States Patents.

"Sulphurous oxide" [Sulphur dioxide]; Process of recovering —— [from furnace gases]. F. R. Carpenter. U.S. Pat. 829,765, Aug. 28, 1906. X., page 934.

Bisulphite liquor; Process of making ——. N. Heath, Antioch, Cal., Assignor to W. S. Wright and J. W. Stewart, Chicago, Ill., and to J. H. Winslow, Glencoe, Ill. U.S. Pat. 830,996. Sept. 11, 1906.

Continuously generated sulphurous "fumes" are directed into the upper portion of a column of a solution of lime, which continuously descends within a pipe of such height that, in falling, it causes an induced flow of the sulphurous "fumes," with which it intermingles in an attenuated and divided state.—E. S.

Liquefying air and other gases; Apparatus for ——. R. P. Pictet, New York, N.Y., U.S. Pat. 830,613, Sept. 11, 1906.

The apparatus consists of primary and secondary cooling chambers in which liquids of progressively lower boiling points are used; the former surrounds the latter, which, in its turn, surrounds a heat-interchanger having an expansion valve for the gas to be liquefied, which actuates a turbine-motor as it escapes from the valve. The gas or air passes successively through the coils in the series of cooling chambers, and then through the heat-interchanger coil, and the portion which is not liquefied returns over the coils of the interchanger, and assists in cooling the incoming gas. The primary cooling chamber is provided with a second coil, through which the liquid evaporated in the secondary cooling chamber is forced by a pump, in order to be cooled and returned. The liquid evaporated in the primary cooling chamber is compressed by another pump, cooled, and returned for use over again.—W. H. C.

French Patents.

Nitric acid or anhydride; Process for producing —— from atmospheric air. Salpetersäure Ind.-Ges., m.b.H. Fr. Pat. 365,070, April 10, 1906.

This invention relates to processes in which nitric acid or anhydride is produced from atmospheric air, or air mixed with oxygen, at a temperature exceeding 1200° C., and in which sudden cooling is effected by causing the gases of reaction to traverse cooled surfaces, or by injecting into them inert cold liquids or gases. The present process consists essentially in employing, as cooling agent, the cooled reacting mixture which results from the process itself. The rapidity of the cooling may be regulated by increasing or reducing the quantity of the reacting gases, already cooled, added to the gases to be cooled.—E. S.

Liquid sulphur dioxide; Tube for measuring ——. P. V. Pacottet. Fr. Pat. 365,224, April 13, 1906.

This arrangement for measuring definite volumes of liquid sulphur dioxide consists of a graduated glass tube connected to the reservoir of the liquid by a three-way cock. The top of the glass tube ends in a small hole, which can be closed or slightly opened by a pointed screw. This screw is so regulated that on opening the cock, the liquid fills the tube to any requisite volume without boiling or evaporating. On again turning the cock, the measured volume of liquid escapes into the vessel to be charged.—F. Sheen.

Salt; Manufacture of white —— from rock salt. H. Tee, Fr. Pat. 364,731, March 29, 1906. Under Int. Conv., March 29, 1905.

See Eng. Pat. 6611 of 1905; this J., 1906, 697.—T. F. B.

Magnesium and zinc peroxides; Manufacture of rich ——. F. Hinz. Fr. Pat. 364,825, April 2, 1906.

A soluble magnesium salt, such as the chloride, is dissolved in a concentrated neutral or slightly acid solution of hydrogen peroxide, and sodium peroxide is added to precipitate magnesium peroxide, which is separated from the solution, and, without being washed, is dried at about 70° C. The dried mass is powdered, washed, and again dried. Zinc peroxide is similarly formed.—E. S.

Ammoniacal cupric hydroxide (Schweitzer's reagent); Recipient for the preparation of ——. E. Mertz. Fr. Pat. 364,911, April 4, 1906.

The recipient is conical in form, narrowing towards the top, so that the copper scraps subjected within to the action of ammonia may descend as the lower portions dissolve. The recipient is jacketed for circulation of a cooling agent. The narrow cover of the recipient is closed by a screwed-down cap. Means for discharging and for cleaning the vessel are shown.—E. S.

Alkali bicarbonates; Manufacture of —— [for production of carbon dioxide]. J. G. Behrens. Fr. Pat. 365,059, April 10, 1906.

Iron pipes, charged to about half their capacity with anhydrous sodium carbonate, are heated to the temperature at which, under atmospheric pressure, sodium bicarbonate evolves carbon dioxide. At this temperature, generator gas, containing carbon dioxide with water vapour in molecular proportions, together with nitrogen, is admitted under pressure. The following reaction is stated to occur: $Na_2CO_3 + H_2O + CO_2 = 2NaHCO_3$. The residual nitrogen is discharged and the pressure released, the temperature remaining unaltered, when the bicarbonate formed decomposes, and the pure carbon dioxide evolved is withdrawn for liquefaction. The sodium carbonate remaining is then ready for exposure under pressure to the renewed action of the generator gas.—E. S.

Ammonium nitrate; Manufacture of —— [from distillation gases]. W. Feld. Fr. Pat. 365,409, April 19, 1906.

A solution of a nitrate of an alkaline-earth is brought into contact with distillation gases from coal or the like (freed from hydrogen sulphide) containing ammonia and more or less carbon dioxide. The alkaline-earth is thus precipitated as a carbonate, and ammonium nitrate remains in solution. In case a concentrated solution of an alkali nitrate, such as sodium nitrate, is used as described, and should the carbon dioxide present in the gases passed through be insufficient, when sufficient ammonia has been absorbed, to form sodium bicarbonate, the solution is submitted to the further action of carbon dioxide from any other convenient source, to complete the formation of the bicarbonate, the bulk of which separates, leaving ammonium nitrate in solution, as in the former case. The solution may be evaporated to obtain the solid salt.—E. S.

Ferrocyanides; Process for obtaining —— from gases of distillation. W. Feld. Fr. Pat. 365,410, April 19, 1906.

To abstract cyanogen from coal gas and other gases containing it, a washing solution is used to which, for example, a mixture is added containing two molecules of ferrous chloride to one molecule of calcium ferrocyanide, which latter may be in some excess of this proportion. A precipitate is thus produced, and slaked lime is added. As the cyanogen-carrying gases pass through the suspended mixture, calcium ferrocyanide is formed. Various modifications of the process are given. The mud remaining from the reaction, after separation of excess of liquid, may be again used similarly, with addition of milk of lime.—E. S.

Oxygen generator. G. F. Jaubert. Fr. Pat. 361,537, June 5, 1905.

The generator consists of a closed vessel formed of drawn steel, and charged nearly to its full capacity with briquettes, containing as a base such oxygenated salts as chlorates, perchlorates, or nitrates. (See Fr. Pat. 350,377 of 1904 and Addition thereto; this J., 1906, 160 and 835.) It is nearly immersed in a vessel through which a current of cold water flows. Two such generators are shown, immersed in a common vessel, each communicating by a valved tube with a pipe leading to a column charged with caustic soda or the like, to absorb acid fumes or carbon dioxide, whence the oxygen liberated by firing the briquettes in the generators passes into an iron receiver.

When a pair of generators is used, they may be worked in rotation, being discharged alternately, so that there may be no interruption in the production of the oxygen. —E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 885.)

Chert mining in England and Wales. H. L. Terry. IX., next column.

Glass industry of the United States. *U.S. Geol. Survey,* Oil, Paint, and Drug Rep., Sept. 17, 1906. [T.R.]

THE value of glass products manufactured in the United States in 1905 is in round numbers $65,000,000. The cost of material used approximates $18,000,000, and in this the cost of glass sand was somewhat more than $1,000,000, exclusive of freight charges. Within the half-century preceding 1900 the value of glass products showed an average increase of 70 per cent. for each decade, and the growth is still vigorous. Glass of four general classes—plate, window, green bottle, and flint—is made in the middle Mississippi basin from materials obtained, for the most part, in the region. The majority of the glass factories are grouped into two districts—the St. Louis district and the South-Eastern Kansas district. Where coal is the basis of the fuel, if it requires 1 ton of coal to 1 ton of glass, nearly as much coal by weight as raw material has to be transported, but the freight rates on sand, lime, and salt cake are decidedly higher than on coal for a given distance. Therefore, it is important that plants using coal should also be relatively near a supply of sand. When natural gas in a fresh field is the fuel, it is so much cheaper than producer gas made from coal near the mines that the glass can stand the cost of a long haul for sand and other materials if necessary. Eight factories are situated in the St. Louis district—two at St. Louis and one at Valley Park, one at Crystal City, Mo., and one each at East St. Louis, Belleville, Alton, and Litchfield, Ill. Producer gas from southern Illinois coal is commonly employed as fuel, although the furnace at Alton is fired direct with coal. Plate glass is made at Crystal City and at Valley Park. The factory at Crystal City has been established about 30 years. Its present capacity is two furnaces of 20 pots each. The factory at Valley Park, erected within the last few years, contains four furnaces of 20 pots each.

The manufacture of glass in the Kansas gas belt was begun less than three years ago. There are now 21 plants all using natural gas for fuel. Many of them have been moved from the waning gas fields of Indiana, attracted by the cheapness and abundance of gas in the new field. Sand is supplied mostly from the belt west of St. Louis. A little sand has been imported from the Ottawa, Ill., district. In regard to limestone supplies, the Kansas factories are situated more advantageously. Some crushed limestone has been obtained from neighbouring cement mills, and a portion is shipped from Sedan. Still it seems to be necessary to import the greater portion of it from Missouri points. Salt cake is brought from Argentine, Kan. Illinois and Missouri together furnish at present about 350,000 short tons annually, nearly 40 per cent. of the total supply of glass sand in the United States. Pennsylvania produces about 33 per cent., and therefore ranks first in quantity of this product, with Illinois second, and Missouri third. According to the latest complete statistics (or 1905) the average value of glass sand per ton in Pennsylvania was $1.31; in Illinois, 63 cents; and in Missouri, 60 cents. This difference in price is accounted for in part by the fact that Pennsylvania sand is somewhat more expensive to produce, being made from harder rock.

ENGLISH PATENT.

Glass-melting furnaces. W. P. Gibbons, Lower Gornal, Staffs., and R. Masters, Dudley, Worcester. Eng. Pat. 15,560, July 29, 1905.

IN the glass-melting furnace described, each pot is heated independently of the others, producer gas being used as fuel. The invention is described both as applied to an old furnace burning solid fuel in a central fireplace, which is suitably altered, and also as to an entirely new furnace. Essentially, each pot is placed in one of a series of small glass-melting furnaces, arranged in one or more rows. An arched gas producer or main gas flue extends underneath these small furnaces, the arches of the gas flues having secondary air passages receiving secondary air from passages underneath the gas flues. Communicating with these gas flues and with the furnaces, are placed combustion chambers, the arches of which are supplied with another set of air passages. Uptakes provided with dampers lead from the furnaces to the outlet flues, by means of which the heat of each furnace can be regulated independently of the others.—A. G. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 886.)

Chert mining in England and Wales. H. L. Terry. Paper read before the Institution of Mining and Metallurgy, May 17, 1906.

CHERT, an impure form of flint, is a silicious rock containing calcium carbonate as a normal constituent. It differs from chert in physical properties; for instance, a sharp blow will break a flint into two pieces, but will splinter a piece of chert into numerous fragments. Chert beds occur at many geological horizons, but those of the carboniferous formation are the most important economically, and are mined in the millstone grit of North Wales, in the carboniferous limestone and in part of the Yoredale shale of Derbyshire, and in the Upper Yoredales from the underset limestone to near the base of the millstone grit in Yorkshire, the districts being Halkyn Mountain and Gronant, Bakewell, and Swaledale respectively. The chief use of chert is for the pavers, and runners of wet grinding mills for grinding calcined flints, china-stone, and bones in the manufacture of pottery. The pavers form the bed of the pan, and are usually from 10 to 18 in. thick, and otherwise of variable dimensions; they are chiefly supplied from Flintshire, as the beds there are of about the required thickness, and consequently less dressing of the blocks is required. The large blocks, or runners, travel over the pavers at a rate of about 15 revolutions per minute, and vary very much in size and weight, 16 cwt. being a common weight. The annual consumption of chert may be taken roughly at 8,000 tons, the price varying from 25s. to 42s. per ton delivered, according to quality.

The chert from Swaledale has a flinty appearance, is semi-transparent, of a bluish tinge, and has a characteristic uniform fracture. It is about 7 in the scale of hardness, and has a sp. gr. of 2·59. It exhibits no regular cleavage planes, but tends to split along irregular pressure planes. It consists of nearly pure silica, with a small amount of ferrous silicate and carbonate of lime. The latter is evidently due to infiltration, and great care is necessary in selecting an average sample for analysis. The following analyses, made by the author, may be taken as representative:—

Analyses of chert sold to the Potteries.

	Derbyshire.		Swaledale.	Flintshire.
	(1.)	(2.)		
Water	0·54	0·60	1·61	1·62
Silica	82·53	63·40	95·60	93·56
Ferrous oxide	—	—	1·02	4·52
Ferric oxide	1·05	2·34	—	—
Carbonate of lime	15·88	33·66	1·80	0·43
	100·00	100·00	100·13	99·83

IN Derbyshire the percentage of limestone is the most important factor in determining the value of chert property,

and in the carboniferous limestone areas of the North of England, though there is a large amount of good chert, yet the bulk of it is valueless, owing to the tendency to split up into fragments during the dressing operation. It may be mentioned that a 2-ton Swaledale chert runner working on flint alone lasted 10 months, by which time it was reduced to 7 cwt. The paper also contains a full description of the mining details involved.—W. C. H.

Cement; Influence of the sulphur dioxide contained in illuminating gas on the determination of the loss on ignition of ——. L. von Szathmáry. XXIII., page 954.

Cement production in U.S.A. in 1905. Bd. of Trade J., Sept. 13, 1906. [T.R.]

A RECENTLY published bulletin of the United States Geological Survey gives the following particulars of the production of cement in the United States in 1905:—

	Quantity.	Value.
	Barrels.	Dols.
Portland cement	35,246,812	33,245,867
Natural ,, ...	4,473,049	2,413,052
Puzzuolana ,, ...	382,447	272,614
Total production in 1905	40,102,308	35,931,533
Corresponding total for 1904	31,675,257	26,031,920

The total capacity of United States cement plants for 1905 is estimated at 129,000 barrels per day; it is expected that before the close of 1906 the total possible production will exceed 140,000 barrels per day. Some concentration of interests in the cement industry is noted, but the possibility of a trust or combination to bring about unduly high prices is dismissed by the bulletin as out of the question.

Magnesium carbonate manufactures. Italian Customs decision. Bd. of Trade J., Sept. 13, 1906. [T.R.]

MANUFACTURES of carbonate of magnesia mixed with asbestos are assimilated to manufactures of magnesia cement, which, in accordance with the official index to the Tariff, are dutiable as "earthenware" under No. 267 of the Tariff.

ENGLISH PATENTS.

Artificial stone; Manufacture of ——. B. Alexander-Katz, Görlitz, Germany. Eng. Pat. 3182, Feb. 9, 1906. Under Int. Conv., Sept. 22, 1905.

SEE Fr. Pat. 362,418 of 1906; this J., 1906, 698.—T. F. B.

Kilns; Brick and like ——. J. T. Price, Brierley Hill, Staffs. Eng. Pat. 7464, March 28, 1906.

THE object of the invention is to economise heat by causing the burnt gases from the burning chamber to effect the drying of green goods in another chamber. For this purpose, the kiln is provided with two or more separate interchangeable burning and drying chambers, and with one central or side stack. Flues are so arranged in the walls of each chamber that the hot gases from one chamber, on their way to the chimney, have to pass around and then through the second chamber.—A. G. L.

Cement; Manufacture of ——. W. Jeroch, and Deutsche Ferrit-Cement Ges. m. b. H., Berlin. Eng. Pat. 3655, Feb. 14, 1906. Under Int. Conv., Sept. 28, 1905.

SEE Fr. Pat. 363,103 of 1906; this J., 1906, 848.—T. F. B.

Fireproof or heat-resisting surfacing composition or cement. R. J. Crowley and F. F. Payne, London. Eng. Pat. 8627, April 10, 1906.

FOUR parts of granular corundum are finely ground, mixed with one part of powdered graphite, and made into a paste with a 10 per cent. solution of sodium silicate. The composition is intended for use both as a heat-insulating and fireproof material in building construction, &c., and also as a non-absorbent lining for furnaces and crucibles.—A. G. L.

UNITED STATES PATENTS.

Brick; Method of making refractory [magnesia] ——. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 829,427, Aug. 28, 1906.

REFRACTORY magnesia brick is prepared by heating magnesia to a temperature sufficient to vitrify it, cooling, grinding the vitrified material to powder, pressing it into shape, and subjecting it to a temperature high enough to cause some of the magnesia to sublime without fusing. —A. S.

Cement; Process of burning ——. B. E. Eldred, New York. U.S. Pat. 829,956, Sept. 4, 1906.

THE powdered material is continuously burnt by passing it through two independent reverberatory furnaces, in the first of which it is calcined, the operation being carried to incipient fusion so as to reduce the quantity of dust produced on entering the second furnace, in which the material is clinkered in a flame "regenerated by products of combustion" abstracted from this furnace.—A. G. L.

Cement clinker; Apparatus for making ——. B. E. Eldred, Bronxville, N.Y. U.S. Pat. 829,957, Sept. 4, 1906. (See preceding abstract.)

AN inclined horizontal kiln is provided with a number (generally two) of successive rotating chambers, forming sections having stationary partition walls between adjacent sections. These walls allow of the transit of solid material from one chamber to the other, but form thermal insulators between the chambers. The chambers are fed with gas from a producer, and are supplied with separate means of firing. The calcining of the materials takes place in one chamber, and the clinkering in another.—A. G. L.

Cement blocks; Process of rendering —— waterproof. J. M. Rauhoff, Tinley Park, Ill. U.S. Pat. 830,003, Sept. 4, 1906.

METALLIC iron in the form of fine dust held in suspension in water or other liquid is supplied to the surface of the cement blocks or other substance. The iron is then allowed to oxidise and expand, and thus fill the pores in the surface of the block.—A. G. L.

FRENCH PATENT.

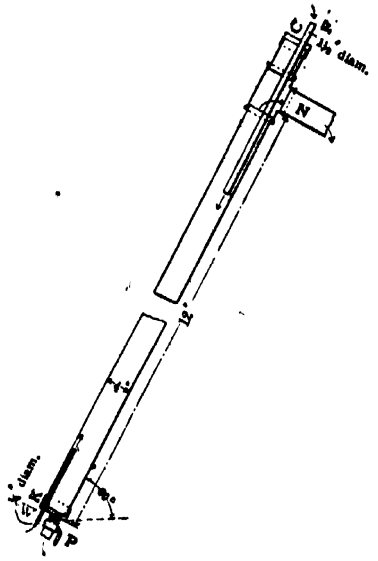
Agglomerations of sawdust and magnesia; Addition of extra hard materials to ——. H. Coppin. Fr. Pat. 364,890, April 4, 1906.

THIS patent covers the addition of very hard materials, such as silica, porphyry, emery, carborundum, corundum, &c., to agglomerated products of sawdust and magnesia, and of chlorides, such as prismalith, stucolyth, xylolith, &c., for the purpose of increasing the resistance of these products to wear and tear in their various applications. —W. C. H.

X.—METALLURGY.

(*Continued from page* 899)

Sulphur in iron. R. Baumann. Metallurgie, 1906, 3, 416—417; Science Abstracts, 1906, 9A, 441.



THE author describes a simple method for detecting the distribution of sulphide particles in sections of iron or steel. A piece of photographic silver bromide paper is soaked in dilute sulphuric acid, allowed to drain, and then pressed against the surface of the section of iron, which has previously been ground flat, and cleaned from grease. At parts where sulphide particles are present, sulphuretted hydrogen is evolved, and produces a blackening of the paper, which can afterwards be fixed and washed in the usual manner.—A. S.

Sodium cyanide; A negative experience with —— [*in gold extraction*]. W. Magenau. Eng. and Mining J., 1906, 82, 363.

ON using sodium cyanide in place of potassium cyanide

for the extraction of gold from a complex ore containing sulphides of copper, iron, and arsenic, poor yields were invariably obtained, in some cases as low as 20 per cent., as compared with 75 per cent. when potassium cyanide was used. The sodium cyanide used was almost pure; it contained a small quantity of sulphide, but not nearly so much as the potassium cyanide with which good results were obtained.—A. S.

Sands; Simple device for separating —— from slimes. [*Ore treatment*]. C. De Kalb. Eng. and Mining J., 1906, **82**, 206.

The simple device shown in the accompanying figure has proved very efficient as a separator for removing fine sand from slime. It consists of a 4-in. pipe, 12 ft. long, set at an angle of 60°. At the upper end the pipe is provided with a 4-in. T and nipple, N, above which is a short length of 4-in. pipe fitted with a cap, C, through which passes a 1¼-in. pipe, F, extending 2 ft. below the nipple. The lower end of the pipe is also fitted with a cap, K, through which pass a 2-in. discharge pipe, P, and a 1¼-in. pipe, W, which extends 2 ft. above the cap. The ore-pulp is introduced through the pipe, F, and water is delivered through W. The slime is carried upwards by the ascending current of water, and overflows through the nipple, N, whilst the washed sand is drawn off through P.—A. S.

Copper matte (coarse metal); Loss of silver and copper in refining —— to highly concentrated matte and to black copper respectively. E. Günther. Z. angew. Chemie, 1906, **36**, 1558—1559.

According to Ger. Pat. 160,046 (this J., 1905, 897), coarse metal is refined by the converter process so as to yield a highly concentrated matte containing 72—80 per cent. of copper, and this product is used directly as anode material for the production of pure electrolytic copper, with simultaneous recovery of the gold and silver. In this manner the various steps involved in the usual process of first refining the coarse metal to black (crude) copper are avoided. The author has made comparative experiments to determine the losses of silver and copper in the two processes. The results show that on Bessemerising the coarse metal to highly concentrated matte, no appreciable volatilisation of metals occurs, whereas on refining up to black copper the loss may be very considerable.—H. B.

Copper residues. Italian Customs decision. Bd. of Trade J., Sept. 13, 1906. [T.R.] [illegible]

Residues of copper salts, insoluble, not utilisable directly, but fit only to be treated in order to extract the copper therefrom, are to be free of duty as copper ores under No. 208 (c) of the Tariff.

Brass; Effect of arsenic on——. E. S. Sperry. Mech. Eng., 1906, **17**, 763—764. Science Abstracts, 1906, **9A**, 437.

The effect of arsenic up to 0·5 per cent. on the properties of Muntz metal (copper, 60; zinc, 40 per cent.) was examined. Sharper and cleaner castings were obtained from the alloys containing arsenic than from those free from that substance. The ductility of the alloys was improved by addition of arsenic up to 0·02 per cent., probably owing to the reducing action of the latter on cuprous oxide. With higher percentages of arsenic the alloys became brittle, and cracked in the rolls.—A. S.

Vanadium; New occurrence of —— in Peru. Foster Hewett. Eng. and Mining J., 1906, **82**, 385.

A rich vanadiferous mineral, for which the name *patronite* is proposed, has been discovered by A. R. Patron in the neighbourhood of Cerro de Pasco, Peru. It has a dark green colour similar to that of olivenite, and shows a conchoidal to uneven cleavage, and a greenish-black streak; its sp. gr. is 2·65, and hardness, 3·5. An analysis by J. O. Handy gave the following results:—Moisture, trace; silica, 10·88; alumina, 3·85; iron, 2·45; vanadium, 18·08; sulphur, 54·06; molybdic oxide, 0·50; sulphur soluble in carbon bisulphide, 6·55 per cent. W. F. Hillebrand, of the U.S. Geological Survey, reports that the vanadium can be completely extracted by caustic alkali; the iron in the residue is probably in the form of pyrites. After dissolving the pyrites, a black residue containing carbonaceous matter is left. The vanadium appears to be present as a sulphide. The mineral occurs as a vein about 8 ft. thick, in which the vanadium content varies from 9·5 to 15·7 per cent. Associated with the vein is a vein of asphaltite. The latter yields 3·31 per cent. of ash, of which 0·533 per cent. is vanadic oxide. A material apparently intermediate in composition and nature between the vanadiferous mineral and the asphaltite occurs between them. It is black, has a conchoidal fracture, and contains 2 per cent. of ash, which is highly vanadiferous. This material has a vesicular structure, some of the cavities being filled with coked asphaltite. Along a portion of the outcrop the vanadiferous mineral has been oxidised to a brownish substance, resembling limonite, containing as much as 45 per cent. of vanadium oxide. W. F. Hillebrand reports that this oxidation product contains about 45 per cent. of vanadium in the quinquevalent state, about 15 per cent. of water, a small proportion of sulphuric acid, 14—15 per cent. of iron oxide, 20 per cent. or more of silicious gangue, and 0·9 per cent. of molybdic oxide.—A. S.

Aluminium-lead and aluminium-bismuth alloys; Determination of melting-points of —— by thermoelectric pyrometers. H. Pécheux. Compt. rend., 1906, **142**, 397—398.

The author has determined the melting points of these alloys by means of two couples, one platinum-iridio-platinum, the other nickel-copper. The temperatures determined were:—

Per cent. of aluminium.	Platinum-iridioplatinum.	Nickel-copper.
	°C.	°C
Lead alloys—		
92	643	645
94	648	652
96	637	635
Bismuth alloys—		
75	720	719
85	650	674
88	663	664
94	655	650
Aluminium, pure—	635	630

Up to 720° C., then, a nickel-copper junction, well protected from oxidation, can be used instead of the much more expensive platinum combination for the measurement of temperatures.—J. T. D.

"*Silicones.*" O. Boudouard. Bull. Soc. Chim., 1906, 35, 710—715.

Silicones may be prepared from steels rich in silicon by heating with hydrochloric acid until all the iron is dissolved, washing the residue thoroughly and rapidly with cold water, and drying for some days *in vacuo* over sulphuric acid. Amorphous powders varying in colour from white to a deep grey are thus obtained. These contain small quantities of carbon and moisture, but exhibit the general properties of silicones, being insoluble in acids, excepting hydrofluoric acid, liberating hydrogen with alkalis, and reducing metallic salts in the presence of alkalis. They are apparently decomposed by prolonged heating with hydrochloric acid. The author regards them as mixtures of silicoformic anhydride, $Si_2H_2O_3$, and silico-oxalic acid, $Si_2H_2O_4$.—F. Sodn.

Foam-structure of matter; Transition from the liquid to the solid state, and the ——. G. Quincke. Roy. Soc. Proc., 1906, 78A, 60—67.

The author has previously (this J., 1905, 1259) described the foam-structure of ice, and he now states that phenomena similar to those observed in the freezing of water occur in all bodies in nature. The present communication deals mainly with the foam-structure of solid bodies, especially of metals. Molten metals on cooling form first a liquid jelly, and later a solid jelly. The walls and contents of the foam-cells of such a jelly still consist of viscous liquid, *i.e.*, the jelly itself is still liquid—like ice—at temperatures lower than the melting points of the respective metals. The welding of two pieces of metal corresponds to the running together of the cell walls and cell contents of two lumps of jelly, or the regelation of ice. The surfaces of solidified drops of pure molten metals (gold, silver, platinum, palladium, iridium, indium, copper, zinc, iron, nickel, cobalt, bismuth, sodium, potassium, mercury) show a network of straight lines or arcs of circles (usually inclined to one another at 120° or 90°), or foam-walls with embedded lens-shaped masses (compare Ewing and Rosenhain, this J., 1901, 1115; Holborn and Henning, this J., 1902, 1332). Similar phenomena are to be observed on the surface of solidified drops of sulphur and selenium, and on the surface of carbon which has been distilled by means of the electric arc in a magnetic field, and deposited on the cathode. The shapes of the bounding surfaces of the metallic grains formed on cooling molten metals, and the arcs of circles in the network of lines on the surface of metals raised to red or white heat, indicate that these bounding surfaces are not crystalline faces, as has hitherto been believed, but solidified oily foam-walls, which, as in the glacier-grains of ice, enclose foam-cells with contents differing from the walls. On heating the metals nearly to their melting points, larger foam-cells with fewer foam-walls are formed, just as the glacier-grains of ice run together and become larger, owing to the bursting of the foam-walls. A network of lines or foam-walls similar to that on the natural surface of solidified metals becomes visible also on artificial surfaces of metal castings when these are polished, or suitably etched by acids or other liquids (see Beilby, this J., 1901, 992; 1903, 1107, 1108, 1166), the foam-walls being attacked or dissolved either more easily or less easily than the contents of the foam-cells. From a study of Heyn's photographs of etched surfaces of slowly cooled iron containing varying amounts of carbon, it is concluded that iron with 0·05 per cent. of carbon shows fine circular foam-walls of cementite enclosing foam-cells, 0·04—0·1 mm. in diameter, filled with ferrite, the foam-walls meeting at angles of 120°, 90°, &c. Islets of perlite are suspended in the partly invisible foam-walls. When the iron contains more carbon, the cementite separates periodically in parallel layers, or as parallel cylindrical tubes with bulgings and rounded heads, or as spherical foam-walls enclosing "foam-lenses" and foam-cells, 0·001—0·003 mm. in diameter. The tubes, lenses, and foam-cells are filled with ferrite, and also surrounded by ferrite. The greater the percentage of carbon, and the more quickly the molten iron is cooled, the less is the distance of the layers from one another, and the smaller are the foam-cells, just as in the case of ice containing a dissolved salt. The shapes of the microscopic structures in solidified iron containing carbon are the same as in ice containing a salt. The cementite corresponds to the "oily" salt solution in freezing water. Other foreign substances in iron—carbon in the form of graphite and temper carbon, silicon, phosphorus, sulphur, air or other gases, and other metals such as manganese and nickel—even if present only in small quantities, are able to considerably modify the surface tension, melting point, and viscosity of the foam-walls and of the contents of the foam-cells and the size and shape of the foam-cells or glacier-grains of the iron.—A. S.

Bismuth production in U.S.A. Oil, Paint, and Dru Rep., Sept. 13, 1906. [T.R.]

The following is taken from the Annual Report of th U.S. Geological Survey, prepared by C. C. Schnatterbeck:—

During 1905 the marketed production of bismuth or in the United States amounted to 24,405 lb., containin approximately 2288 lb. of metal, valued at $4187. Th sales in 1904 were 5184 lb. of ore, valued at $314. In 190 and 1903 there were no transactions.

Metallic bismuth to the amount of 148,589 lb., valued a $318,007, was imported into the United States in 190 as against 185,905 lb., valued at $339,058 in 1904 147,295 lb., valued at $235,199 in 1903; and 190,837 lb valued at $213,704 in 1902. Comparatively little bis muth salt is imported, suggesting expansion in the domesti manufacturing industry.

Features in the bismuth industry in 1905 have been th shipment of ore from a new deposit in California, th resumption of mining on the Ballard property in Colorad and the reduction in the combination's price of the meta in London from 10s. ($2.43) to 5s. ($1.22) per lb. Mor attention has also been given to the development of th deposits in Saxony, the most important in the world as well as to those in Austria, Bolivia, and Australia In the United States the consumption of metallic bismut in 1905 was between 175,000 and 200,000 lb. Most o this was imported free of duty. Small quantities o bismuth salts for chemical and pharmaceutical purpose have also been imported. It is a fact worthy of note tha the import trade has grown over 50 per cent. in the las 10 years, while the bismuth-mining industry in the U.S.A has shown comparatively little progress. This is no because there is a scarcity of bismuth-bearing deposits i the United States, as they have been found in Colorad California, Nevada, Arizona, and Utah, but it is rather th result of inadequate methods of smelting the metal her The refined bismuth imported from Great Britain an Germany frequently contains over 96 per cent. of pur metal, whilst crude metal will contain 93 to 96 per cent. having as impurities antimony and arsenic, or othe metals.

Mining for bismuth in the United States is at presen centred at Leadville, Colo., where the newly incorporate Ballard Consolidated Mining and Milling Compan resumed shipments on June 1, 1905, from properties tha have heretofore been owned and leased by individuals The new deposit in California, from which early in th year were shipped 20 or 30 tons of ore, is situated 55 mile east of Banning. Of late there has been a good enquir in the market for bismuth sulphide ore, and it would no be surprising if in the near future the metal were recovere from the immense placer dumps of schirmerite (containin sulphides of bismuth, silver, and lead) in Montana an other Western States.

Manganese and manganiferous ores; Production of —— in U.S.A., in 1905. Bd. of Trade J., Sept. 13, 1906. [T.R.

The production of manganese ore in the United State in 1905 amounted to 4,118 tons, valued at $36,214, a compared with 3,146 tons, valued at $29,466, in 1904 The production of manganiferous iron ore amounted t 769,256 tons, valued at $1,554,969; that of argentiferou

manganiferous iron ores amounted to 61,736 tons, valued at $276,299; and that of manganiferous zinc ores to 90,289 tons, valued at $90,289. This makes a total production of manganese and manganiferous ores in the United States in 1905 of 945,401 tons, valued at $1,951,771.

Tantalum minerals in U.S.A. Mineral Resources of U.S.A. for 1905. [T.R.]

A TANTALUM mineral has recently been discovered at a felspar quarry at Henryton, Carroll county, Md., about 28 miles from Baltimore. It occurs in irregular masses and rough crystals. A specimen sent to the Westinghouse Electric Company at Pittsburg on analysis gave the following result:—Tantalic oxide, 38·19; niobic oxide, 13·21; manganese oxide, 10·48; ferric oxide, 21·42; and silica, 12·98 per cent.

Some material obtained from Tinton, S.D., was concentrated at Portland, Oregon, and a heavy black mineral was obtained with *cassiterite* and *scheelite* as concentrates from the Wifley table, which, upon analysis, gave 44 per cent. of tantalic oxide and 30·5 per cent. of niobic oxide, these determinations having been made by W. F. Hillebrand, of the United States Geological Survey. The specific gravity of the mineral was determined to be 6·8.

Mineral production of Spain. Eng. and Mining J., Sept. 8, 1906. [T.R.]

THE output of mineral and metal products in Spain for the past two years is officially reported, in metric tons, as in the subjoined tables. The production of fuels was as follows:—

	1904.	1905.
Anthracite	119,096	135,099
Bituminous	2,903,671	3,067,826
Lignite	100,773	168,994
Total	3,123,540	3,371,919

Of the more important metallic ores, the output was:—

	1904.	1905.
Copper ore	2,646,126	2,621,054
Iron ore	7,964,748	9,077,245
Manganese ore	18,732	26,020
Lead ore	93,230	105,113
Mercury ore	27,185	26,485
Silver-lead ore	177,104	160,381
Silver hematite ore	122,109	152,027
Zinc ore	156,329	160,567

Other less important metallic ores were produced in the following quantities:—

	1904.	1905.
Antimony ore	245	77
Arsenic ore	3,510	4,790
Bismuth ore	5	14
Cobalt ore	25	25
Pyrites	161,841	179,079
Silver ore	303	540
Tin ore	299	209
Tungsten ore	60	375

A large part of the pyrites mined in Spain—most of it exported—is included in copper ore, as it carries some copper. The pyrites in the table above is only that which carries no copper.

In the final table are given the output of the lesser non-metallic minerals:—

	1904.	1905.
Amblygonite	90	120
Asphaltum	3,761	5,725
Bituminous rock	100	750
Barytes	453	290
Graphite	20	15
Kaolin	1,700	720
Magnesite	1,129	1,446
Phosphate rock	3,595	1,370
Salt	542,088	493,451
Sulphur	40,230	36,153

The total value of this production in 1905 was estimated at $37,320,435. Statistics of metallurgical production in 1905 are not yet available. The principal metals smelted in Spain are zinc, copper, iron, lead, and mercury. The total metallurgical output in 1904 was valued at $44,166,631, which was probably largely exceeded by that of last year.

Mineral resources of Ceylon. Bd. of Trade J., Sept. 13, 1906. [T.R.]

THE Report for 1905 on the trade of Ceylon, just issued by the Colonial Office, after referring to the discovery of thorianite, states that monazite has also been discovered, and has proved to be of widespread occurrence in Ceylon river sands. Small deposits of cassiterite and galena have been found, as well as molybdenite. The output of plumbago, in spite of the falling of value from Rs. 20·88 per cwt. in 1902 and Rs. 12·50 in 1903 and 1904 to Rs. 11·70, which in some cases leaves barely sufficient margin to cover expenses, shows an increase over previous years, and 612,848 cwt. were exported.

Mineral resources of Algeria. For. Off. Ann. Series, No. 3712. [T.R.]

THE report of the British Vice-Consul at Bône contains an account of the mineral resources of that locality. The districts of Souk-Ahras and Tébessa, he says, abound in zinciferous deposits still unworked. Discoveries of carbonate of lead at Batna and of cinnabar near Jemmapes are not being worked owing to lack of capital. Peroxide of manganese, said to contain 65 per cent. of metal, is found one mile from Ain-Yagout. Antimony mines near Guelma are for sale. The province of Constantine, says the Vice-Consul, contains more ferruginous beds than the provinces of Algiers and Oran put together

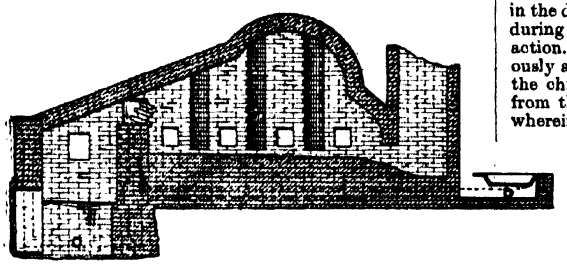
Cast-iron. E. and S. Wallis, Derby. Eng. Pat. 9453, April 23, 1906.

THE improved cast-iron is made by melting in a cupola furnace, in the order given, and mixed with a suitable quantity of fuel: 3 cwt. of Warner pig-iron No. 4, 2 cwt. of Warner pig-iron No 3, 1 cwt. of Stanton pig-iron No. 3, 4 cwt. of good scrap iron, consisting preferably of old machine castings, and 5 lb. of mild steel in small pieces. The mixture of pig-irons used contains approximately: Carbon, 3·33; silicon, 1·65; sulphur, 0·04; phosphorus, 0·30; and manganese, 0·47 per cent. Other irons of similar composition may be used instead of those given above, and the steel may be melted separately, and then intimately mixed with the molten iron if desired.—A. G. L.

Zinc and lead-sulphide ores; Treatment of ——. A. H. Imbert, Grand Montrouge, France. Eng. Pat. 10,303, May 2, 1906.

THE ore is mixed with lime and ferric oxide or other suitable substances, and heated in a retort connected with a suitable condenser to about 1100° C., whereby, it is stated, a perfectly fluid homogeneous bath is produced. If new metallic iron or other metal in a solid or liquid state be introduced, it is found that the zinc is almost completely volatilised in about a quarter of an hour, leaving a perfectly liquid mass, which on being run out and cooled, consists of an upper layer of slag and a lower stratum of sulphide containing scarcely any zinc. When lead is present in the ore, most of it is found in a metallic state beneath the sulphide, but a small proportion passes over with the zinc fumes.—J. H. C.



United States Patents.

Furnace for the immediate production of metal from ores; and metallurgical process. O. B. Dawson, Caldwell, N.J. U.S. Pats. 829,574 and 829,575, Aug. 28, 1906.

The invention relates to a process of producing directly from ores, metals which do not form carbides at the temperature of a gas-fired furnace. The ground ore is subjected, in the absence of air and without any flux, at a temperature below the melting or volatilising point of the metal, to the action of finely-divided carbon and of the carbon monoxide which is instantaneously produced therefrom. The process is carried out in a rotating reducing furnace, heated internally by a flame, which is introduced at one end, in such a manner that it can be directed to any part of the charge or hearth. Means are provided for regulating the character of the flame. The ends of the furnace are covered with caps lined with fire-proof material, and an inspection tube is provided passing through the stack and the cap at the flue end of the furnace.—A. S.

Furnace; Metallurgical ——. G. W. Shear, Joliet, Ill. U.S. Pat. 829,676, Aug. 28, 1906.

The furnace (see figure) has its roof formed with straight portions inclined in opposite directions, and united by a

"rampant" arch, the inclination of one of the straight portions being greater than that of the other. The lines of the arch merge into the lines of the straight portions, and the inclination of the arch is towards the front of the furnace.—A. S.

Furnace; Roasting and volatilising ——. S. I. Clawson, Salt Lake City, Utah. U.S. Pat. 829,843, Aug. 28, 1906.

The furnace comprises a muffle fixed in and extending through a revolving cylinder mounted in an inclined position. Between the muffle and the cylinder are "fire chambers" (heating chambers) communicating with a fire-box at the lower end of the cylinder. The upper end of the muffle communicates with a vertical "fume-pipe," and there is also a stationary chimney or smoke-stack, from which a longitudinal branch extends above the cylinder for its entire length. The ore is fed into and conveyed through this branch of the stack, and then falls down a shoot into a conveyor, which passes transversely through the fume-pipe, and extends into the muffle. The branch of the stack also contains a nest of air-superheating pipes, the air from which is forced by a fan into the fuel-feeding device, which delivers powdered coal to the fire-box. There are also longitudinal air-superheating pipes disposed in the wall of the cylinder, communicating with a coiled pipe surrounding the fire-box, the coil being connected to a blast-pipe which delivers the hot air into the lower end of the muffle.—A. S.

Furnace; Matte-producing ——. R. Baggaley, Pittsburg, Pa. U.S. Pat. 830,039, Sept. 4, 1906.

The invention relates to a furnace for producing copper matte or copper, and consists in constructing the wall of the furnace in adjustable water-cooled sections, one of which carries a slag-spout.—A. S.

Blast furnace. M. Mannaberg, Assignor to Frodingham Iron and Steel Co., Frodingham. U.S. Pat. 830,513, Sept. 11, 1906.

See Eng. Pat. 26,263 of 1905; this J., 1906, 319.—T.F.B.

Furnace for roasting, chloridising [chlorinating], or drying ores. A. V. Leggo, Pendeen, Victoria. U.S. Pat. 830,904, Sept. 11, 1906.

See Eng. Pat. 21,160 of 1905; this J., 1906, 591.—T.F.B.

Sulphurous oxide [Sulphur dioxide]; Process of recovering——[from furnace gases]. F. R. Carpenter, Denver, Colo. U.S. Pat. 829,765, Aug. 28, 1906.

The gases from furnaces burning sulphide ores are moistened with cold water, and caused to deposit suspended particles of solid matter, and the sulphurous oxide (sulphur dioxide) in the gases is recovered by absorption in water cooled to about 0° C.—A. S.

Ores; Method of smelting ——, and separating mattes. R. Baggaley, Pittsburg, Pa., C. M. Allen, Lo Lo, Mont., and E. W. Lindquist, Chicago, Ill. U.S. Pat. 830,040, Sept. 4, 1906.

A body of molten matte is formed in a converter, and air is blown through. Sulphide ore is then fed in at one end of the converter, and allowed to float on the molten matte in the direction of the other end, being oxidised and melted during its travel, by the heat produced by the converting action. The resulting slag and matte overflow continuously at the axis of the converter, and are protected from the chilling effect of the atmosphere during their travel from the converter to a fore-hearth or settling chamber, wherein they are separated by gravity.—A. S.

Crucible. E. A. Colby, Newark, N.J. U.S. Pat. 830,208, Sept. 4, 1906.

The claim is for a lining of friable material which is applied in sections or otherwise to the inner face of the inner side of an annular crucible. It is formed so as to be less resistant to internal pressure than the material of the crucible, in order that the latter may not be fractured by the expansive force of the solidifying metal.—W. H. C.

Zinc; Apparatus for obtaining ——. J. Armstrong, London. U.S. Pat. 830,283, Sept. 4, 1906.

See Eng. Pat. 20,543 of 1905; this J., 1905, 1113.—T.F.B.

Silicon; Method of melting and casting ——. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 830,738, Sept. 11, 1906.

The silicon is fused in a vessel of carbon, the temperature being kept too low to form silicon carbide. The molten silicon is cooled in a suitable mould.—E. S.

French Patents.

Volatile minerals; Recovery and utilisation of heat lost in the condensation of metallic dust from roasting ——. See Anon. des Mines et Usines d'Antimoine de Brioude-Auvergne. Fr. Pat. 361,530, Dec. 21, 1905.

By means of an arrangement of cooling tubes, each open at one end to the air, whilst the other end opens into a common channel, through which air is supplied to the furnace, the heat abstracted from the volatilised substances is utilised in the roasting furnace.—J. H. C.

Metals and alloys; Production of fused —— by means of their oxides and other compounds. Weldite, Ltd. Fr. Pat. 364,949, Feb. 24, 1906.

See Eng. Pat. 10,881 of 1905; this J., 1906, 763.—T.F.B.

Furnaces; Regenerative ——, with arrangement for regulating the firing. Bethlehem Steel Co. Fr. Pat. 364,240, March 14, 1906.

The furnace proper is built over regenerative chambers which are supplied with air and gas; these having become heated in their passage through the chambers are allowed

to mix in a conduit whence they pass into the furnace-chamber through a series of orifices—the spent gases being finally allowed to escape to the chimney through a similar series of orifices, the whole circulation being controlled by valves so arranged as to reverse the currents when desired.—J. H. C.

Thermic process, based on the action of silicon combined with magnesium or its compounds. T. Goldschmidt. Fr. Pat. 364,313, March 16, 1906.

This process is based on the mutual reaction of oxides or sulphides of metals, or of metallic compounds and halogen substances, or of combinations of such bodies with each other when mixed with a reducing agent consisting of a mixture, or alloy, of magnesium and silicon, all the substances being employed in a finely divided or granulated condition. Such mixture is analogous to "aluminothermite," which forms the basis of the "Goldschmidt's process," wherein aluminium acts as the reducing agent.
—J. H. C.

Copper and other metals; Extraction of —— from burnt pyrites residues. A. Tixier. Fr. Pat. 364,512, March 23, 1906.

The residues are treated with nascent chlorine in an acid solution at a temperature of from 70° to 80° C., whereby the copper and other metals are brought into solution for subsequent treatment by known methods.

The nascent chlorine is obtained from chloride of lime, or alkali or alkaline-earth hypochlorites. The dry burnt pyrites residues may, for example, be treated with from 2 to 5 per cent. of chloride of lime, and then, in the vats, the mixture is treated with dilute hydrochloric acid.
—J. H. C.

Minerals; Process and apparatus for the reduction or fusion of —— by means of carbon monoxide. E. A. A. Grönwall. Fr. Pat. 365,412, April 19, 1906. Under Int. Conv., May 8, 1905.

See Eng. Pat. 9799 of 1906; this J., 1906, 850.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 892.)

(*A.*)—ELECTRO-CHEMISTRY.

Paper and solid cellulose [and acetylcellulose]; Electrical insulating properties of dry ——. A. Campbell. Proc. Roy. Soc., 1906, 78A, 196—211.

The results of experiments on a number of papers used for insulating telephone wires are given. All the papers were of "chemical wood fibre," this kind being considered the most durable. For telephonic purposes a minimum of specific inductive capacity is desirable; this constant ranged from 1·8 to 2·5 (air = 1) in the papers examined, after thorough drying, and was found to be approximately proportional to the density. The best material is that which contains the greatest proportion of air spaces, and in which the fibres lie as much as possible parallel to the surface.

For transparent films of pure cellulose the specific inductive capacity was found to be about 7, for normal cellulose triacetate about 3·9. The latter material is far less susceptible to temperature changes, as regards electrical properties, than cellulose. Cellulose as an insulator is very greatly affected by minute amounts of moisture, and the author's experiments on this point lead to the inference that in air-dried material a part of the moisture is chemically combined with cellulose to form an electrolytic solution, possibly of water in cellulose hydrate. When the temperature is raised, dissociation takes place, and an altered equilibrium between cellulose and water is eventually attained.—W. A. C.

Reduction processes; Rôle of metal hydrides in ——, and new data as to the composition of certain fats and fish oils. S. Fokin. J. russ. phys.-chem. Ges., 1906, 38, 419—446. Chem. Centr., 1906, 2, 758—759.

It has been stated by Marie (Compt. rend., 136, 1331; also this J., 1903, 1003) and Petersen (Z. Elektrochem., 11, 549; also this J., 1905, 895) that, in the electrolytic reduction of unsaturated acids, the nature of the cathode used has no appreciable influence upon the course and velocity of the reaction. The author finds, however, that reduction can only be effected with cathodes of palladium, platinum, rhodium, ruthenium, iridium, osmium, nickel, cobalt, and copper, and that the quantity and the physical condition of the metal has a considerable influence on the course of the reduction. It is known that the metals named have the capacity of occluding hydrogen, with the formation of unstable hydrides. It is these metals, also, which have been found to act as hydrogen-carriers in the reduction processes studied by Sabatier and Senderens (this J., 1901, 978; 1902, 504, 566, 1070, 1157; 1903, 1012; 1904, 341, 654). The author is of the opinion that all reduction processes taking place in presence of the metals mentioned, *viz.*, electrolytic reduction, reduction of gaseous substances by reduced metals by the process of Sabatier and Senderens, reduction by galvanic couples, and reductions by metal hydrides in solutions, are due to a special activity of the occluded hydrogen, probably owing to such hydrogen being in the monatomic condition. The activity of the metals varies directly with their capacity of occluding hydrogen; palladium is the most efficient, and then follow, in the order given, platinum, nickel, cobalt, and copper. The best results are obtained by the electrolytic process, and the author has studied in this way the reduction of the fatty acids from linseed oil, Japanese wood oil, castor oil, and cod-liver oil, other unsaturated acids, allyl alcohol, nitrobenzene, and carbon tetrachloride. He finds that linseed oil contains besides linolenic acid, an isomeride of linolic acid, which does not form a crystalline tetra-bromo-derivative. The elæomargaric acid from Japanese wood oil contains 18, not 17, carbon atoms, and appears to be an isomeride of linolic acid. The hydroxystearic acid from castor oil is identical with the acid described by Kojanski (J. russ. phys.-chem. Ges., 32, 149). Cod-liver oil contains fatty acids with from 18 to 21 carbon atoms. Carbon tetrachloride is reduced to chloroform, and also, in part, to methylene dichloride and methyl chloride.—A. S.

Voltaic strong-current arcs; Production of ——. H. Pauling, Gelsenkirchen, Germany. Eng. Pat. 7869, April 2, 1906.

In order to produce voltaic strong-current arcs between electrodes comparatively distant from each other, the discharges of an auxiliary spark-gap are blown into the space between the electrodes. The horn-shaped electrodes between which the arc is to be struck are connected by wires to a source of electrical energy. In parallel with this main spark-gap is arranged the primary coil of a transformer, the secondary coil of which is connected to an auxiliary pair of electrodes disposed below and in the same plane as the main electrodes. The two pairs of electrodes are contained in a pipe of oval cross-section, through which a current of gas is blown at a velocity of at least 50 metres per second. The discharge between the auxiliary electrodes is blown by the current of gas between the main electrodes, and allows the electrical energy supplied to the latter to jump across the spark-gap.—A. S.

United States Patents.

Furnace; Electric ——. B. Platschick, Paris. U.S. Pat. 826,962, July 24, 1906.

This invention relates to an electric muffle, consisting of a receptacle of fire-proof material and a casing into which the receptacle fits. The casing is provided with a bottom and fixed vertical walls, together with a movable vertical side wall which is pivoted at its lower edge to the bottom, and a top or lid pivoted to the upper edge of the movable wall. In the wall of the receptacle is secured a heating conductor, the latter being connected to two contact pieces projecting from the lateral wall of the receptacle, and passing through apertures in the casing. When the receptacle is placed in position in the casing, the contact pieces engage with spring contacts fixed to a bed-plate which carries the casing. In the back of the receptacle, is an opening, through which is placed a thermo-electric couple, one end of the latter projecting into the heated portion of the furnace. Resistance wires, housed in the wall of the receptacle, are attached to the rear end of the couple, the couple and resistance wires being protected against the influence of the temperature at the outside of the apparatus by a "heat-repelling pad." Rods are connected to the resistance wires, and project outside the receptacle, so that connection may be made with a suitable galvanometer.—B. N.

Filament; [Electric] Incandescent lamp ——, *and method of making the same.* J. M. Canello. U.S. Pat. 829,568, Aug 28, 1906. II., page 919.

Cotton; [Electrolytic] Method of treating ——. G. D. Burton. U.S. Pat. 827,293, July 31, 1906. V., page 925.

Gases; [Electrical] Method of effecting chemical action in ——. D. R. Lovejoy, Assignor to Atmospheric Products Co., Niagara Falls, N.Y. U.S. Pat. 829,872, Aug. 28, 1906.

This invention relates to a method of causing gases to unite chemically, and consists in charging the gases separately with electrostatic charges of different polarity, and of a potential sufficient to effect chemical combination. When the gases are mixed, the electrostatic attraction of the molecules of one gas for the molecules of the other gas will cause combination of the gases.—B. N.

Gases; Apparatus for subjecting —— *to high-tension [electrical] discharges.* D. R. Lovejoy, Assignor to Atmospheric Products Co., Niagara Falls, N.Y. U.S. Pat. 829,873, Aug. 28, 1906.

The apparatus comprises a chamber for receiving the gases, a series of fixed electrodes mounted adjustably in the walls of the chamber, and a series of movable electrodes, both sets being connected in parallel with a high-tension alternating current. In order to ensure a minimum volume and minimum current for each of the arcs, each of the parallel electrode circuits is provided with an inductance, and the electrodes are constructed of fine wire. The movable electrodes are fixed to the ends of supports carried by a shaft capable of rotation, the shaft being provided with insulated bearings. As the shaft turns, the movable electrodes come within arcing distance of the fixed electrodes, and the arcs are successively formed, elongated, and extinguished. The arc formed between any pair of electrodes is isolated by suitable means from the arcs formed between adjacent pairs of electrodes. A synchronous motor, mounted on, but insulated from, the chamber, is connected to the generator, and drives the movable electrodes, means being provided for adjusting the making and extinction of the arcs relatively to the alternation and phase of the alternating current. A rectifier, in the alternating current circuit, with its commutator moving with the movable electrodes, is arranged so as to cause reversals of current during extinction of the arcs, whereby the same potential relation between the electrodes is maintained. The gases are supplied to the central portion of the chamber at a pressure higher than that of the atmosphere, and the gases receive an outward spiral motion. Outlets for the products are arranged in close proximity to the arcing points, and each outlet is provided with a deflector, directed contrary to the direction of rotation of the shaft, so as to deflect the products formed by the arcs into the outlets. Gas-ducts, leading from the outlets, are provided with valves, which are intermittently opened and closed by suitable means, thus giving an intermittent flow of gases into the chamber, the impulses of flow being timed to commence just after the arcs are struck, and to cease just after the arcs are extinguished. The gases may be separately charged electrostatically before being led into the chamber, and allowed to mix in the presence of the arcs, or immediately before coming into contact with the arcs.—B. N.

Gases; [Electrical] Method of effecting the combination of ——. D. R. Lovejoy, Assignor to Atmospheric Products Co., Niagara Falls, N.Y. U.S. Pat. 829,874, Aug. 28, 1906.

This invention relates to a process of forming nitrogen compounds, an electric arc or arcs being formed, elongated, and interrupted, and a mixture of air and oxygen, containing about equal volumes of nitrogen and oxygen, being introduced into the presence of the arc. The residual gas may be again treated after enriching with oxygen. Hydrogen may also be added, so as to form a mixture containing less than 10 per cent. of hydrogen.—B. N.

Gases; [Electrical] Apparatus for effecting chemical action in ——. D. R. Lovejoy, Assignor to Atmospheric Products Co., Niagara Falls, N.Y. U.S. Pat. 829,875, Aug. 28, 1906.

A suitable reaction chamber is provided with one outlet and two inlet-passages for supplying gases, the latter passages being provided with electrodes. Electrostatic charges of opposite potential are given to the electrodes, which thus impart similar charges to the gases. Means are provided for heating the electrodes, and for subjecting the gases to the influence of a source of radiant energy.
—B. N.

Gases; [Electrical] Process and apparatus for effecting chemical action in ——. D. R. Lovejoy, Assignor to Atmospheric Products Co., Niagara Falls, N.Y. U.S. Pats. 829,876 and 829,877, Aug. 28, 1906.

The molecules of the gases, such as nitrogen and oxygen, are separately charged electrostatically to opposite potentials, and the gases mixed, and subjected to the action of an electric current in the form of an arc of minimum volume. The arc is maintained at a minimum volume, sufficient to prevent the breaking of the arc, or the latter may be repeatedly formed, elongated, and interrupted.—B. N.

Ozonised air or oxygen; Apparatus for producing highly ——. A. Déchaux, Paris, Assignor to W. Mallmann, Ruremonde, Holland. U.S. Pat. 830,975, Sept. 11, 1906.

See Fr. Pat. 335,092 of 1903; this J., 1904, 193.—T. F. B.

French Patents.

Incandescence lamps; Process of increasing the electric resistance of certain metals, especially those used for glow-bodies of ——. H. Kuzel. Fr. Pat. 364,613, March 27, 1906. II., page 920.

Glow-bodies for electric lighting; Manufacture of ——. Siemens and Halske, A.-G. Fr. Pat. 364,925, April 5, 1906. II., page 920.

Sugar from molasses; Process of extracting —— *by the aid of a new compound.* R. Battistoni and R. Rotelli. Fr. Pat. 364,689, Jan. 6, 1906. XVI., page 944.

to mix in a conduit whence they pass into the furnace-chamber through a series of orifices—the spent gases being finally allowed to escape to the chimney through a similar series of orifices, the whole circulation being controlled by valves so arranged as to reverse the currents when desired.—J. H. C.

Thermic process, based on the action of silicon combined with magnesium or its compounds. T. Goldschmidt. Fr. Pat. 364,313, March 16, 1906.

This process is based on the mutual reaction of oxides or sulphides of metals, or of metallic compounds and halogen substances, or of combinations of such bodies with each other when mixed with a reducing agent consisting of a mixture, or alloy, of magnesium and silicon, all the substances being employed in a finely divided or granulated condition. Such mixture is analogous to "aluminothermite," which forms the basis of the "Goldschmidt's process," wherein aluminium acts as the reducing agent.
—J. H. C.

Copper and other metals; Extraction of —— from burnt pyrites residues. A. Tixier. Fr. Pat. 364,512, March 23, 1906.

The residues are treated with nascent chlorine in an acid solution at a temperature of from 70° to 80° C., whereby the copper and other metals are brought into solution for subsequent treatment by known methods.

The nascent chlorine is obtained from chloride of lime, or alkali or alkaline-earth hypochlorites. The dry burnt pyrites residues may, for example, be treated with from 2 to 5 per cent. of chloride of lime, and then, in the vats, the mixture is treated with dilute hydrochloric acid.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 892.)

(*A.*)—ELECTRO-CHEMISTRY.

Paper and solid cellulose [and acetylcellulose]; Electrical insulating properties of dry ——. A. Campbell. Proc. Roy. Soc., 1906, 78A, 196—211.

The results of experiments on a number of papers used for insulating telephone wires are given. All the papers were of "chemical wood fibre," this kind being considered the most durable. For telephonic purposes a minimum of specific inductive capacity is desirable; this constant ranged from 1·8 to 2·5 (air = 1) in the papers examined, after thorough drying, and was found to be approximately proportional to the density. The best material is that which contains the greatest proportion of air spaces, and in which the fibres lie as much as possible parallel to the surface.

For transparent films of pure cellulose the specific inductive capacity was found to be about 7, for normal cellulose triacetate about 3·9. The latter material is far less susceptible to temperature changes, as regards electrical properties, than cellulose. Cellulose as an insulator is very greatly affected by minute amounts of moisture, and the author's experiments on this point lead to the inference that in air-dried material a part of the moisture is chemically combined with cellulose to form an electrolytic solution, possibly of water in cellulose hydrate. When the temperature is raised, dissociation takes place, and an altered equilibrium between cellulose and water is eventually attained.—W. A. C.

Reduction processes; Rôle of metal hydrides in ——, and new data as to the composition of certain fats and fish oils. S. Fokin. J. russ. phys.-chem. Ges., 1906, 38, 419—446. Chem. Centr., 1906, 2, 758—759.

It has been stated by Marie (Compt. rend., 136, 1331; also this J., 1903, 1003) and Petersen (Z. Elektrochem., 11, 549; also this J., 1905, 895) that, in the electrolytic reduction of unsaturated acids, the nature of the cathode used has no appreciable influence upon the course and velocity of the reaction. The author finds, however, that reduction can only be effected with cathodes of palladium, platinum, rhodium, ruthenium, iridium, osmium, nickel, cobalt, and copper, and that the quantity and the physical condition of the metal has a considerable influence on the course of the reduction. It is known that the metals named have the capacity of occluding hydrogen, with the formation of unstable hydrides. It is these metals, also, which have been found to act as hydrogen-carriers in the reduction processes studied by Sabatier and Senderens (this J., 1901, 978; 1902, 504, 566, 1070, 1157; 1903, 1012; 1904, 341, 654). The author is of the opinion that all reduction processes taking place in presence of the metals mentioned, *viz.*, electrolytic reduction, reduction of gaseous substances by reduced metals by the process of Sabatier and Senderens, reduction by galvanic couples, and reductions by metal hydrides in solutions, are due to a special activity of the occluded hydrogen, probably owing to such hydrogen being in the monatomic condition. The activity of the metals varies directly with their capacity of occluding hydrogen; palladium is the most efficient, and then follow, in the order given, platinum, nickel, cobalt, and copper. The best results are obtained by the electrolytic process, and the author has studied in this way the reduction of the fatty acids from linseed oil, Japanese wood oil, castor oil, and cod-liver oil, other unsaturated acids, allyl alcohol, nitrobenzene, and carbon tetrachloride. He finds that linseed oil contains besides linolenic acid, an isomeride of linolic acid, which does not form a crystalline tetra-bromo-derivative. The elæomargaric acid from Japanese wood oil contains 18, not 17, carbon atoms, and appears to be an isomeride of linolic acid. The hydroxystearic acid from castor oil is identical with the acid described by Kojanski (J. russ. phys.-chem. Ges., 32, 149). Cod-liver oil contains fatty acids with from 18 to 21 carbon atoms. Carbon tetrachloride is reduced to chloroform, and also, in part, to methylene dichloride and methyl chloride.—A. S.

Voltaic strong-current arcs; Production of ——. H. Pauling, Gelsenkirchen, Germany. Eng. Pat. 7869, April 2, 1906.

In order to produce voltaic strong-current arcs between electrodes comparatively distant from each other, the discharges of an auxiliary spark-gap are blown into the space between the electrodes. The horn-shaped electrodes between which the arc is to be struck are connected by wires to a source of electrical energy. In parallel with this main spark-gap is arranged the primary coil of a transformer, the secondary coil of which is connected to an auxiliary pair of electrodes disposed below and in the same plane as the main electrodes. The two pairs of electrodes are contained in a pipe of oval cross-section, through which a current of gas is blown at a velocity of at least 50 metres per second. The discharge between the auxiliary electrodes is blown by the current of gas between the main electrodes, and allows the electrical energy supplied to the latter to jump across the spark-gap.—A. S.

Olive marc; Extraction of —— with carbon bisulphide or carbon tetrachloride. R. Jürgensen. Z. angew. Chem., 1906, 36, 1546—1547.

THE residues left after the extraction of oil from olives by pressure contain from 10 to 16 per cent. of oil, which is usually recovered by means of volatile organic solvents, such as ether, benzine, and especially carbon bisulphide. Carbon tetrachloride may be used advantageously in place of carbon bisulphide, as it is now obtainable at a moderate price. It is non-inflammable and leaves no odour in the oil.—H. B.

Herring oil; Japanese ——. C. E. Sage. Chem. and Drug., 1906, 69, 398.

A SAMPLE of Japanese herring oil examined by the author gave the following results:—Colour, pale brown; sp. gr. at 20° C., 0·9116; acid value, 16·8; saponification value, 193·7; iodine value, 137·0. (See also this J., 1906, 819.) —A. S.

Fatty substances; Saponification of ——. A. Haller. Fr. Pat. 361,552, June 13, 1905.

THE process claimed is for the simultaneous saponification of oils or fats and esterification of the fatty acids, by treating the fats, &c., with pure or concentrated alcohols and a small quantity of an acid such as hydrochloric acid, preferably on a hot water bath, under a reflux condenser. The resulting esters are separated from the glycerol and excess of the alcohol by treatment with cold water or salt water, and then isolated from one another by rectification, filtration, &c.—C. A. M.

Olive and other vegetable oils; Process of extracting ——. Don Miguel del Prado y Lisboa. Fr. Pat. 365,187, April 12, 1906.

THE entire olives or other fruit are introduced into a closed vessel surrounded by a hot water chamber, and provided with a mechanical agitator, and the oil liberated at a low temperature (20° C. at most) is drawn off below through filtering material by means of a vacuum pump. The temperature of the pulp is then raised to, say, about 50° C., and a second quality of oil drawn off through a filter into a second receptacle. Finally steam is blown into the vessel, and the supernatant oil drawn off through a pipe at the top, yielding oil of the third class. The olive stones separated from the residual pulp can be utilised in the manufacture of alcohol, acetic acid, &c., by destructive distillation, whilst the fruit pulp itself can be used as food for cattle. Special claim is made for a form of apparatus in which the above-described method of separating the oil can be carried out.—C. A. M.

Lubricating oil which emits no odour, or even has an agreeable odour on burning. A. Haenflein and L. Kornfeld. Fr. Pat. 365,335, April 17, 1906.

CLAIM is made for an addition to ordinary lubricating oil of substances which give off a pleasant odour on burning, and have a boiling point lower than that of the oil itself. Suitable substances mentioned are oil of mirbane, "*huile de terpine* ($C_{10}H_{18}O$)," and salicylic aldehyde.—C. A. M.

Wax; Method of bleaching ——. E. Weingärtner. Fr. Pat. 365,355, April 17, 1906.

THE crude substance (beeswax, carnäuba wax, &c.) is heated above its melting point, and treated with about 10 per cent. of fullers' earth, which is added little by little. The temperature is then gradually raised and maintained at, say, 150°—170° C., until the wax is bleached, after which the fullers' earth and impurities are separated by filtration, and the wax left in the residue subsequently extracted by means of a solvent.—C. A. M.

Detergent for use with hard or saline waters. R. Macpherson and W. E. Heys. Fr. Pat. 364,975, April 6, 1906. Under Int. Conv., Nov. 16, 1905.

A SOAP is prepared by treating cocoanut olein and a suitable albuminoid substance, preferably finely powdered cocoanut pulp, at a high temperature with a sufficient quantity of caustic alkali to effect saponification. Flour or other filling material can be added to the ingredients before saponification. It is claimed that the product is cheap, that it is easily soluble in hard and sea water, that it does not leave any odour, and that the small quantity of insoluble soap which it leaves on clothes, &c., is easily removed by rinsing.—C. A. M.

ENGLISH PATENTS.

Paints or compounds; Anti-corrosive ——. A. Milburn, trading as the Firsoline Manufacturing Co., East Sunderland, Durham. Eng. Pat. 18,683, Sept. 15, 1905.

A PREPARATION specially intended for metallic surfaces is made by incorporating oils, tallow, rosin, or the like with a mineral colour, such as zinc white, and an inert substance such as plaster of Paris. The ingredients and proportions specially claimed are as follows:—Fir or pine oil, 25; zinc white, &c., 15; plaster of Paris, 10; Archangel or Stockholm tar, 5; a resin, preferably Kauri, 10; and tallow, 35 per cent.—C. A. M.

Colour lakes [from azo dyestuffs]; Manufacture of ——. O. Imray, London. From Meister, Lucius, und Brüning, Hoechst-on-the-Maine, Germany. Eng. Pat. 27,252, Dec. 30, 1905.

THE patent relates to the preparation of colour lakes from the azo dyestuffs obtained by combining diazo compounds with the β-hydroxynaphthoic acid melting at 216° C. The free azo-carboxylic acids are treated at a high temperature with one or more alkaline-earth salts of a feeble acid (fatty or resin acids), or the sodium salt of the azo-carboxylic acid is treated with a soluble alkaline-earth salt in presence of one or more alkaline-earth salts of a weak acid. For example, 100 parts of white, finely ground heavy-spar are well stirred with 250 parts of water, and 23·47 parts of a paste containing 20 per cent. of *p*-nitrobenzene-azo-β-hydroxynaphthoic acid, diluted with 250 parts of water, are stirred in. Then, whilst stirring is continued, 3·2 parts of calcium chloride dissolved in 64 parts of water, 2·4 parts of sodium carbonate dissolved in 48 parts of water, and 2·5 parts of Turkey red oil (50 per cent.) in 25 parts of water, are added, and the whole is boiled until the shade no longer changes.—A. S.

White lead; Apparatus for producing ——. J. W. Bailey, Jersey City, N.J., Assignor to United Lead Co., New Jersey. U.S. Pat. 830,196, Sept. 4, 1906.

THE apparatus comprises a corroding chamber fitted with overlapping shelves disposed one above the other. An endless chain moves over the shelves in succession, and is provided with cross-bars to which are pivoted rows of ploughs, "placed alternately in reversed positions." The movement of the chain operates mechanism for feeding comminuted lead to the top shelf, and for supplying a limited amount of moisture to the lead. By means of the ploughs the lead on the shelves is continually turned over, and moved along the shelves and from one shelf to the next lower one, at a rate slower than the movement of the chain. Means are provided for supplying a corroding gas to the chamber.—A. S.

Paint. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg. U.S. Pat. 830,737, Sept. 11, 1906.

Wood distilling and preserving apparatus [for extraction of turpentine, &c.]. F. S. Davis, Mulligan, S.C. Assignor to J. C. Richardson, Robertsville, S.C. U.S. Pat. 826,407, July 17, 1906.

THIS invention relates to an apparatus for treating wood with a heated fluid, such as melted rosin, the latter extracting turpentine and other light volatile oils without injuring the texture of the wood. The material to be treated is placed in a retort, or battery of retorts, a valved branched supply pipe connecting each of the retorts with a centrifugal pump located at or near the bottom of a tank. The latter is heated by a suitable furnace for melting down the material used as a distilling fluid, and the fluid is thoroughly agitated, and discharged from the tank to the retorts by the pump. A valved gravity discharge pipe connects each retort with the tank. The distilling fluid is maintained at an even temperature after being charged into a retort, by circulating it through a reheater and back to the retort by means of a second pump.—B. N.

Turpentine; Process for clarifying and deodorising oil of wood ——. E. Heber, New York. U.S. Pat. 830,069, Sept. 4, 1906.

TARRY matters are removed from oil of wood turpentine by distillation over lime, and the purified oil is emulsified with soap solution; the emulsion is treated with oxidising agents to oxidise the colouring matters and odoriferous substances, the soap is precipitated, and the product distilled with steam, the purified turpentine oil being subsequently separated from the water.—T. F. B.

FRENCH PATENT.

Resins; Process for obtaining transparent synthetic —— to be used as substitutes for natural resins. Fabr. de Prod. de Chim. Organ. de Laire. Fr. Pat. 361,839, June 8, 1905.

TRANSPARENT synthetic resins, which can be used in place

of copal, amber, shellac, &c., are prepared by condensing commercial phenol or its homologues with formaldehyde or its homologues, and heating the condensation product in the air, under pressure, or *in vacuo*. For example, 10 parts of phenol are treated with 5—10 parts of a 40 per cent. solution of formaldehyde and about 10 parts of 15 per cent. hydrochloric acid. The product is washed free from acid and excess of phenol, and the resulting plastic mass is heated for about half an hour at 140° C., either in the air or in presence of an inert gas under pressure, when a hard, transparent, yellow resin, resembling amber, is obtained.—A. S.

(*C.*)—INDIA-RUBBER, &c.

India-rubber latex; Physical chemistry of ——. V. Henri. Gummi-Zeit., 1906, **20**, 1227—1229.

The latex of *Hevea brasiliensis* is faintly alkaline, and contains 8·7 per cent. of total solids. In one cubic millimetre there are 50 millions of microscopically visible globules, which show well-marked Brownian movement, but can be brought to rest by dilution with at least 500 volumes of 20 per cent. brine. Latex which has been freed from salts, &c. by dialysis, may by suitable reagents be either precipitated in flocculent particles or coagulated to a clot, the latter phenomenon being experimentally proved to be merely an advanced stage of the former. Alcohols have no effect on dialysed latex; neither have alkalis and salts of univalent metals. Salts of the alkaline earths, in at least N/1 concentration, and salts of the heavy metals as dilute as N/20, precipitate but do not coagulate. Acids are precipitants, sulphuric acid being especially active and causing coagulation in moderate dilution. Trichloracetic acid, even dilute, and acetone, are coagulants. Coagulation is readily brought about by mixtures of alcohol with very small proportions of bivalent salts or of acids, whilst alkalis have an inhibitory influence.—W. A. C.

Latex of Kickxia (Funtumia) elastica. H. Strunk. Ber. Dtsch. pharm. Ges., 1906, **16**, 214—226. Chem. Centr., 1906, **2**, 689.

Specimens of the latex of *Kickxia elastica* were obtained from cuts in the barks (1) 20 cm. and (2) 2½ m. above the ground, (3) from cuts in thin branches 4 m. above the ground, and (4) from leaf-stalks. These contained respectively: (1), 49·09; (2), 44·17; (3), 35·38; and (4) 52·02 per cent. of dry substance; and (1), 44·84; (2), 35·94; (3), 22·84; and (4), 44·94 per cent. of pure caoutchouc. The percentage of caoutchouc in the latex thus appears to decrease as the distance of the cut above the ground increases. In Kamerun, the natives coagulate the latex by mixing it with one-half or one-third of its volume of water, and boiling in an earthenware vessel. Coagulation can, however, be effected without boiling by pouring the latex into five times its volume of water, and vigorously agitating the mixture. An addition of 1 c.c. of 25 per cent. hydrochloric acid retards the coagulation of the caoutchouc by boiling; an addition of 3 c.c. of 32 per cent. hydrochloric acid, on the other hand, so accelerates the process that coagulation takes place at 45°—50° C.; the caoutchouc obtained in this manner shows less tendency to decompose than that obtained in other ways. The average specific gravity of the latex was 0·9961 at 28° C., and the average content of dry substance, 46·88 per cent., with 0·806 per cent. of ash. The freshly coagulated rubber contains 5·31—7·41 per cent. of resin. On keeping, the rubber softens somewhat owing to oxidation, the proportion of caoutchouc decreasing and that of resin increasing. The author recommends collecting the latex from long, vertical incisions in the tree.—A. S.

Latex of Dyera costulata. W. A. Tilden. Brit. Assoc., Section B, York, 1906. Chem. News, 1906, **94**, 102.

The sample of the latex of *Dyera costulata* examined by the author contained a small quantity of ammonia, which had been added to prevent coagulation. It was a white creamy liquid of sp. gr. 1·11, miscible with water. It is coagulated, sooner or later, by all acids, and on vigorous agitation the suspended particles unite to form lumps. It is also coagulated by strong brine, and by warming with an equal volume of a 20 per cent. solution of sodium carbonate. When heated to 70°—80° C., a skin forms on the surface. The latex yielded about 44 per cent. of solid matter when coagulated by hydrochloric acid; the coagulum was tough, but contained very little rubber substance, being almost completely soluble in alcohol and in acetone.

Pontianak, which is stated to be obtained from *Dyera costulata*, contains a small quantity of caoutchouc mixed with two or more other substances, of which one, melting at 173° C., can be crystallised from alcohol. The crystals contain 81·2 per cent. of carbon and 11·0 per cent. of hydrogen, corresponding approximately to the formula, $C_{14}H_{22}O$. The molecular weight, as determined by the freezing-point method, was, however, about 322, as compared with 206 required by the formula given.—A. S.

Rubber; Sicilian ——. E. Marckwald and F. Frank. Gummi-Zeit., 1906, **20**, 1254—1255.

A sample of crude rubber prepared from the latex of *Ficus elastica* plants, grown in the Botanical Gardens, Palermo, was found to have the following composition:—

Moisture (loss at 100° C.), 1·51; mechanical organic impurities, 2·30; inorganic impurities, 1·75; resins, 22·19; and rubber substance, 72·29 per cent.

Although the change of habitat of the plant appears to have influenced the product detrimentally in the sense of increasing its resin-content, the crude rubber was yet of apparently good quality.

From a sample of the latex the authors obtained 38 per cent. of dry substance by coagulation.

A sample of a rubber-containing resinous product, obtained from *Abractylis gummifera L.*, indigenous to Sicily (*cf.* Landerer, Ueber den Akanthomastix des Orients. Buchners Repertorium, 1874, p. 437; Lefranc, Med. pharm. Botanik, 1883, p. 1105; Wiesner, Rohstoffe, 2nd Edition, Vol. I. p. 81, Vol. II. p. 495), was also examined and found to have the following composition:—

Moisture (loss at 100° C.), 4·24; mechanical organic impurities, 1·40; albuminoids, 4·07; inorganic impurities, 2·31; resins, 51·52; and rubber substance, 36·46 per cent.

The product has been stated to be used to adulterate mastic (Landerer, *loc. cit.*).—E. W. L.

Rubber industry of Brazil. For. Off. Ann. Series, No. 3713. [T.R.]

The development of the trade in seringa rubber is evident from the following figures, showing the exports from Brazil for the past five years:—

Year.	Quantity. Tons.	Value. £
1901	29,161	8,454,179
1902	27,177	7,052,586
1903	29,068	9,293,839
1904	28,505	10,515,877
1905	31,474	13,795,372

FRENCH PATENT.

Caoutchouc; Process for the manufacture of artificial ——. P. Beresfne. Fr. Pat. 365,047, April 9, 1906.

COD-LIVER oil or a vegetable oil, preferably that extracted from the flowers of the sunflower (*Helianthus annuus*), is treated with sulphur chloride (25 parts to 100 parts of oil). The mixture becomes hot, and when the temperature rises to 115° C. the action is stopped by cooling. The mass is then exposed to the air for at least 10 days, when an elastic, yellow substance, called "caoutchène," is obtained. This is cut into small pieces, dissolved in benzene, mixed with a solution of "matésite" in benzene, and isoprene added to the mixture. The product is freed from benzene by heating *in vacuo*. The "matésite" is obtained from the sticky juice of a plant of the *Apocyneæ* species, which grows in Madagascar. The juice is added to a 2 per cent. solution of sodium chloride, heated to 30° C. with agitation, for half an hour, the salt solution decanted off, the residue washed with cold water, and dried. The isoprene is prepared by treating fusel oil with fuming sulphuric acid whilst blowing a current of air through the liquid, filtering the resulting black mass, treating the filtrate with quicklime, and subjecting it to destructive distillation; isoprene begins to distil over at 117° C.

—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tannin; Determination of —— in tanning materials. Boudet. XXIII., page 956.

Seaweed industry of Japan. C. J. Davidson. XVIII*A*., page 948.

Chrome tanning industry of Madras. Bd. of Trade J., Sept. 13, 1906. [T.R.]

MR. A. CHATTERTON, Superintendent of Industrial Development, Chrome Tanning Department, Madras, reports on the results of the chrome tanning operations undertaken under his superintendence during the year ended 31st March. The following is extracted from Mr. Chatterton's report:—

"The output of chrome leather from the Chrome Tanning Department, Madras, has risen in value from Rs. 400 a month in 1904–05 to Rs. 2500 a month in 1905–06. . . . . Experience extending now to more than two years shows that the leather is well adapted to kavalais (for well irrigation), but that the price at which they can be manufactured in Madras is more than the ordinary ryot will pay. . . .

"The natural colour of the leather is a pale green or light lavender blue, and for boots, shoes, and harness it has to be dyed.

"The cost of manufacture of chrome leather is little greater than that of bark-tanned leather, but in order to turn out presentable chrome tanned leather, a superior class of hide or skin is required. In Madras only 'seconds' are suitable for this trade, and for these enhanced prices are asked, as the demand for them is considerable. . . .

"The goods certainly do not possess the finish of imported material, but they lack nothing in respect to strength and durability. . . . ."

Mr. Chatterton ascribes the failure of chrome leather to be adopted for the manufacture of kavalais for well irrigation to three causes, *viz.*:—

1. The fact that the purchase of raw skins from the market is itself a highly difficult art, in the technique of which his subordinates are just beginning to acquire experience;

2. The cost of the chrome-tanning process, which cannot be reduced unless operations are carried on on a much more extensive scale than is possible with the present limited demand for chrome-tanned leather and chrome leather articles; and

3. The fact that the price of chrome leather articles is prohibitive to the ordinary Indian purchaser, accustomed to cheap kavalais and to shoes and sandals made of country leather.

ENGLISH PATENTS.

Leather; Manufacture of ——. F. Kohl, Stuttgart, Germany. Eng. Pat. 14,602, June 26, 1906.

THE patent relates to an improved method of tanning hides. Two vats are used: after being treated in one vat, the hides are passed between pressure rollers, and then transferred to the other vat, these operations being repeated until the desired effect is produced. It is claimed that in this way the preliminary soaking of the hides is finished in one to two hours, the swelling and loosening of the hair in about two hours, and the actual tanning in about half an hour.—A. S.

Glutinous substance in a dry and neutral state; Method of obtaining a soluble —— from tang-acid. Soc. Franç. La Norgine, Paris. Eng. Pat. 9622, April 24, 1906. Under Int. Conv., May 23, 1905.

SEE Fr. Pat. 361,498 of 1905; this J., 1906, 897.—T. F. B.

UNITED STATES PATENT.

Plastic masses from casein, &c.; Manufacture of ——. L. Collardon, Leipsic, Germany. U.S. Pat. 830,493. Sept. 11, 1906.

SEE Fr. Pat. 359,073 of 1905; this J., 1906, 327.—T. F. B.

FRENCH PATENTS.

Tanning; Process of ——. M. Guigneux. Fr. Pat. 364,954, March 17, 1906.

THE skins are soaked in soft water for about 24 hours, scraped on the flesh side to remove fatty and other matters, and then soaked in soft water for from four to eight days, the water being renewed at least every 48 hours. They are next treated in succession in four baths of the following composition:—

Temperature.	Water.	Alum.	Sea salt.
	litres.	kilos.	kilos.
(1) 30° C.	100	50	37·5
(2) At 35° C., (3) at 40° C., and (4) at 45° C.	100	50	18·75

Whilst in these baths the skins are worked with the hands, turned over, and rubbed, to accelerate the penetration of the dissolved salts into the skin. The skins are afterwards treated again in baths of the same composition as those described, but with an interval of 7—8 days between each treatment, until they are sufficiently tanned. The tanned skins are finished by oiling on the flesh side with dégras. The process is stated to be very economical, and to leave unaltered the natural colour of the fur.—A. S.

Gelatin; Process for rendering —— iridescent. A. Lecocq née C. Mouton. Fr. Pat. 361,562, June 17, 1905.

THE gelatin is dissolved in water containing some ammonium bromide in solution (3—5 per cent. of the weight of the gelatin), and if the finished product is to be more or less opaque, zinc white or the like is added. The solution is poured on to glass plates in the usual manner to obtain sheets or films of gelatin, which after being dried, are soaked in a bath of alcohol or ether, or a mixture of the two, or in alcohol or ether to which has been added a small quantity of acetic acid or ammonia. The gelatin is then dried, and afterwards soaked in a solution of silver nitrate in 80 per cent. alcohol (2 grms. of silver nitrate per litre), with or without the addition of ether, and again dried. Instead of soaking the gelatin in the first bath of alcohol or ether, it may be moistened with water.—A. S.

Gelatin with a dull surface; Process for the manufacture of ——. A. Lecocq née C. Mouton. Fr. Pat. 361,563, June 17, 1905.

THE process consists in incorporating with the gelatin,

before forming it into sheets, a suitable proportion of starch (from 5 to 20 per cent. of the weight of dry gelatin). If the gelatin be then allowed to set on a surface of ground glass, both sides of the sheet are dull; if the mould be of smooth glass, the gelatin will have a bright surface on the side which has been in contact with the glass, but this can be made dull by moistening or soaking in water.—A. S.

Casein; Process for rapidly drying precipitated hydrated ——. J. Ricard and C. E. Riche. Fr. Pat. 364,635, March 27, 1906.

The process is based on the fact that at about 100° C. the hydrated casein is converted into a pasty mass. The moist casein is fed from a hopper between two drying cylinders rotating in opposite directions, and heated to 100°—110° C.; it forms a film on the surface of the cylinders, and is quickly dried; the dry casein is removed by scrapers. A modification is also claimed in which only one drying cylinder is used.—A. S.

Glue or size, and process of making the same. M. Bonnet. Fr. Pat. 365,285, April 14, 1906.

The size is prepared with suitable proportions of rosin, carbon bisulphide, cellulose, caustic soda, and water. For example, 2 parts of rosin, 5 parts of carbon bisulphide, 8 parts of cellulose, 30 parts of caustic soda solution at 20° B., and 55 parts of water yield an agglutinant suitable for the manufacture of briquettes, &c. If 115 parts of water be used, a product suitable as a distemper is obtained; with 227 parts of water, a size applicable in the manufacture of paper is obtained; whilst with 400 parts of water the resulting product is suitable as a finish for textiles.—A. S.

German Patents.

Plastic mass; Process for the preparation of a ——. A. Allers. Ger. Pat. 168,358, Feb. 23, 1904.

One hundred and thirty grms. of aniline hydrochloride are dissolved in 130 grms. of water, and 90 grms. of formalin (40 per cent. solution of formaldehyde) are added. The mixture becomes hot. It is well stirred, cooled to 40°—50° C., and a further 90 grms. of formalin added. After stirring, the mixture is allowed to cool, when it sets to a plastic mass.—A. S.

Plastic mass from ivory- or horn-cuttings; Process for the preparation of a ——. H. Foerster. Ger. Pat. 168,360, April 14, 1904.

Ivory- or horn-cuttings are softened by heating, mixed with a binding agent such as albumin, and with fibres of "wood wool," or crude vegetable fibres, and pressed. The fibrous material increases the strength of the mass, and imparts a marbled appearance to the finished product. —A. S.

XV.—MANURES, &c.

(*Continued from page* 898.)

Beetroot vinasse; Concentration of —— with regard to the production of manure. P. Kestner. XVII., page 946.

Artificial manures in Japan. For. Off. Ann. Series, No. 3700. [T.R.]

The demand for fertilisers in Japan is very active; the import still grows, while the home production increases, and yet prices continue to rise. The import is composed mainly of ammonium sulphate, oil-cake, and phosphates. The greater part of the sardines caught in Japanese waters, in value about £750,000 a year, are ultimately used as manure.

Guano, &c.; Licence to remove —— from Ashmore Islands. Bd. of Trade J., Oct. 4, 1906. [T.R.]

Tenders are invited for an exclusive licence from the Secretary of State for the Colonies to occupy the Ashmore Islands (lying off the coast of Western Australia, in Latitude 12 deg. 14 min. S., Longitude 123 deg. 6 min. E.) and to remove guano and other fertilising substances therefrom. Tenders should be on the basis of a fixed royalty per ton of guano removed, the sum payable in any one year not to be less than a fixed amount, whatever the quantity of guano removed during that year. The term of years for which a licence is desired should also be stated. Further information may be obtained at the Colonial Office, Downing Street, S.W.

Phosphate of lime in Algeria. For. Off. Ann. Series, No. 3712. [T.R.]

Phosphate of lime is found in such a great number of places in the province of Constantine, and is so easily worked, that it can be considered one of the first mineral resources of Algeria.

The principal beds in the province may be divided into four groups: (1) District of Tébessa; (2) district of Sétif; (3) district of Guelma; (4) district of Aïn-Beïda.

The rock phosphate extracted is of two qualities: No. 1 containing 63 to 70 per cent. of phosphate of lime; No. 2, 58 to 63 per cent.

The cost price of the phosphate on trucks at Tébessa station is about 4s. per ton. This includes extraction, drying, and transport from the mines to Tébessa. The cost of carriage from Tébessa to Bône, which is already very high according to the railway tariff—6s. 2d. per ton—is further increased by the necessity of transhipping the phosphate at Souk-Ahras from the narrow-gauge line of Tébessa into the trucks of the broad-gauge line between Souk-Ahras and Bône.

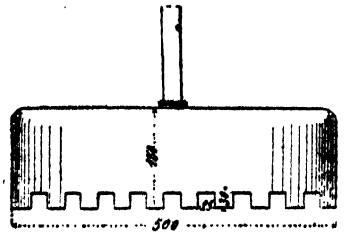
Altogether the cost of a ton of phosphate on quay at Bône is from 11s. to 12s.

French Patent.

Distillation residues of starchy matters [Vinasse]; Process for recovering ——. F. and E. D. Verbiese. Fr. Pat. 361,534, June 2, 1905. XVII., page 947.

XVI.—SUGAR, STARCH, GUM, &c.

(*Continued from page* 899.)



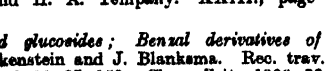
Sugar content of the beetroot and purity of diffusion juice as well as that of the massecuite obtained therefrom; Relation between ——. F. Sachs. Sixth Internat. Congr. Appl. Chem., Rome, 1906; Z. Ver. deut. Zuckerind., 1906. 827—838.

The author considers that too much importance is attached to the "coefficient of purity" of sugar juice, and prefers to value the latter by the estimation of the "coefficient of impurity," *i.e.*, the amount of foreign matter (non-sugar) per 100 parts of sugar in manufacturing products. Similarly, the "coefficient of salts" should be replaced by the "coefficient of ash," *i.e.*, the amount of inorganic matter per 100 parts of sugar. The difference between the coefficient of impurity and that of ash represents the amount of foreign organic matter per 100 parts of sugar. To find approximately the "true" coefficient of impurity, the author recommends the estimation of the apparent coefficient (deduced from the polarisation and the degrees Balling), the ratio between the apparent and the true coefficients of impurity being taken as 10:9.

Analytical results from a number of Belgian and Dutch sugar factories, obtained during 1892—1905, are tabulated and compared. In one series of tables the author has classified the results in three periods, 1892—1895, 1895—1901, 1901—1905, for the Belgian analyses, and 1892—1894, 1894—1900, 1900—1905, for the Dutch analyses. In both cases the percentage of sugar in the beetroot shows a progressive increase, and the impurity coefficient of the diffusion juice and also of the first product massecuite shows a progressive decrease. In both cases, also, the results show an improvement in the factory work; in the first period (1892—1895) 33 and 36 per cent. respectively of the foreign matter in the diffusion juice were removed during the preparation of the first product massecuite, in the second period the amounts removed were 32 and

38 per cent., and in the third period 40 and 41 per cent. The results also show that the work in the Dutch factories is, on the average, better conducted than that in the Belgian factories.—L. E.

Carbonation [Sugar manufacture]; Latest improvements in ——. Dutilloy. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 111—114.



The continuous carbonation process when properly conducted gives excellent results. The supply of juice and gas is regulated by frequent testing of samples taken from the carbonating apparatus. In practice the process is controlled by the adjustment of the rate of supply of juice, that of gas being seldom altered. The supply of juice must be regular, and the proportion of lime in the juice must be nearly constant. A proper degree of alkalinity of the carbonated juice is not a sufficient guarantee of satisfactory working, since this may be the result of a mixture of over-carbonated juice with juice containing too much alkali. The working of the process is simpler than that of the older methods, but it requires constant attention.

In factories where continuous control cannot be ensured, the author recommends the use of the ordinary cylindrical apparatus with a new form of gas distributor. This consists of a bell-shaped apparatus (see figure), the notched edge of which causes a more thorough agitation of the juice and perfect utilisation of the gas. Three of these distributors are employed in each carbonating vat. Two vats of 60 hectols. working capacity are sufficient to deal with the juice from 500 tons of beetroot.—L. E.

Sucrose; Polarimetric determination of —— II. F. Watts and H. A. Tempany. XXIII., page 957.

Sugars and glucosides; Benzal derivatives of ——. A. v. Eckenstein and J. Blanksma. Rec. trav. chim. Pays-Bas, 1906, **25**, 153; Chem.-Zeit., 1906, **30**, Rep., 301—302.

In the presence of phosphorus pentoxide, arabinose combines with benzaldehyde to form dibenzal-arabinose

a well crystallised substance (m.pt. 154° C.), which contains no hydroxyl groups. Xylose and rhamnose form similar compounds. Dilute sulphuric acid decomposes these benzal derivatives into the sugar and benzaldehyde. The hexoses also react with benzaldehyde in the presence of phosphorus pentoxide; the condensation products, however, could only be obtained in the form of syrups, and, unlike the benzal pentoses, they are capable of taking up an acetyl group. The glucosides combine with benzaldehyde much more readily than the sugars. By heating a glucoside with benzaldehyde and anhydrous sodium sulphate, a well crystallised body is obtained which does not reduce Fehling's solution, and which is decomposed by dilute sulphuric acid. From *α*- and *β*-methylglucoside monobenzal derivatives were obtained; *α*-methylmannoside yielded a mono- and a dibenzal-methylmannoside. Salicin and arbutin furnish monobenzal compounds. The aldehydes of tolulo and cuminic acids also give condensation products with pentoses and glucosides; salicylic aldehyde on the contrary does not react with the sugars.—L. E.

Vinasse; Influence of sulphur compounds on the refining of ——. Lecombe. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 46—51.

Owing to the employment of sulphites as clarifying agents for sugar juice, the vinasse obtained from juice so treated contains a considerable quantity of sulphides, sulphites, hyposulphites, and thiocyanates. The presence of these substances interferes with the accuracy of the titration of the potassium carbonate in the vinasse; the hyposulphites, in oxidising to sulphates on calcination, decompose some of the potassium carbonate. Moreover, to obtain a calcined product containing 75—80 per cent. of carbonate, the lye must be evaporated to a greater concentration when these substances are present, the consumption of fuel being thereby increased. The author considers that care should be taken that the secondary combustion which occurs through contact with the air, when the calcined vinasse leaves the furnace, is as complete as possible, so that the sulphur compounds are converted into sulphates. He also considers that in the analysis of the calcined vinasse the lower compounds of sulphur should be oxidised to a degree corresponding to the oxidation which occurs in the subsequent refining of the calcined vinasse, so that the value of the sample may be accurately judged.

In the discussion which followed, H. Pellet recommended the abandonment of sodium bisulphite as a clarifying agent.—L. E.

Waste waters [from manufacture of beet sugar]; Re-employment and purification of ——. *Application of carbonation.* H. Pellet. Bull. Assoc. Chim. Sucr. et Dist., 1906, **24**, 58—67.

The author recommends carbonation as a means of purifying the waste water from the beetroot presses and from the diffusion process. This method presents the following advantages: 1. Reliable purification and production of a clear water free from all noxious organisms. 2. Recovery of all the sugar present in the waste waters. 3. Recovery of a considerable proportion of water ready for direct use in diffusion. 4. Reduction of the number of vats required for decanting and purifying the waste waters. 5. Elimination of all the trouble caused by running the waste waters of the refinery into rivers. 6. Small initial expense of installation, which takes up less space and is always ready for use; the cost of working is covered by the value of the sugar obtained.

The author cites the results of a bacteriological analysis of the water before and after treatment by the carbonation process, which show that the process is very efficient, the purified water being comparable from a bacteriological standpoint to many potable waters. The purified water may readily be preserved without alteration, and as it would be used at once after purification in the diffusion battery, it should be preferable to ordinary water for this purpose, since the latter is sometimes contaminated with dissolved or suspended matters which are injurious to the regular working of the battery.

A sample of purified waste water from the press, after concentration, yielded a syrup having an apparent purity of 74·5. A blank experiment showed that 12·2 per cent. of impurity was due to mineral and organic matter present in the fresh diffusion water. Hence organic and mineral impurities from the beetroot are contained in the purified waste water in comparatively small quantity.—L. E.

Sugar production of Germany. Bd. of Trade J., Sept. 20, 1906. [T.R.]

THE "Reichsanzeiger" of September 14th publishes statistics of the production of sugar in Germany during the campaign 1905–06 (from September 1st, 1905 to August 31st, 1906). In 1905–06 the quantity of raw beet used in sugar manufacture was 15,728,425 metric tons as compared with 10,071,211 metric tons during the 1904–05 campaign; the amount of raw sugar produced in 1905–06 was 2,125,344 metric tons against 1,367,566 metric tons in 1904–05, whilst the production of refined sugar amounted to 1,709,099 metric tons in 1905–06, as compared with 1,286,328 metric tons in 1904–05. The total output of sugar (raw and refined) during the period of September, 1905 to August, 1906, expressed in terms of raw sugar, was 2,394,445 metric tons as compared with 1,605,438 metric tons in the corresponding months of 1904–5.

ENGLISH PATENTS.

Sugar masses; Apparatus for promoting the crystallisation of ——, and for intimately mixing other pulpy masses with diluting agents. T. Drost, Charlottenburg, Germany. Eng. Pat. 6009, March 12, 1906.

FOR promoting the crystallisation of sugar-masses by stirring, a special form of agitator is claimed, which is characterised by horizontal stirring arms to which a rocking motion is imparted in addition to the rotary motion of the stirring shaft. The rocking motion is obtained by means of spur wheels, r, r^1, r^2 (see figure), which cause the rotation of the crank shafts, s^1, s^2, constituting the top arms of the stirrer. These rotary crank shafts actuate the connecting rods, l, to which the other arms of the stirrer are linked, these other arms being connected to the central shaft by swivel joints, e. In this manner, all parts of the fluid are maintained in constant motion.—J. F. B.

Gum tragacol from locust-bean kernels; Manufacture of ——. P. C. D. Castle, Bebington, Cheshire. Eng. Pat. 10,822, May 24, 1905.

AN improved method of extracting gum tragacol from the locust bean (see Eng. Pats. 24,677 of 1894 and 6151 of 1899; this J., 1896, 112) consists in steeping 3 parts of prepared kernels in 10 parts of cold water containing about 1 per cent. of formalin for about one hour. The excess of water may then be drained off, and a further quantity of 10 parts of water with 1 per cent. of formalin added. After a short time, hot water is added at intervals of half an hour, until there are about 65—90 parts of water for every 3 parts of kernels, and the mash is maintained at a temperature of about 185° F. Finally, the solution of gum is strained through cloth. The formalin prevents the extraction of any of the colouring matter from the husks, which need not therefore be removed before treatment.—J. F. B.

UNITED STATES PATENT.

Saccharine liquids; Defecating ——. F. L. Stewart, Murrysville, Pa., Assignor to S. E. Gill, Pittsburg, Pa. U.S. Pat. 829,678, Aug. 28, 1906.

THE hot juice is neutralised, treated with a mixture of stearic acid and the sulphite of a light metal or of an alkaline-earth, *e.g.*, magnesium sulphite, the whole heated to boiling, and the clear juice separated from the precipitated impurities.—A. S.

FRENCH PATENTS.

Sugar from molasses; Process of extracting —— by the aid of a new compound. R. Battistoni and R. Rotelli. Fr. Pat. 364,639, Jan. 6, 1906. Under Int. Conv., Jan. 14, 1905.

THE molasses is diluted with water, and treated with a quantity of alkali carbonate solution in order to precipitate the calcium salts present. After filtration, the liquid is mixed with another liquid containing carbon and barium hydroxide, obtained by carbonising barium sucrate. The barium sucrate may be washed with a saturated barium hydroxide solution, or it may be decomposed by treatment with carbon dioxide, and then mixed with powdered charcoal before filtration. The mother-liquor from the barium sucrate precipitate can be treated with carbon dioxide, filtered, and the filtrate concentrated to form a manure after being mixed with calcium sulphate or peat. The mixture containing carbon and barium oxide used for precipitating the sugar is called "baryundum," and is prepared by heating the cakes of barium carbonate, obtained from the sugar solutions, in an electric furnace; native barium carbonate mixed with charcoal, sugar, and sodium and potassium salts may also be employed for preparing the compound. Whilst in the furnace, the charge is subjected to heating and electrolytic actions, and the process may be applied to the preparation of pure barium oxide or a mixture of the oxide and sulphide from barium sulphite or sulphate. Strontium oxide can be obtained in a similar manner. The carbon dioxide liberated from the barium carbonate in the furnace is collected and utilised for the carbonation of the sugar solutions.—W. P. S.

Starch; Process of preparing —— to render it capable of swelling in cold water. The Arabol Manufacturing Co Fr. Pat. 365,161, April 10, 1906.

SEE Eng. Pat. 7705 of 1905; this J., 1906, 601.—T. F. B.

Gum solutions; Preparation of aseptic ——. Zieger und Wiegand. Fr. Pat. 365,193, April 13, 1906.

SOLUTIONS of gum may be rendered aseptic, for surgical use, by treating them with formaldehyde. The latter is added in the form of an ethereal solution, the ether serving as a carrier for the formaldehyde, and preventing the precipitation of the gum by the latter.—W. P. S.

GERMAN PATENT.

Animal or bone charcoal; Process for the preparation of purified ——, by means of an acid. G. Banfi. Ger. Pat. 168,034, Dec. 1, 1904.

ANIMAL charcoal is treated, in presence of water, with

sulphur dioxide gas under slight pressure, in order to convert the calcium carbonate and calcium phosphate contained in it into soluble calcium salts, which can be removed by washing first with dilute sulphurous acid solution, and afterwards with water.—A. S.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 903.)

Diastase; Preparation of pure ——, and its properties. S. Fränkel and M. Hamburg. Woch. f. Brau., 1906, 23, 473—475.

Five kilos. of malt grist, prepared from highly diastatic malt, are mashed with 15 litres of water at 25° C. After stirring for one hour, the mash is allowed to stand for half an hour. The diastatic power (liquefying and saccharifying power) of a measured quantity of the aqueous extract is then determined To an equal quantity of the extract, measured amounts of basic lead acetate solution are added so long as the diastatic power shows no sensible change. The bulk of the extract is now treated with the calculated amount of the lead solution, the avoidance of excess of the latter being assured by testing a small portion of the filtrate with ammonium sulphide. The lead precipitate is allowed to settle, the solution filtered through paper, and then rapidly through a sterilised Pukal filter into a sterile flask. After seeding with a small quantity of a pure culture of Frohberg yeast (previously cultivated in a nutrient medium poor in sugar and rich in diastase), the solution is fermented in a thermostat at 28° C. When fermentation is finished, the solution is again passed through a Pukal filter, into a previously sterilised vacuum apparatus, and evaporated at 10 mm. pressure to a volume of about 500 c.c. If the solution has become acid it must be neutralised with sterilised calcium carbonate. The solution is now sown with a very small quantity of a mixed culture of Frohberg and Logos yeasts (previously cultivated as above). In this second fermentation, which should be carried as far as possible, the yeast employed should be cultivated so as to be capable of assimilating nitrogen very readily. After filtration through a Pukal filter again, the solution is concentrated *in vacuo*, and, under favourable conditions, a syrupy liquid is obtained, which by further concentration in an absolute vacuum, over sulphuric acid, can be converted into a powder. A substance is thus obtained which is free from fermentable and reducing carbohydrates, and which gives no reaction for albumin. The diastase prepared by the authors is much more sensitive to the action of chemicals (alcohol, ether, acetone) than ordinary impure diastase. It is a light yellow powder, easily soluble in water, insoluble in alcohol; it does not give the biuret reaction, nor does it reduce Fehling's solution. It reacts with Millon's reagent slightly. The aqueous solution may be partially salted out with sodium chloride, ammonium sulphate, or magnesium sulphate.

The authors have investigated the problem of precipitating diastase from pure aqueous solutions. Colloidal ferric hydroxide appears to be the only substance of those investigated capable of effecting this practically completely, but by this process it is quite possible that the diastase is destroyed, as the precipitate has practically no diastatic power. The incapacity of colloids and of electrically charged colloids to precipitate diastase from its solution argues against the colloidal nature of the latter. An electric current passed through a diastase solution does not cause the diastase to travel towards either anode or cathode. When the diastase solution is examined with an ultramicroscope, bi-concave pencils of light are observable, indicating the presence of very minute particles, whence it would seem that diastase is of a colloidal nature. By dialysing diastase solution against boiled spring water the authors have succeeded in separating to a certain extent the two chief groups of diastases (saccharifying and liquefying diastases) which constitute ordinary diastase.—L. E.

Ferments and life of micro-organisms; Action of compressed gases on ——. C. Fok. Atti R. Accad. dei Lincei Roma, 1906, 15 [II.], 53—58; Woch. f. Brau., 1906, 23, 476.

The author has studied the action of oxygen, hydrogen, and carbon dioxide at pressures of two, three, four, and five atmospheres on *Bacillus subtilis*, *Sacch. inversus*, *Sarcina aurantiaca*, *Bacillus typhi*, and *Sacch. cerevisiæ*. Hydrogen, at four atmospheres, in the presence of oxygen at normal partial pressure showed no injurious action on the micro-organisms, nor on the activity of ferments; oxygen and carbon dioxide, on the contrary, showed an inhibiting effect on the development of the organisms, but did not affect enzymes injuriously. Unlike oxygen, carbon dioxide at four atmospheres retarded alcoholic fermentation.—L. E.

Enzymes (Invertase); Action of light on —— in absence of oxygen. A. Jodlbauer and H v. Tappeiner. Münchener Med. Woch., 1906, 653; Woch. f. Brau., 1906, 23, 476.

The authors have previously shown that light free from ultra-violet rays exerts an injurious action on enzymes. They have now extended their investigations to the action of light as a whole. The enzyme, placed in an illuminated flask, was affected injuriously even when the flask was filled with hydrogen, nitrogen, or carbon dioxide, *i.e.*, in the absence of oxygen.—L. E.

Wort cooling; Inexpensive ——. T. Pongratz. Woch. f. Brau., 1906, 23, 468—470.

The author recommends the employment of a cooling vat placed between the cold water cistern and the liquor back as a substitute for the ordinary wort cooler. The wort from the hop filter is sprayed into the cooling vat, coming in contact at the same time with a current of cold air. The cooling vat contains a system of tubes through which passes a stream of cold water from the cold water cistern to the liquor back. A continuous stream of cold sterile air is passed over the surface of the wort when all the latter has been pumped into the vat, in order to produce further evaporation and absorption of oxygen; at the same time albuminoid matter settles to the bottom of the vat. According to results of experiments, temperatures below 50° C. have no influence on the colour or degree of attenuation of the wort, and this temperature is attained as quickly by the above method as by the ordinary cooling process. In breweries where an abundant supply of water is not available, a portion of the water which has circulated through the cooling vat may be passed into a special cistern, whence it may be pumped back into the cold water cistern on the following day to be used again for cooling purposes.—L. E.

Musts and wines; Speed of inversion of sucrose in ——. L. Mathieu. Bull. Assoc. Chim. Sucr. et Dist., 1906, 24, 79—82.

The author has investigated the speed of inversion of sugar added to actively fermenting wine or must, to wine undergoing secondary fermentation, and to completely fermented wine. With wine undergoing active fermentation, the sucrose had disappeared in all cases within 24 hours. Hence if sucrose be added at the beginning of fermentation or during active fermentation, it is quite unnecessary to invert it beforehand, since the acidity of the wine and the invertase secreted by the yeast effect inversion rapidly. In the case of wine undergoing secondary fermentation, the inversion is slower but complete; hence the utility of preliminary inversion of the sucrose added is doubtful. In the case of completely fermented wines, inversion proceeds still more slowly the rate of inversion decreasing as the percentage of alcohol increases; in a sample of red wine containing 16·4 per cent. of alcohol, all the added sucrose was inverted after three months. To retard or arrest the hydrolysing action of must or wine, it is sufficient to add an excess of at least 4 grms. per litre of crystallised sodium carbonate. —L. E.

Wine; Ageing of ——. M. Schtscherbakow. Winogradstwo i Winodjelie, July 22, 1906. Chem. Centr., 1906, 2, 623—625.

The author has studied the formation and decomposition of volatile and non-volatile esters and volatile acids, and the alteration of the amount of total acid during fermentation. If the quantities of alcohol formed during the fermentation of wine-must be plotted as ordinates, and the time as abscissæ, the curve rises at first (20 days), and after attaining a maximum becomes, roughly, a horizontal line; there are, however, irregularities in the curve, indicating periods in which a diminution of the amount of alcohol produced occurs. The curve representing the amount of volatile acids is similar, in its first portion, to the alcohol curve, but after attaining a maximum it descends, the amount of acids formed showing a decrease. There are many more irregularities in the curve corresponding to the volatile acids than in the alcohol curve. After fermentation is complete, the amount of volatile acids becomes less, probably owing to decomposition by certain enzymes, and also to the acids being utilised as food by the yeast. The quantity of volatile acids formed by the auto-fermentation of yeast is extremely small under ordinary conditions. The volatile acids are exposed to continual processes of formation and of decomposition. After fermentation is complete, the quantity falls gradually to a minimum, and then in the course of two to three years again increases to twice or three times the minimum quantity, owing to the action of atmospheric oxygen. Esters are formed chiefly during the period of energetic fermentation, and only in smaller quantities afterwards. The curves representing the formation of volatile and non-volatile esters respectively, show great similarity, but the volatile esters are produced in smaller quantities than the non-volatile. In both cases, after the maximum is passed, the curves show breaks and irregularities, indicating continual formation and decomposition of the compounds, these changes being probably caused by enzymes secreted by the yeast. The formation of esters during the fermentation period is not to be attributed to the interaction of alcohol and acids, but is a result of the vital activity of the yeast organisms. Moreover, the esters are only intermediate products in the formation of other compounds, the nature of which has not yet been determined. When wine is kept under ordinary conditions, the quantity of non-volatile esters gradually diminishes, and the development of bouquet must therefore be due to other factors. The quantity of volatile esters increases with the age of the wine. The total esters decrease in quantity as the age of the wine increases, the diminution being greater the more the bouquet and flavour of the wine are developed. The acidity of wine varies to a considerable extent during the fermentation period; the largest amount of acid is formed concurrently with the production of the largest quantity of alcohol. This relation between the formation of acids and of alcohol can be easily explained in the light of the results obtained by Buchner and Meisenheimer (this J., 1905, 246). On keeping wines under normal conditions, the quantity of free acid first shows a distinct diminution, then increases, and subsequently remains fairly constant. The flavour of the wine, however, becomes more pleasant and less sour, probably owing to a change in the nature of the acids. The quantity of lactic acid varies considerably, according to the kind of yeast used; in general it increases with the age of the wine.—A. S.

Wines; Persian ——. O. Lecomte. J. Pharm. Chim., 1906, 24, 246—247.

In the following table the results of the analysis of seven wines from the districts of Cazevine and Schariare, Persia, are given:—

Geographical source of wine.	Red wines.					White wines.

Rum; Manufacture of Jamaica ——. C. Allan. West Ind. Bull., 1906, 7, 141—145.

Two types of rum are produced in Jamaica, known respectively by the names of "common clean" and "flavoured" or "German" rum. The flavoured rum is only manufactured on certain estates and in certain districts, and somewhat complicated processes are adopted. The enhanced value of the highly flavoured rums is directly attributable to their high contents in compound ethers. From a large number of analytical results, the author concludes that whenever a rum contains over 1,000 parts of esters per 100,000 of alcohol, that rum invariably commands a high price. In the manufacture of flavoured rum the wash is set up with "skimmings," "dunder" (vinasse), molasses, "acid," and "flavour."

"Acid" is made by fermenting "rum cane juice" which has been warmed in the coppers. To this juice "dunder" is added, and sometimes a little "skimmings." When fermentation is nearly over, the fermented liquor is pumped on to "cane trash," and allowed to get sour; the ripe "acid" has an odour like sour beer. Sludge settled out from fermented wash is added from time to time. "Flavour" is prepared by running fermented cane juice into cisterns outside the fermentation house along with cane trash and "dunder" which has been stored from the previous crop. The fermentation of the "flavour" in presence of cane trash with the addition of "dunder" is effected three times before the "flavour" is ready. "Skimmings" are run from the boiling house into cisterns half-full of cane trash, and are allowed to ripen for four to six days before they are used for setting up the wash. Fermentation lasts for seven to eight days, but a period of 13 to 14 days elapses between the setting up of the wash and the distillation.—J. F. B.

Beetroot vinasse; Concentration of ——, *with regard to the production of manure.* P. Kestner. Bull. Assoc. Chim. Sucr. et Dist., 1906, 24, 86—90.

For the recovery of saline matter from vinasse it is sufficient to concentrate the latter to about 40° B. before

incineration. In order to recover the nitrogenous matter as well, the concentration of the vinasse must be carried to 40° B., the resulting syrup being mixed with peat, and used as a manure. The author has made an estimate of the cost of the latter process in the case of a sample of diffusion vinasse. He considers that the margin of profit is sufficient to justify experiments on a commercial scale. —L. E.

Alcohol used under the Act of 1902. Pharm. J., Sept. 22, 1906. [T.R.]

THE report of the Commissioners of Inland Revenue, just issued, states that during the year ended March 31, 1906, 354,516 proof gallons of spirit were used in connection with arts and manufactures under the Finance Act, 1902. The following table shows the quantities used under the 1902 Act since its provisions came into force:—

Year ended March 31.	Use.	Total.
		Proof galls.
1902–03	Arts and manufactures ..	341
	Scientific (universities, hospitals, &c.)	358
		699
1903–04	Arts and manufactures ..	206,452
	Scientific (universities, hospitals, &c.)	2,272
		208,724
1904–05	Arts and manufactures ..	267,706
	Scientific (universities, hospitals, &c.)	2,680
		270,386
1905–06	Arts and manufactures ..	354,516
	Scientific (universities, hospitals, &c.)	3,314
		357,830

ENGLISH PATENTS.

Grain; Preparation of —— for brewing and the like. K. J. Somló, Temesvár, Hungary. Eng. Pat. 367, Jan. 5, 1906.

SEE Addition of Jan. 12, 1906, to Fr. Pat. 331,578 of 1903; this J., 1906, 773.—T. F. B.

Beer; Improving the flavour and aroma of carbonic acid gas used for carbonating ——. A. Hartley, Emsworth, Hants. Eng. Pat. 2559, Feb. 2, 1906.

THE carbon dioxide gas intended for carbonating beer is passed through a cushion or mass of hops at a temperature between 60° and 120° F. The hops are placed in a vertically disposed vessel consisting of a tube or cylinder, surrounded by a heating jacket, the arrangement being carried by a suitable frame-work. Caps are fitted to the ends of the containing tube or cylinder, one cap being connected with an inlet nozzle and the other with an outlet nozzle for the gas.—J. F. B.

UNITED STATES PATENTS.

Ferment and process of producing the same. G. Johnson and P. R. Hare, Bromley. U.S. Pat. 830,506, Sept. 11, 1906.

SEE Eng. Pat. 10,093 of 1903; this J., 1904, 499.—T. F. B.

Wort; Process of treating and ageing ——. H. E. Deckebach, Cincinnati, Ohio. U.S. Pat. 803,576, Sept. 11, 1906.

WORT is fermented in two stages in the following manner: The wort is placed in contact with the yeast, and fermentation is allowed to proceed for only a short time; it is then checked by chilling the partially fermented wort, and the main portion of the yeast is separated at a low temperature. The wort still containing yeast in a finely divided and suspended condition is then placed in a closed vessel at a higher temperature, and fermentation is allowed to complete itself under pressure so as to develop the necessary quantity of gas.—J. F. B.

FRENCH PATENTS.

Wines; Process for improving —— before fermentation. E. A. Barbet. Fr. Pat. 361,483, May 18, 1905.

THE grape juice issuing from the press is subjected to (preferably continuous) distillation in a column still, under reduced pressure and with partial aëration, by means of low-pressure steam circulating through tubes, a coil, or a steam jacket. This treatment removes any unpleasant odours, and concentrates the juice so that it will furnish wines containing "11°—12°" of alcohol without fortifying. —C. S.

Liquids such as fruit juices, fermented liquors, &c.; Process and apparatus for sterilising ——. P. M. C. Mauvernay. Fr. Pat. 365,425, April 19, 1906. XVIII*A*., page 949.

Worts, juices, and syrups; Process for preparing concentrated —— [*retaining their natural aroma*]. E. Monti. Fr. Pat. 365,338, April 17, 1906.

THE fruit, such as grapes, lemons, &c., is cooled to a temperature of 0° C., as soon as possible after being gathered. The juice is then expressed at the same temperature, and concentrated by freezing, the ice being removed. After filtration, the concentrated juice may be pasteurised under pressure in an atmosphere of carbon dioxide. Cream of tartar may be separated from the residue obtained on the filter.—W. P. S.

Alcohol and the like; Rectification of ——. E. Guillaume. Fr. Pat. 365,417, April 19, 1906.

A SPECIAL column is placed between the rectifying column and the final purifying column in order to combine the process of "final purification" with that of "pasteurisation." A device for regulating the discharge of the vapours from the head of the rectifying column is also employed. This device consists of a side tube fitted on the tube leading to the cooling chamber and outlet, and serves the purpose of supplying the outlet with spirit from a separate condenser, or of taking up any surplus of condensed liquid.—W. P. S.

Distillation residues of starchy matters [*Vinasse*]; *Process for recovering* ——. F. and E. D. Verbiese. Fr. Pat. 361,534, June 2, 1905.

THE vinasse is treated with quicklime, slaked lime, milk of lime, or lime water, the resulting precipitate being recovered in a filter-press, and utilised as a manure, since it contains part of the nitrogenous matter and nearly all of the phosphoric acid of the vinasse. The filtrate, which now has a constant alkaline reaction, is passed through a multiple evaporator of any suitable type, and the resulting syrup, after being concentrated if necessary, is mixed with oil cake, chaff, or other solid matters for use as fodder.—C. S.

Amylaceous matters; Recovery of the residues from the distillation of ——. F. Verbiese and E. D. Verbiese. First Addition, dated June 5, 1905, to Fr. Pat. 361,534, June 2, 1905 (see preceding abstract).

ANY of the alkalis or alkali carbonates may be used in place of calcium carbonate to neutralise the acidity of the vinasse before evaporation.—W. P. S.

Tartaric acid and tartrates from grape residues and the like; Extraction of ——. P. P. Carles. Fr. Pat. 365,084, April 9, 1906. XX., page 952.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 905.)

(*A.*)—FOODS.

Seaweed industry of Japan. C. J. Davidson. Bull. Imp. Inst., 1906, **4**, 125—149.

In Japan, seaweeds are utilised as foodstuffs, in the preparation of plaster, glue, and isinglass, as manure for rice fields, and for the extraction of iodine. The present article deals with the preparation of *kanten* (isinglass), *kombu* (kelp), *amanori* (laver), and *funori* (seaweed glue), and the extraction of iodine. It should be noted that in Japan the word "nori" is frequently used to designate useful seaweeds generally, but properly speaking it should only be applied to laver. There is another word "nori," meaning paste or mucilage, which is used in the names of those species of "*funori*" (*Gloiopeltis sp.*) from which paste or mucilage is prepared, and care must be taken to distinguish between the two.

Kanten, or seaweed isinglass, is prepared chiefly from seaweeds of the species *Gelidium*, especially *G. sawanii* Japanese: *tengusa*), but such seaweeds as *ego* (*Campylaephora hypneoides*), *tori-ashi* (*Acanthopeltis japonica*), and *ogo* (*Gracilaria confervoides*) are also frequently employed as substitutes, or are added to the *tengusa* in larger or smaller quantities according to the quality of *kanten* to be made; the best quality of *kanten* is, however, made from *tengusa* alone. The seaweed, dried and partially bleached by exposure on the sea-shore, is freed from mechanical impurities by pounding in a mortar, and washing with water, and is then completely bleached by exposure. It is next boiled with water (about 950—1000 galls. per 165 lb. of seaweed) for 5—6 hours, with occasional agitation, 1½ galls. of vinegar or 2 oz. of sulphuric acid added, and then 30 galls. of water, and the whole boiled for a further 30 minutes. The resulting gelatinous solution is strained twice through coarse cloths, and then allowed to set, the jelly being called "*tokoro-ten.*" The jelly is congealed by exposing it at night during very cold weather, and is finally dried by exposure to the rays of the sun. Ordinary *kanten* or "*kaku-kanten*" is made in the shape of bars, 17 in. by 1·4 in. by 1·6 in.; "*hoso-kanten*" is made in the form of slender sticks, 10—14 ins. long and ½ in. thick. The preparation of *kanten* of good quality by the process described is stated to depend almost entirely upon the atmospheric conditions, especially during the bleaching and congealing operations. *Kanten* is used for the preparation of edible jellies, for clarifying wines and *saké*, as a sizing material for textiles and paper, and as a cultivating medium for bacteria. A specimen gave the following results on analysis:—Water, 21·79; nitrogenous organic matter, 5·95; carbohydrates, 64·59; cellulose, 3·54; and ash, 4·13 per cent. In the following table, the amount and value of the *kanten* produced in and exported from Japan during recent years is given:—

Year.	Production.		Exports.	
	Amount in kwan.	Value. £	Amount in kin.	Value. £
1900....	284,462	115,300	1,444,499	96,432
1901....	261,344	106,846	1,584,748	121,719
1902....	271,436	95,027	1,665,501	110,854
1903....	266,914	90,997	1,391,268	81,817
1904....	—	—	1,776,098	101,359

1 kwan = 8·2673 lb. 1 kin = 1·32277 lb.

The greater bulk of the *kanten* exported goes to China and Hong Kong. *Kombu* or *kobu* belongs to the family of "kelps" (*Laminariacæ*), and is the most prolific seaweed found on the coast of Japan. *Kizami-* (sliced) *kombu* is prepared by boiling the kelp with water, drying, and shredding the dry material. Preparations are also made from *oni-kombu* (*Laminaria diabolica*) by soaking in vinegar, drying, and scraping the dry substance, and from other kinds of kelp. Kombu is used in a variety of ways for culinary purposes. An analysis of *Laminaria longissima* by K. Oshima gave the following results:—Water, 25·944; proteids, 6·724; fat, 1·730; soluble non-nitrogenous matter, 31·896; fibre, 6·415; and ash, 27·290 per cent. The production and exports of *kombu* during the five years ending 1904 were as follows:—

Year.	Production of Kombu.		Exports.			
			Kombu.		Kizami-kombu.	
	Amount in kwan.	Value. £	Amount in kin.	Value. £	Amount in kin.	Value. £
1900	6,454 078	60,277	30,988,010	73,084	5,053,001	15,288
1901	9,216,765	92,816	51,526,468	109,292	9,383,262	32,540
1902	5,073,689	36,904	33,021,851	60,914	6,346,523	20 034
1903	7,099,598	60,698	43,699,026	83,929	6,808,784	20,430
1904	5,043,200	49,691	45,158,836	105,415	5,847,738	19,235

Asakusa-nori, or laver, is the only seaweed which is regularly cultivated in Japan. The method of cultivation of laver (*Porphyra tenella*; Japanese: *Asakusa-nori*, *nori*, or *amanori*) consists in planting, at about the middle of September, branches of trees in rows from 30—70 yards long, and about 8 ft. apart, the branches being inclined at an angle of about 45° towards the flowing tide, and rising 6—9 ft. above the mud. The floating spores of the *Porphyra* attach themselves to the branches. The laver is gathered from January to near the end of March. It is freed from mechanical impurities, washed in salt water, chopped up finely, and thrown into fresh water (12 galls. to 8 bushels of laver). A small quantity of rape oil is added to destroy the froth which rises to the surface of the water, the laver is removed, drained on mats, and dried in sunlight. A specimen gave the following results on analysis:—Water, 15·475; proteids, 34·350; fat, 0·650; and ash, 10·685 per cent. The production of *nori* during the four years ending 1903 was as follows:—

Year.	Amount in kwan.	Value.
1900.....	154,853 ..	£51,394
1901.....	433,501 ..	77,420
1902.....	249,525 ..	71,158
1903.....	335,940 ..	89,526

The exports of *nori* are increasing yearly, and exceed 10,000 yen in value.

Funori, or seaweed glue.—The name, *funori*, is applied to seaweeds from which mucilage can be made, and also to the mucilage itself, but the word is written with different Chinese characters in the two cases. The

seaweeds chiefly used in Japan for the preparation of mucilage are the various kinds of *funori* (*Gloiopeltis coliformis* and other species) and *tsunomata* (*Chondrus sp.*). If the seaweed be of a tough character, it is subjected to a preliminary treatment consisting of soaking in water, steaming, cutting into small pieces and drying, but slender and soft seaweeds are used as collected. The material is spread on the ground, sprinkled with water, kneaded with the hands and feet, washed with water, and dried and bleached by exposure, with occasional sprinkling with water. When a sticky juice is observed to exude from the material, no more water is used, but the seaweed is left for one night, after which it is ready for sale. It is made into glue or paste by dissolving in boiling water, and is used as a finish for textiles, for plastering walls, and for decorating chinaware. Other kinds of seaweed used for making mucilage, besides those already mentioned, are:—*Ginnanso* (*Iridæa sp.*), *mukade-nori* (*Grateloupia ficilinus*), *kotoji-tsunomata* (*Chondrus etatus*), *tamba-nori* (*Grateloupia sp.*), *tobera* (*Chondrus sp.*), *saimi* (*Gymnogongrus sp.*), and *yanagi-funori* (*Gloiopeltis tenax*). The production of *funori* during the four years ending 1903 was as follows:—

Year.	Amount in kwan.	Value.
1900.....	257,932 ..	£15,406
1901.....	355,481 ..	26,161
1902.....	284,083 ..	26,794
1903.....	181,513 ..	16,660

Extraction of iodine.—The seaweeds chiefly used in Japan for the extraction of iodine are:—*Kombu* (*Laminaria sp.*), *kajime* (*Ecklonia cava*), *arame* (*Ecklonia bicyclis*), *hondawara* (*Sargassum horneri*), and *yatsumata-moku* (*Sargassum patens*). Analyses of specimens of different kinds of seaweed gave the following results:—Waste *kombu*, 0·144; *kajime* stems, 0·148; *kajime* fronds, 0·002; *arama*, 0·0003; and *nagahijiki* (*Cystophyllum*), 0·005 per cent. of iodine. The iodine content varies, however, with the age of the algæ, and also with the time of year, being greatest during June to September. The iodine is extracted by charring or burning the seaweeds, leaching the ash with water, evaporating the solution, and heating the residue with sulphuric acid and manganese dioxide. The amount of potassium iodide exported during the three years ending 1904 was as follows:—

Year.	Amount in kin.	Value.
1902.....	3,051 ..	£1,482
1903.....	22,371 ..	10,117
1904.....	52,012 ..	26,680

It is stated that investigations are being carried out under Government supervision as to the cultivation and collection of useful kinds of algæ, and the most economical and productive method for the extraction of iodine.

The total value of the seaweeds prepared in Japan in 1904 exceeded £400,000, and the total value of the exports was £124,651. The value of the exports of seaweeds from Japan to various countries during the five years ending 1904 was as follows:—

	1900.	1901.	1902.	1903.	1904.

English Patents.

Chocolate; Process for the manufacture of malt-containing ——. J. Meinl, Vienna. Eng. Pat. 24,414, Nov. 25, 1905.

See Addition of Dec. 9, 1905, to Fr. Pat. 316,861 of 1901; this J., 1906, 651.—T. F. B.

Homogenising breaker to emulsionise, pulverise, and homogenise liquid and semi-liquid matters [*milk*], *and break fatty or albuminous cellules and nuclei.* C. Petitpierre, Paris. Eng. Pat. 10,162, May 1, 1906.

See Fr. Pat. 353,753 of 1905; this J., 1905, 1055.—T. F. B.

French Patents.

Distillation residues of starchy matters [*Vinasse*]; *Process for recovering* ——. F. and E. D. Verbièse. Fr. Pat. 361,534, June 2, 1905. XVII., page 947.

Desiccation; Process of ——, *applicable especially to vegetable substances.* P. Rasmus. Fr. Pat. 365,051, April 10, 1906. Under Int. Conv., March 17, 1906.

The process claimed consists in exposing the materials to be dried alternately to heat alone and to heat while a current of air is passed over them.—W. H. C.

Alimentary materials; Process for treating [*rendering more digestible*] ——. E. Maris. Fr. Pat. 365,069, April 10, 1906.

The process consists in treating all kinds of food materials and fodders with specific ferments and yeasts, the operations being carried out in closed vessels at various temperatures and for different periods of time. The treatment increases the digestibility of the foods.—W. P. S.

Liquids such as fruit juices, fermented liquors, &c.; Process and apparatus for sterilising ——. P. M. C. Mauvernay. Fr. Pat. 365,425, April 19, 1906.

The liquid to be sterilised is heated in a serpentine tube surrounded by a steam-jacket. During the heating process the liquid is subjected to a pressure equal to at least three times the vapour pressure of the volatile constituents present in the liquid. To aid in the thorough heating of every part of the liquid during its passage through the steriliser, boxes or enlargements are placed on the serpentine tube at regular intervals. The pressure is kept constant automatically, and the sterilised liquid is cooled by passing it through a coil surrounded by liquid on its way to the steriliser, the pressure being maintained during the cooling operation.—W. P. S.

(*B.*)—SANITATION; WATER PURIFICATION.

United States Patents.

Garbage and sewage; Process of reducing ——. E. R. Edson, Cleveland, Ohio. U.S. Pat. 829,954, Sept. 4, 1906.

The garbage or sewage is digested in a closed chamber at a temperature above 285° F., and under a pressure of from 75 to 80 lb. per sq. in., for a period long enough to thoroughly disintegrate the mass, and to render the grease easily separable by percolation. The liberation of ammonia and the volatilisation of glycerol during this digestion are prevented by the high pressure used. The digested material is then dried so as to remove substantially the whole of the water, and the dried mass is extracted with a solvent.—A. G. L.

Garbage and sewage; Apparatus for reducing ——. E. R. Edson, Cleveland, Ohio. U.S. Pat. [illegible] Sept. 4, 1906.

The apparatus claimed is used in carrying out the process described in the preceding abstract. It comprises [illegible] upright shell forming a jacket and provided with a [illegible] for this shell. A receptacle for receiving the [illegible] to be treated is suspended from the upper end of the [illegible]

receptacle, and is provided at its upper end and externally with a flange resting upon and removably secured to the shell. The head forming the top wall of the chamber of the receptacle is provided with a charging aperture, and rests upon, and is removably secured to, the cast-iron section of the receptacle.—A. G. L.

[*Water*] *Distilling apparatus.* W. H. Bartholomew, East Orange, N.J., Assignor to C. B. Hill, Montgomery, N.Y. U.S. Pat. 829,756, Aug. 28, 1906.

A WATER distilling apparatus is claimed, comprising a still which is connected with a condenser, surrounded by a jacket, and with a receptacle consisting of a pair of telescopic members. A feed-pipe connects the still with the lower of these members, terminating some distance above the bottom of the receptacle, the space below forming a chamber for the accumulation of sediments which may be removed by a discharge pipe. The upper member is adjustably supported by the lower one. The condenser jacket is provided with an inlet for the water supply, and an overflow at its upper end leading to a point within the receptacle. An overflow at the upper part of the receptacle allows impurities to run off. The still communicates with the condenser through a coil in the receptacle, and the condenser is provided with an outlet near its bottom.—R. L.

Water; Apparatus for distilling ——. C. Parker, Dubuque, Iowa. U.S. Pat. 829,999, Sept. 4, 1906.

THE still comprises a boiler, a diaphragm arranged in the path of the steam-current and constructed with openings so as to direct the steam at right angles to its normal path, a condensing chamber, a reservoir placed between the condensing chamber and diaphragm, and means of communication between the spaces above the diaphragm and the condensing chamber. The reservoir is provided with a normally sealed inlet tube, and a separating-chamber is arranged between the diaphragm and reservoir. —A. G. L.

XIX.—PAPER, PASTEBOARD, &c.

(*Continued from page* 906.)

Paper and solid cellulose [*and acetylcellulose*]; *Electrical insulating properties of dry* ——. A. Campbell. XI*A*., page 935.

Cellulose industry of Norway. Bd. of Trade J., Sept. 20, 1906. [T.R.]

THE Canadian Commercial Agent at Christiania reports that the cellulose mills now building in Norway and the enlargement of existing mills will cause an increase in the Norwegian output of cellulose of about 50,000 tons per year. The manufacturers reckon on a total increase of production in Norway and Sweden of about 130,000 tons in the two years 1907 and 1908.

The Norwegian and Swedish cellulose production has grown in the last seven years (including 1905) by some 240,000 tons, *i.e.*, from about 150,000 tons in 1898 to 394,000 tons in 1905.

ENGLISH PATENTS.

Paper pulp [*Draining*]; *Treatment of* ——. L. Evans, Watford. Eng. Pat. 19,808, Sept. 30, 1905.

IN the use of the "tower" system of treating and bleaching paper pulp, an improved form of drainer is claimed for the purpose of washing or draining the pulp in the tower. This drainer consists of one or more vertical frames or boxes rising from the base of the tower, and covered with wire gauze. In this arrangement, both sides of the drainer box are available for use, so that a maximum draining surface is obtained as compared with the displacement caused by the drainer.—J. F. B.

Cellulose; Manufacture of non-inflammable material containing non-nitrated ——. C. Trocquenet, Colombes, France. Eng. Pat. 8167, April 4, 1906.

SEE Fr. Pat. 362,989 of 1906; this J., 1906, 825.—T. F. B.

Cellulose; Manufacture of solutions of ——. E. W. Friedrich, Blaton, Belgium. Eng. Pat. 17,164, Aug. 24, 1905. Under Int. Conv., Aug. 25, 1904.

SEE Fr. Pat. 357,171 of 1905; this J., 1906, 88.—T. F. B.

UNITED STATES PATENT.

Paper pulp; Process of making —— [*from the Southern Pine*]. J. L. Coker, jun., Hartsville, S.C. U.S. Pat. 830,570, Sept. 11, 1906.

PAPER pulp is made from the wood of the Southern Pine by subjecting it, with its bark still on, to the action of "natural agencies," until tests show that the resinous constituents have become so modified that they no longer produce any injurious influence in the process of pulp-making. The bark is then removed, the trunk is split up into suitable lengths, the core or heart-wood is separated from the sap-wood, and the latter is converted into pulp by any suitable process.—J. F. B.

FRENCH PATENTS.

Paper-making; Utilisation of machine "back-waters" in ——. C. Gérard. Fr. Pat. 364,720, March 29, 1906.

ALL the "back-waters" from the paper-machine, together with the fibrous waste scraped off the top press-roll, are collected in a pit below the machine, and are pumped into a special reservoir at the top of the mill. This reservoir consists of two deep conical tanks, one relatively small, into which the pump discharges directly, and the other very large, which is fed by an overflow from the small one. The two conical tanks and the pump catch-pit can all be discharged into a "save-all" if necessary. In normal working, however, the "back-waters" are continuously re-utilised in the beating engines and stuff-chests. The discharge pipes from the large tank are situated at the apex of the cone, and are covered by a conical hood, which diverts the discharge stream in such a manner that any deposits of solid matters are washed through.—J. F. B.

Paper pulp from flax, hemp, ramie, &c.; Preparation of ——. Soc. anon. pour la Fab. des Pâtes à Papier de lin et succédanés. Fr. Pat. 365,046, April 9, 1906. Under Int. Conv., Oct. 6, 1905.

FLAX-STRAW, and similar materials consisting of bast (pectocellulose) and wood (lignocellulose) are treated in such a manner that the two components are separated, the bast fibres being purified, and the wood being obtained in the state of short fibres suitable for making millboards or paper. The stems are first passed through a breaker, then moistened, and subjected to a retting treatment, or else they are steamed in presence of air, caustic soda, &c. The mixture of fibres and wood so obtained is then exposed to the action of an oxidising agent such as chlorine gas or calcium hypochlorite in presence of steam, so as to disintegrate the wood without attacking the bast fibres. Finally, the material is boiled at a temperature of 150° C. in an alkaline liquid containing caustic soda and sodium carbonate, sulphate, and sulphite. The short wood fibres are then separated from the long bast fibres by washing on suitable sieves.—J. F. B.

Glue or size, and process of making the same. M. Bonnet. Fr. Pat. 365,285, April 14, 1906. XIV., page 942.

Cork; Artificial —— [*from cellulose*]. G. C. de Briailles. Fr. Pat. 364,641, Jan. 25, 1906.

ARTIFICIAL cork is made of a mixture of amorphous cellulose (pith of rushes, powdered cocoanut shells, bark, or paper pulp), fibrous cellulose (thistle-down, cotton, textiles, esparto, wood pulp), and agglutinating cellulose (solution of nitrocellulose). The pasty composition is pressed into glass-lined moulds provided with very small perforations for the escape of the vapours. The volatile solvents of the nitrocellulose are then distilled off under vacuum at the ordinary temperature, the corks are removed from the moulds, and the nitrocellulose is denitrated by a suitable reducing agent. Finally the corks

are dipped in an alkaline solution of tungstic acid, which imparts "water-resisting" qualities to the product. —J. F. B.

Celluloid; Plastic, non-inflammable composition resembling ——. A. Blanchin. Fr. Pat. 364,690, March 28, 1906.

Ten kilos. of nitrocellulose are dissolved in ether-alcohol, wood spirit, or acetone, and to the solution are added 0·5—1·2 kilos. of castor oil, glycerol, or camphor, 0·3—1·0 kilo. of sulphuric acid at 66° B., 1·0—2·5 kilos. of calcium chloride, and 0·5—1·5 kilos. of manganese chloride. In order to impart a certain amount of brilliancy to the product, 10—500 grms. of a chloride of carbon may be added. The mixture is thoroughly incorporated, and the volatile solvents are distilled off under vacuum until the product has a thick pasty consistence. The mass is then treated on the rolling machine, and formed into blocks by hydraulic pressure. The denitration of the nitrocellulose brought about by the action of the sulphuric acid on the calcium and manganese chlorides causes the finished product to be non-inflammable.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 910.)

Quinine; Influence of halogen salts on the fluorescence of ——. G. Denigès. Bull Soc. Pharm., Bordeaux; through Pharm. J., 1906, **77**, 283.

The fluorescence of a 1 per cent. solution of quinine sulphate containing 5 c.c. of pure sulphuric acid is destroyed by the addition of 3·2 c.c. of *N*/1 potassium chloride solution, 1·4 c.c. of *N*/1 potassium bromide solution, 0·9 c.c. of *N*/1 potassium iodide solution, or 95 c.c. of potassium fluoride solution. It is apparent from these numbers that equal quantities of the different halogens are required to discharge the fluorescence. If the acidity of the quinine solution be diminished, a smaller quantity of halogen salt will discharge the fluorescence, but the amount required is not proportional to the quantity of quinine present.—A. S.

Alkaloids in Strychnos leaves. Lotsy. Apoth.-Zeit., 1906, 475. Chem. and Drugg., 1906, **69**, 332.

Brucine and strychnine are present in the young leaves, but not always in the old leaves of *Strychnos nux-vomica*. On cutting the leaves the amount of strychnine appears to increase, and that of brucine to diminish. Frequently no strychnine was present in the leaves in the early morning, whereas in the afternoon it was present. The leaves of *Strychnos laurina* are free from both of these alkaloids. Strychnine is present in both the young and old leaves of *Strychnos tieuté*. The leaves of most of the species examined also contained the alkaloid, strychnicine. —A. S.

Saponarin, a new glucoside, coloured blue with iodine. G. Barger. Chem. Soc. Trans., 1906, **89**, 1210—1224.

The author gives the results of his further investigation of saponarin (this J., 1904, 1004). The air-dried glucoside has the composition, $C_{21}H_{24}O_{12}$; it is lævo-rotatory, $[\alpha]_D = -7{\cdot}90°$. When boiled for a few seconds with a large excess of acetic anhydride and a few drops of concentrated sulphuric acid, it yields an ennea-acetyl derivative, $C_{21}H_{15}O_{12}(C_2H_3O)_9$, m.pt. 183°—185° C. On hydrolysis with dilute mineral acids, saponarin yields dextrose and two apparently isomeric compounds of the formula, $C_{15}H_{14}O_7$. One of these compounds proved to be identical with the vitexin obtained by A. G. Perkin from the dye-wood of the New Zealand tree, *Vitex littoralis* (this J., 1898, 1138). The other compound, to which the name saponaretin is assigned, differs from vitexin in being readily soluble in boiling alcohol. Both substances yield phloroglucinol and *p*-hydroxybenzoic acid when fused with caustic alkali. Vitexin differs from apigenin by 2 mols. of water; it is probably a flavanone derivative containing either a reduced pyrone ring or a reduced phloroglucinol nucleus. It would thus belong to a new class of colouring matters, of which scoparin (this J., 1899, 576), considered by Perkin to be methoxyvitexin, would also be a member. Saponaretin is possibly a chalkone derivative corresponding to vitexin, or it may be identical with Perkin's homovitexin.—A. S.

Poison ivy plant [Rhus toxicodendron]; Some constituents of ——. S. F. Acree and W. A. Syme. Amer. Chem. J., 1906, **36**, 301—321.

The leaves and flowers of the poison ivy plant (*Rhus toxicodendron*) were extracted with ether. In the ethereal residue the following substances were found: Gallic acid, fisetin, rhamnose, and a poisonous tar, gum, or wax. The poison was not volatile with the vapour of alcohol or acetic acid. The poisonous tar or wax is probably of a glucoside character; it is decomposed by acids yielding gallic acid, fisetin, and rhamnose. It can be partially precipitated by lead acetate from a solution of the tar in 50 per cent. alcohol. All cases of poisoning can be easily cured with potassium permanganate. The poisonous substance can be isolated as follows: The alcoholic extract is precipitated with lead acetate. The precipitate is washed, dried, and extracted with ether. The ethereal solution is mixed with water, and hydrogen sulphide passed through. The ethereal portion is washed, and evaporated at a low temperature.—F. Shdn.

Conifer oils; Notes on some ——. R. E. Hanson and E. N. Babcock. J Amer. Chem. Soc., 1906, **28**, 1198—1201.

The authors have investigated the following oils; they are all obtained from leaves and twigs save where otherwise marked, and the chief results obtained are tabulated:—

	Yield per cent.	Sp. gr. at 15° C.	Change in sp. gr. for 1° C.
Black spruce (*Picea Mariana*)	0·57	0·9274*	0·0010
Hemlock (*Tsuga Canadensis*)	0·43	0·9255	0·0010
American larch (*Larix Americana*)	0·149	0·8816	
White spruce (*Picea Canadensis*)	0·103	0·9216	0·0013
Ditto (cones)	0·25	0·899	—
Red spruce (*Picea rubens*)	0·204	0·9289	0·0014
Ditto (cones)	0·38	0·8600	—
Pitch pine (*Pinus rigida*)	0·002	—	—
Red pine (*Pinus resinosa*)	0·001	—	—
Juniper (*Juniperus communis*)	0·18	0·8531†	—

* 19° † 20°

White spruce oil contains 25·7 per cent. of esters calculated as bornyl acetate. It differs in smell from black spruce or hemlock oil.

Red spruce oil contains 66·2 per cent. of bornyl acetate and 7·76 per cent. of free borneol. It has a very agreeable odour, suggesting bornyl acetate.

American larch oil contains 15·1 per cent. of esters calculated as bornyl acetate, and the remainder is largely pinene.—J. T. D.

Cade oil [Empyreumatic oil of juniper wood]; Characters and tests for genuine ——. C. Pépin. J. Pharm. Chim., 1906, **24**, 248—259.

Genuine cade oil should be fluid, slightly lighter than water, and have a characteristic smoky odour. The acidity, in terms of acetic acid, should not exceed 1·5 per 100 c.c. The reaction with light petroleum spirit and copper acetate (this J., 1906, 776) should give a brown colour, not green. When distilled under ordinary atmospheric pressure, at least 65 per cent. should pass over between 150° and 300° C.; under reduced pressure (65 mm.) from 70 to 75 per cent. should distil between 10° and 215° C.

Other published tests have been examined, and are found to be useless to differentiate between genuine and sophisticated oils. The oils employed by the author were authentic, having been produced under his supervision from the wood of *Juniperus oxycedrus alpha*. —J. C. B.

Colchicine; Determination of ——. A. Panchaud. XXIII., page 957.

Methyl alcohol; Detection of ——. H. Scudder and R. B. Riggs. XXIII., page 955.

Methyl alcohol; Detection and determination of —— [*in presence of ethyl alcohol*]. E. Voisenet. XXIII., page 957.

Citronella and lemongrass oils in Ceylon. Col. Off. Ann. Series, No. 494. [T.R.]

THE output of citronella oil in Ceylon (1,242,800 lb.) has increased by 80,000 lb. over that of the preceding year, the price having risen from 75 cents to 84 cents per lb. Consignments of a really pure oil, grown at the Peradeniya Experiment Station, have been sent home, and have aroused considerable interest among manufacturers.

The cultivation of lemon grass for oil has been proceeded with at the Peradeniya Experiment Station with fairly favourable results, and as the price of this oil is rising, its cultivation may prove profitable.

Attar of roses; Export of —— from Bulgaria. Bd. of Trade J., Sept. 20, 1906. [T.R.]

ACCORDING to the "Revue Commerciale du Levant" the export of attar of roses from Bulgaria in 1905 amounted to 5316 kilos., valued at 3,712,000 frs., as compared with an average of 4150 kilos., valued at 2,750,000 frs., during the preceding seven years. The principal purchasers of attar of roses in 1905 were: United States, 30·8 per cent.; France, 28·8 per cent.; United Kingdom, 16·8 per cent.; Germany, 13·4 per cent.; Russia, 4·5 per cent.; and Turkey, 4·3 per cent. The United States bought only 12 kilos. in 1897.

ENGLISH PATENT.

Carbamic acid esters of the pyrogallol-1.3-dialkyl ethers. O. Imray, London. From the Basle Chemical Works, Switzerland. Eng. Pat. 17,167, July 30, 1906.

THE carbamic acid esters of the pyrogallol-1-3-dialkyl ethers are prepared either (1) by treating the ethers with carbamic chloride, $ClCONH_2$, in ethereal solution, or (2) by causing phosgene to react with a salt of a pyrogallol-dialkyl ether, and subsequently converting the chloroformic acid ester of the pyrogallol ether into the carbamic acid ester by the action of ammonia.—J. F. B.

UNITED STATES PATENTS.

Salicylic acid menthol ether; Process for producing —— B. Bibus and R. Scheuble, Vienna. U.S. Pat. 830,043, Sept. 4, 1906.

SEE Eng. Pat. 8544 of 1905; this J., 1906, 233.—T. F. B.

Ketone; Aromatic ——, and process of making same. H. S. Blackmore, Mount Vernon. U.S. Pat. 830,044, Sept. 4, 1906.

AROMATIC ketones are obtained by oxidising aromatic hydrocarbons by means of anhydrides of "carbon oxy-acids." A keto derivative of tetrahydromethylpropyl-benzene is produced by heating a mixture of dipentene and carbon dioxide to a temperature below the decomposition point of the product; the resulting ketone is a colourless, semi-transparent substance, readily soluble in alcohol, and having a melting point of 210° C.; in its molten state it readily dissolves pyroxylin.—T. F. B.

Aldehydes; Manufacture of certain ——. G. Darzens, Paris. U.S. Pat. 830,213, Sept. 4, 1906.

SEE Fr. Pat. 360,513 of 1905; this J., 1906, 496.—T. F. B.

FRENCH PATENTS.

Camphor; Synthetic process for preparing —— from terpenes. O. L. A. Dubosc. Fr. Pat. 361,332, April 6, 1905.

OIL of turpentine or other source of terpene is dehydrated by treatment with calcium carbide, and the crude terpene saturated with hydrochloric acid gas at a temperature of 30° C. The hydrochloride is then heated with a metal and an oxidising agent to 180° C., when it is stated that camphene is formed quantitatively; suitable mixtures are molecular proportions of zinc and barium peroxide, or sodium metal and barium peroxide; it is also stated that, if manganese peroxide is used, no metal is required. The camphene thus produced is treated with an oxidising agent (chromic acid, &c.), at 180° C., when it is said to be converted into an ozonide, $C_{10}H_{16}O_3$, which loses oxygen on treatment with water, and is converted into a lactone, camphenolide; this is transformed into camphor by heating in presence of water.—T. F. B.

Lecithin; Process for the manufacture of a product containing lecithin and suitable for the extraction of free ——. E. Ziegler. Fr. Pat. 364,896, April 4, 1906.

THE germs of wheat are dried, and extracted with a suitable solvent to remove oil. They are then extracted with alcohol. The alcohol on evaporation leaves behind a residue composed chiefly of lecithin, albumin, and sugar. If this residue be taken up with 60—80 per cent. alcohol, the lecithin can be precipitated by the addition of mineral salts, and purified by known methods.—F. SHDN.

Tartaric acid and tartrates from grape residues and the like; Extraction of ——. P. P. Carles. Fr. Pat. 365,034, April 9, 1906.

PRODUCTS such as marcs, tartars, vinasses, &c., are treated with dilute sulphuric acid, so as to obtain a solution of tartaric acid. If this solution be saturated with potassium carbonate, potassium bitartrate is precipitated in a crystalline form.—F. SHDN.

Monoalkylanilines; Production of acidyl derivatives of tri- and polyhalogenated —— [for use in making celluloid]. Badische Anilin und Soda Fabrik. Fr. Pat. 365,297, April 14, 1906. Under Int. Conv., July 22, 1905.

SEE Eng. Pat. 8077 of 1906; this J., 1906, 608.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 910.)

ENGLISH PATENT.

Printing from a surface in relief; Method of ——. A. G. Bloxam, London. From Neue Photographische Ges., A.-G., Steglitz, Germany. Eng. Pat. 996, Jan. 13, 1906.

THE process consists, in general, in applying a suitable printing medium to a surface in relief, of which the parts in relief and those not in relief have a different effect on the medium, and then imprinting the medium on a suitable surface. The relief surface may, for instance, be composed of gelatin on a glass support; if this is flooded with an ethereal solution of hydrogen peroxide, the gelatin will absorb the peroxide in proportion to its mass, so that, when the peroxide has evaporated from the glass, the picture can be printed on a surface of gelatin paper or a similar surface, and developed in the known manner. Or again, the support may be prepared by treating gelatin-coated paper with potassium permanganate solution (manganese dioxide being thus formed), and the relief may consist of bichromated gelatin, in which case the hydrogen peroxide would be unaffected by the portions of the picture in relief, but would be decomposed by the catalytic action of the support.—T. F. B.

UNITED STATES PATENT.

Colour photography. W. C. South, Berwyn, Pa. U.S. Pat. 827,188, July 31, 1906.

A SUITABLE paper is coated with an emulsion of an animal glue (*e.g.*, fish glue) containing a red dyestuff, for which alizarin is recommended. It is slightly hardened by means of alum solution, and sensitised by treatment.

with an alkali bichromate solution. An image is printed on this paper from a negative taken through a suitable screen, and this image is coated with a transparent sensitive coating, which receives a blue image of the same object.—T. F. B.

FRENCH PATENTS.

Catatype pictures; Process of producing ——, *on prepared surfaces, and stable positive papers, plates, and films therefor.* Neue Photographische Ges., A.-G. Fr. Pat. 364,621, March 27, 1906. Under Int. Conv., March 31, 1905.

PAPERS or films for receiving impressions from negatives which have been treated with hydrogen peroxide, are prepared by means of substances which react with hydrogen peroxide, forming coloured products, either alone, or by the aid of some simple solution (*e.g.*, ammonia). For example, papers developed merely by treatment with a dilute solution of ammonia may be prepared by impregnating paper coated with gelatin, with a 5 per cent. solution of a manganous salt. Papers which require no subsequent development may be produced by impregnating gelatin-coated paper with cobalt salts, *e.g.*, with a 10 per cent. solution of the acetate. This process can also be applied to the catalytic preparation of prints similar to "carbon" prints, by incorporating a suitable pigment with the gelatin coating of the paper.—T. F. B.

Photographs in colour; Process for preparing ——, *by superimposing the various coloured monochrome images, produced on detachable layers of silver emulsion.* Chem. Fabr. auf actien, vorm. E. Schering. Fr. Pat. 365,314, April 14, 1906.

EACH of the monochrome positives, except that which is first applied to the permanent support, is printed on a layer of silver emulsion, detachably mounted on a thin sheet of mica, celluloid, &c., which renders superposition in register easy, owing to the transparency of the temporary support.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

(*Continued from page* 911.)

Phosphorus in presence of large quantities of phosphorus sesquisulphide; Detection of small quantities of white ——. L. Aronstein. XXIII., page 955.

ENGLISH PATENTS.
